7021. SCHNEIDER, EDWARD C., and GORDON C. RING. The influence of a moderate amount of physical training on the respiratory exchange and breathing during physical exercise. *Amer. Jour. Physiol.* 91(1): 103-114. 1929.—Moderate physical training, about an hour daily, increased the load-carrying ability [in 2 subjects] within 1 wk. but the full effect was observed only after 5-7 wks. Any let down in the regularity or amount of daily work soon reduced the load-carrying ability, but even with complete neglect of exercise some of the gain in power was maintained for several months. The percentage of CO_2 exhaled and of O absorbed during work was increased by training, the full effects being reached within 4 or 5 wks. These soon dropped back to the pre-training level when training was discontinued. The minute-volume of breathing for any given load of work decreased with training, and reached its lowest level in 4-6 wks. This effect disappeared within 4-6 wks. after training was discontinued. In 1 subject the absorption of O was increased as training changed overloads to normal or crest-loads. In another subject a slight decrease in the O consumption of work was evidenced as training proceeded. A decrease in the respiratory quotient of work during training suggested a gain in ability to more adequately reconvert lactic acid into its precursor. The effects of physical training were manifest, in the subject sitting at ease, by a higher percentage output of CO_2 and intake of O and by a higher metabolism per sq. meter of body surface.—*Authors' summary.*

7022. SHAW, LOUIS A., and ANNE C. MESSER. The carbon dioxide capacity of the body and the rate at which the body comes into equilibrium with changes in the alveolar carbon dioxide tension. *Amer. Jour. Physiol.* 93(2): 422-432. 1 fig. 1930.—In 10 experiments cats were made to breathe from a gas mixture containing about 11% CO_2 until equilibrium had been established at a level which was about 54 mm. Hg above the normal. During the return to the normal level, while the cat breathed outdoor air, the expired air was collected, and the CO_2 which was in excess of that produced by oxidation during the collection period represented that which had been retained by the body as a result of the previous saturation to a higher CO_2 level. One kgm. of cats' blood, within the CO_2 tension limits of these experiments, will retain about 3.2 cc. CO_2 per mm. of Hg tension difference, while the entire body under the same conditions will retain about 1.78 cc. CO_2. The CO_2 retained by the blood alone was 10.5% of that retained by the entire body. On the assumption that the body is 70% water by weight and that the CO_2 retained by the body is held by the water of the body, the authors estimate that 1 kgm. of tissue fluid, exclusive of the blood, will retain an average of 2.49 cc. CO_2 per mm. tension difference. In 30% of their experiments the buffering capacity of the tissue fluids was equal to or greater than that of the blood. It requires 45-140 min., with an average value of 102 min., for the body of the cat to come into equilibrium with a change in the alveolar CO_2 tension.—*Authors' summary.*

7023. SHAW, LOUIS A., and ANNE C. MESSER. Cutaneous respiration in man. II. The effect of temperature and of relative humidity upon the rate of carbon dioxide elimination and oxygen absorption. *Amer. Jour. Physiol.* 95(1): 13-19. 1 fig. 1930.—The rate of CO_2 excretion and O absorption through the skin of the arm was observed at different temperatures and a constant relative humidity, and at different relative humidities and a constant temp. [in a single subject]. The rate of CO_2 excretion increases with rising temp. At 34° C., there is a critical point above which the rate of CO_2 excretion becomes 6 times as rapid per degree of temp. increase as at temp. below 34° C. The O absorption bears an approximately constant ratio to the CO_2 excretion until 34° C. is reached, at which point the ratio of CO_2 excretion to O absorption becomes greatly increased. The rate of cutaneous respiration increases with the relative humidity due to the thermal effect of evaporation.—*From authors' summary.*

7024. TURNER, ABBY H. Vital capacity in college women. I. Standards for normal vital capacity in college women. II. A study of students with high and low vital capacity. *Arch. Internal Med.* 46(6): 930-937; 938-945. 1930.—I. A study of the vital capacities of 1,337 freshman college women is summarized. The correlation with standing height is the best and with surface area only slightly less good. As previously determined, the weight correlation is distinctly less close. II. A comparative study of students whose vital capacity was more than 15% above or below the average for their heights (121 with high and 85 with low vital capacity). While in a few instances there seemed to be direct association of low vital capacity with past or present disease of the thorax, heart or lungs, the majority seemed to be young women for whom the exercise program in the years previous to college was very limited. The response of 22 students in 1 class, specially trained for thoracic development, was gratifying. By whatever test this low vital capacity group was tried out (general health, academic or social success), it appears that it was at a disadvantage.

7025. WILLIAMS, DONALD H. The production of tetany in albino rats through decreased atmospheric pressure. *Trans. Roy. Soc. Canada (Sect. 5, Biol.)* 23 (2): 143-150. 1929.—Gradual reduction of O tension in the air breathed by young white rats produces death from uncomplicated asphyxia, from tetany preceded by asphyxial symptoms, or from tetany not preceded by asphyxial symptoms. The essential factor determining which series of events will occur is the rate of fall of O pressure. The average rate of fall for 3 cases was .50, .61 and .73 mm. Hg per minute respectively. The results agree generally with the diphasic theory of the effects of anoxemia.—*H. M. Krueger.*

7026. YSSELING, M. A. Über die Atmung der Weinbergschnecke (Helix pomatia). *Zeitschr. Wiss. Biol. Abt. C, Zeitschr. Verglcich. Physiol.* 13(1): 1-60. 6 fig. 1930.—A capillary tube containing fluid was inserted into the lung, the column rising when the lung closed, lowering when it opened. When closed, movements occurred which increased in intensity when an unfavorable condition persisted and decreased when free respiration again occurred. Respiratory movements began when the O content of the lung apparatus sank below 9-11%; under normal conditions there was no regulation of diffusion. When the degree of moisture changed, *Helix* responded by keeping the respiratory opening open. The reaction occurred in the direction dry-moist and moist-dry; movements of air and absorption of CO_2 could suppress it. In an N atmosphere the lung opened and closed in rapid succession (panting). This did not occur in an atmosphere of more than 11% O, appeared when it was below 9-11% O. If the 9-11% atmosphere was replaced by one of 20% O the lung was open for a long time (open reaction). CO_2 did not alter the re-

action to O deficiency or excess-respiratory movements, panting and the open reactions persisting. It is probable that CO_2 exerted an effect on the amount of respiratory opening, since an accumulation of CO_2 in the region of the opening caused further opening. An open reaction occurred when the shell was closed airtight, the snail being indrawn. This was apparently caused by the CO_2, which had an effect because respiratory movement was absent. The regulation of respiratory movement (regulating factor O deficiency) was apparently central; that of the size of the opening peripheral. Analyses showed that the O mechanism was not used in the lungs below 11%, respiratory movements beginning at this content. The O consumption was greatly influenced by the appearance of CO_2. Closing of the lungs initiated an inhibition of cardiac activity, particularly in an O-poor medium. O deficiency had little influence on cardiac activity; in a N medium the heart often beat as rapidly during the open period as in the O medium. CO_2 had a pronounced action on the cardiac activity, the frequency becoming less (even when sufficient O was present). Though the frequency was low under the influence of CO_2, it increased when the temperature was increased.

Physiol.* 227(1/2): 171-180. 6 fig. 1931.—Mechanical relations of various muscles and their modification by change of posture and point of fixation of the limb are analysed. The principle is emphasised that muscles which are antagonists for one movement may be synergists for another. Reflex factors in coordination are not dealt with.—*G. P. McCouch.*

7028. **BANCROFT, WILDER D., and GEORGE BANCROFT.** Glycogen metabolism. *Proc. Nation. Acad. Sci.* 16(10): 651-657. 1930.—The authors criticise the theory that the recovery process in muscle after activity involves the coupled reactions of oxidation of lactic acid and conversion of lactic acid into glycogen. Instead, they postulate that these reactions are independent, and that a reversible equilibrium, catalyzed by enzymes, exists in muscle between glycogen or glucose, and lactic acid. Displacement of this equilibrium occurs when adsorption of glycogen by protein is decreased, as when a muscle is stimulated. They suggest that in cancer the adsorptive power of protein for glycogen is very low.—*M. Dann.*

7029. **BAUER, ERWIN, und M. TSCHUKITSCHEWA.** Über ausgleichende Vorgänge beim Absterben lebender Systeme. II. *Pflüger's Arch. Ges. Physiol.* 223(1/2): 104-112. 5 fig. 1929.—Dead tissues from white rats and mice and fresh tissues from normal animals, from animals fatigued by exercise, and from muscles tetanized by induction currents, were placed in distilled water and the increase of weight with time was determined together with the changes in lactic acid and glycogen content of the muscles. Dead tissues or fatigued tissues swell to a maximum weight and thereafter the water content remains constant, while fresh live tissues shrink for some time after the maximum water uptake, which is reached in 2-4 hrs. Accompanying the water uptake in fresh tissues is an increase of lactic acid and decrease of glycogen contents; with the subsequent shrinking stage, the reverse. Thermodynamic calculations of the energies involved in swelling and shrinking and in the conversion of glycogen to lactic acid and vice versa lead to the conclusion that this swelling and shrinking is simply a long drawn out contraction and relaxation of the muscle by the normal contractile mechanism.—*J. M. Ort.*

7030. **BLASCHKO, H.** The delayed anaerobic heat production of stimulated muscle. *Jour. Physiol.* 70(1): 96-100. 1930.—The delayed anaerobic heat production after a tetanus has been subjected to a critical examination. It is not due to condensation of water vapor caused by a possible temporary rise of osmotic pressure, nor is it due to non-uniform heat production in contraction or control. Its occurrence has been verified, and it has exhibited the usual variability and order of size. It seems to be due to some real process occurring in the muscle.—*Author's summary.*

7031. **BLUME, WILHELM.** Über die Erstickungsstarre an Fröschen. *Arch. Exp. Path. u. Pharm.* 127 (3/4): 165-172. 1928.—When water in which *Rana temporaria* is immersed is warmed to 33-34° reversible rigidity of muscles develops. Temp. required is lower than that needed for heat narcosis (35°), and this rigidity develops more rapidly than the peripheral heat rigor of muscle. It resembles the rigidity of narcosis, asphyxia, or decerebration in cats, being prevented by section of posterior roots, but differs from them in depending upon centers in the entire central nervous system, brain as well as cord. Before rigidity develops there are convulsions. The entire picture is attributed to asphyxia, resulting from increased O consumption because of heat, with no corresponding increase in O supply. —*C. F. Schmidt.*

7032. **BRAMWELL, CRIGHTON, and REGINALD ELLIS.** Some observations on the circulatory mechanism in Marathon runners. *Quart. Jour. Med.* 24(95): 329-346. 2 pl. 1931.—A group of 28 Marathon runners, examined clinically, radiographically, and electrocardiographically during their final stage of training, consisted of older, more phlegmatic men, of lighter build and with a slower heart rate than that of other Olympic runners, and with hearts relatively larger than those of any other group of athletes examined. Of the first 7 places, 5 were taken by men whom the authors had previously examined; no constant physical finding served to differentiate them from less successful competitors. It is suggested that the smallness of the O debt probably accounts for the absence of distress among Marathon runners, and that shortage of glycogen is one of the most important factors in determining the limits of their endurance.

7033. **BRISCOE, GRACE.** Adequate electrical stimuli for posture and movement. *Jour. Physiol.* 71(3): 292-308. 1931.—The quadriceps muscle of the cat was so arranged that in full postural contraction the leg and foot were held straight up in the air. The leg was denervated except for the experimental muscle. Low rates of stimulation (20-25 per sec.) will maintain posture for hrs.; higher rates are suitable for rhythmic phasic contractions. Prolonged postures have been obtained under ether anesthesia alone, dial alone, and under a combination of these 2 drugs. There is a limited range of rates within which full steady posture can be held without sign of fatigue; rates below or above this range lead either to tremulous action or to decline of posture. There is no hard and fast line between the stimuli for tonic and the stimuli for phasic activities in the muscle. Comparing the conditions found in decerebrate rigidity with those necessary for exhibiting artificial posture, a close parallelism is observed. This suggests that the electrical stimuli employed in the latter case may be termed adequate, since they produce effects similar to those resultant from natural stimuli.

7034. BROWN, MARION, and C. G. IMRIE. On the creatine and phosphorus content of muscle. *Jour. Physiol.* 71(2): 214-221. 1931.—Determinations on 31 muscles removed from 20 cats indicated that, as a rule, in the muscles of normal cats when the amt. of creatine is high the total acid-soluble P and the proportion of it present as phosphagen are also high. Occasionally the total creatine is greater than the phosphagen. When the concentration of creatine in the muscles is increased following the absorption of creatine introduced into the duodenum, there is evidence that the concentration of total acid-soluble P is also increased.

7035. CASTEX, M. E. Méchanisme du soulèvement du corps sur la pointe des pieds. *Jour. Physiol. Path. Gén.* 28(3): 544-555. 10 fig. 1930.—In the movement of extension on the leg, the foot is always a lever of the 1st order, the fulcrum being the tibio-tarsal joint. When the thrust is taken by the point as in rising on tip-toe, the foot becomes, in addition, a lever of the 3rd order. Similarly, in flexion of the fore-arm, as when trying to raise a fixed weight, the radius forms a lever of the 3rd order of which the fulcrum is the shoulder.—*W. R. Fearon.*

7036. DAVENPORT, H. A., HELEN K. DAVENPORT, and S. W. RANSON. Chemical studies of muscle contracture. 4. Changes in phosphorus, nitrogen, and fat produced by tetanus toxin. *Jour. Biol. Chem.* 87(2): 295-298. 1930.—The changes in acid-soluble P found during tetanus contracture consisted of a reduction in the total P (proportional to the protein N), a decrease in phospho-creatine which was somewhat greater than would be accounted for by water change in the muscle, and an inconstant variation of other fractions. The fat content was increased 10% in the tetanus muscle in 3 and essentially unchanged in 2 animals. It therefore seems to have no significance for the acute stage of contracture. —*Authors' summary.*

7037. DAVIS, LOYAL, and LEWIS J. POLLOCK. Studies in muscle tone. II. Resiliency of muscles in decerebrate rigidity. *Amer. Jour. Physiol.* 89(2): 395-399. 1 fig. 1929.—Further proof is advanced that a muscle intoned by a tonic labyrinthine reflex undergoes a change in its physical properties. Not only is such a muscle similar to gum in that it may be "pulled out" and remain so, but when it is compressed and the compression then removed, it remains indented and a part or the entire amt. of the bulging produced by the tonic reflex is "pressed out." The resiliency of a muscle intoned by a tonic labyrinthine reflex is diminished in comparison to that of a normal muscle.—*Authors' conclusions.*

7038. DJURICIC, ILIJA. De la sensibilité envers l'anode du muscle des grenouilles d'hiver. [The anodal sensitivity of muscles of the winter frogs.] [In Serbian, with French résumé.] *Bull. Acad. R. Serbe Sci. Arts Belgrade* 135(64): 57-94. 1929.—Muscles of winter frogs excited by a strong induced current traversing the entire length of the muscle are less reactive than those of summer frogs. Narrow electrodes are placed at one end of a muscle and the muscle is excited by means of strong induced currents in such a way that at one time the cathode, and at another the anode is nearer the mass of the muscle. In the first case the muscle responds by maximal twitches all of the same height; in the second, the reaction is reduced because the wave of excitation must cross the region of anelectrotonus. During the passage of an induced current from end to end of a muscle there are formed in the excited muscle numerous secondary electrodes at each of which is produced a similar condition of anelectrotonus which, by diminishing excitability, diminishes contraction. Later only a constant current of long duration (1-5 min.) would provoke the anelectrotonic modification. Towards November 15th, it manifested itself at the make of the constant current; therefore the induced current was just able to produce the effect. According to the author, this is the first stage of hibernation. The 2nd stage occurs in late December or early January when weak induced currents produce the anelectrotonus. At the end of this stage, the anelectrotonus becomes so marked that the excited muscle reacts no longer if the anode is nearer the main mass of muscle. In February or March anelectrotonus can be produced by an induced current which passes from end to end of the muscle. It appears from this that the secondary anodes throughout the muscle show with difficulty their anelectrotonic action.—*Author's résumé (transl. by J. M. D. Olmsted).*

7039. DJURICIC, ILIJA. Action du courant constant sur les muscles squeletiques des grenouilles d'hiver, de printemps et d'été. [In Serbian with French résumé.] *Bull. Acad. R. Serbe Sci. Arts Belgrade* 135(64): 97-101. 1929.—Muscular contraction resulting from the break of a constant current of sufficient intensity is due to excitation by a current of polarization which develops in the muscle during the passage of the constant current. The effect of the polarization current is easily manifest when a current of moderate intensity passes throughout the entire length of the muscle, but less easily so when the muscle is excited at one end only. In winter frogs the break of even a very strong current (20 v.) passing from end to end of the muscle has no effect. Therefore during hibernation the sensitivity of the muscles is greatly reduced. When these results are compared with the results on nerve (Pflüger's Laws) it will be seen that muscles of winter frogs, in contrast to those of summer frogs which obey the first and second parts of this law only, obey the first and third parts of this law, and not the second.—*Author's résumé (transl. by J. M. D. Olmsted).*

7040. EGGLETON, PHILIP. The diffusion of creatine and urea through muscle. *Jour. Physiol.* 70(3): 294-300. 1930.—By observing the diffusion of creatine into or out of muscles immersed in salt solutions containing creatine, it has been shown that a concentration of 80 mgm. of creatine per 100 cc. of solution is just sufficient to prevent loss of creatine from a resting muscle (frog's sartorius). If the equilibrium were a simple osmotic one, this would indicate a concentration of 65 mgm. of creatine per 100 gm. of muscle (80 mgm. per 100 cc. of water in the muscle). This figure of 65 mgm. per 100 gm. has been previously obtained by direct chemical analyses. Only 1/5 therefore of the "total creatine" of resting muscles is actually present as creatine. In the case of fatigued muscles equilibrium is obtained at concentrations of 200 to 300 mgm. creatine per 100 cc. of solution. It seems probable, therefore, that stimulation to fatigue trebles the amount of free creatine. Urea distributes itself between resting muscles (frog's sartorii) and surrounding isotonic salt solutions in such a manner as to indicate that the whole of the water in the muscles is capable of dissolving urea.—*Author's summary.*

7041. FENN, W. O., H. BRODY, and A. PETRILLI. The tension developed by human muscles at different velocities of shortening. *Amer. Jour. Physiol.* 97(1): 1-14. 2 fig. 1931.—Graphical records were taken of the swinging of the arm from the shoulder and the leg from the knee. Velocity of movement was determined and from the change in velocity with time the acceleration and hence the forces exerted by the muscles at different parts of the swing were deduced. The force exerted by the muscles when the limb was held isometrically was determined at the moment when the limb was suddenly released. From the resulting acceleration of the limb as deduced from the graphic record of the swing the moment of inertia of the limb was calculated and agreed within 10% with the value estimated from the weight of the individual and the dimensions of the limb. When the force exerted in such a "quick release" experiment was plotted against the velocity at different moments during the swing, it was found that the tension decreases as the speed of movement increases (av. rate of decrease—3.1% for a rate of shortening of 10% of the muscle length per sec.). It was concluded that this represented a maximum figure for the effect of viscosity alone. A similar constant calculated from Hill's data gave 7.3%, probably because reflex inhibition contributed to the decrease of tension.—*Authors' summary.*

7042. **FENN, WALLACE O. Work against gravity and work due to velocity changes in running: movements of the center of gravity within the body and foot pressure on the ground.** *Amer. Jour. Physiol.* 93(2): 433-462. 1 fig. 1930.—From measurements made on moving picture films of sprinters, figures are obtained from which some of the work done in running can be calculated. The movements of the center of gravity within the body due to changes in the positions of the limbs are determined. Both arms and legs tend to raise the center of gravity within the body at the end of the period when the foot is in contact with the ground, the total average rise being 2.9 cm. Simultaneously the body itself rises an average distance of 3.1 cm., the total rise of the center of gravity in relation to the ground being therefore 6 cm. This rise occurs while the foot is on the ground. The corresponding rate of energy expediture is 0.215 H.P. Backward and forward movements of the limbs are largely compensatory on the 2 sides of the body. The velocity of the head is greater than that of the pelvis while both feet are in the air but the reverse is true while either foot is in contact with the ground. The changes in velocity of the pelvis are not so great as they appear to be from direct measurement of the film because there is a compensatory movement of the center of gravity within the body which is shown to move backwards when the apparent forward velocity of the pelvis is at a maximum. An apparatus is described by which the horizontal pressure of the foot on the ground is measured during sprinting. During each period of contact there is first a forward pressure and then a backward one. This constitutes a direct method of measuring energy loss due to fluctuations in the forward velocity. The forward pressure on the ground represents for the whole run a loss of 0.34 H.P. and the backward pressure an expenditure of 0.5 H.P. The difference of 0.16 H.P. is due to wind resistances. The loss of velocity due to contact of the foot with the ground is 13 cm./sec. as measured on the special apparatus (running platform) described and it is 12-24 cm./sec. when calculated from the vector velocity of the center of gravity of the runner and the angle of contact with the ground.—*Author's summary.*

7043. **FENN, WALLACE O. A cinematographic study of sprinters.** *Sci. Monthly* 32(4): 346-354. 4 fig. 1931.—A semi-popular summary of work described in abstracts vol. 5(5): Entry 14133, and in this issue 7041 and 7042. —*W. O. Fenn.*

7044. **FISCHER, E. Die Wärmebildung des Skeletmuskels bei aufgehobener Milchsäurebildung.** *Pflüger's Arch. Ges. Physiol.* 226(4/5): 500-517. 1931.—With the help of the Hill-Hartree method of thermoelectric measurement, the amount and course of the heat production of muscles (sartorius) poisoned with monobromacetic acid were determined. The poisoning was produced by injection into the lymph system of the frog or by immersion of isolated muscles in Ringer's solution containing monobromacetic acid. The caloric quotient of the poisoned muscles was unchanged. Under aerobic conditions, the poisoned muscle had the same heat production as a normal muscle under anaerobic conditions. The poisoned muscles showed no recovery heat production. The partition of initial heat showed no alteration. It may be concluded that the changes in muscle chemistry which result during contraction after poisoning with monobromacetic acid have to do only with secondary changes of the contraction process.—*D. W. Wilson.*

Therap.* 39(4): 136-150. 7 fig. 1930.—A general discussion of the neuromuscular apparatus, its relation to work, maintenance of posture, fatigue and efficiency. Some of the author's own experiments with the ergograph point to the importance of mental factors in muscular contraction and fatigue. Absolute muscle force is a relative term, since force depends upon psychic effort.—*H. S. Hopkins.*

7046. **HARVEY, E. NEWTON. The effect of high frequency sound waves on heart muscle and other irritable tissues.** *Amer. Jour. Physiol.* 91(1): 284-290. 1929.—High frequency (340 kilocycles) sound waves of high intensity will cause rhythmic contraction of quiescent ventricular muscle of frog or turtle immersed in Ringer's solution and a more rapid natural rhythm of the auricles accompanied by lessened amplitude of contraction and often by increased tone. Touching ventricle or skeletal muscle or nerve to glass carrying intense supersound waves does not stimulate. Smooth muscle of the alimentary tract exhibits some contraction from supersonic stimulation but the effect is negligible compared with that of heart muscle. Curarized gastrocnemius is not stimulated. The effect may be due to increased pressure changes accompanying the sound waves since it is known that increased pressure will stimulate.—*Author's summary.*

7047. **HINTZE, A. LAURA, and LLOYD SEAGER. The tonus of the ear muscles in the rabbit after cutting the cervical sympathetic.** *Amer. Jour. Physiol.* 89(2): 400-402. 1929.—After section of 1 cervical sympathetic, 9 of 11 rabbits showed a slight drooping of the ear on the operated side which may be interpreted as a slight loss of muscular tonus due to the vasodilation and consequent sudden rise in temp. of the ear muscles. After a few hrs. no difference could be distinguished between the 2 ears (observed up to 23 days). Both ears reacted alike to rubbing with alcohol, fatigue from weights and sudden changes in temp. There was thus nothing disclosed justifying a belief that the cervical sympathetic had any direct influence on the tonus of the ear muscles. —*Authors' summary.*

7048. **HORTON, H. V. The reversible loss of excitability in isolated amphibian voluntary muscle. II. A comparison of the inexcitable condition obtained by different methods. Chronaxie and potassium diffusion.** *Jour. Physiol.* 70(4): 389-403. 1930.—Sartorius muscles (*Rana esculenta*), which have been well soaked in Ringer's solution, can be made reversibly inexcitable by treatment with CO_2 or Ringer's solution at pH 5.5, by damage with pin pricks and by soaking in solutions containing large amounts of K or small amounts of Na. The inexcitability so produced is analogous to that which ensues spontaneously in a muscle dissected without the use of Ringer's solution and suspended in a moist gas, etc. Inexcitable muscles lose K while excitability is being regained by soaking in Ringer's solution. With the onset of the inexcitable condition the values of rheobase and chronaxie rise, to fall again to normal with recovery of excitability. Sartorius muscles will lose up to 70% of their total K if soaked in Ringer's solution for 2 days. The loss of K from muscles may be considerably delayed if the Ringer's solution used for the diffusion contain about 4 times the normal amount of K. A high K/Na ratio in the fibres and a low one in the interspaces may be necessary for excitability. Permeability of some of the fibres may alter these ratios. The diffusion of K and the possible effect of plasma on this diffusion are discussed. Modifications in the method of Kramer for estimating K are described.—*Author's summary.*

Physiol.* 226(3): 323-346. 14 fig. 1930.—Four reactions were employed to indicate tonic characteristics: acetylcholin contracture, nicotine contracture, a plastic response to stretch, and contracture which followed galvanic stimulation was prevented by atropine and novocaine. It is maintained that postural function and reflex tonus are not related to these reactions, which are associated with the phylogenetic age of the muscles.—*G. P. McCouch.*

7057. RUSHTON, W. A. H. Excitable substances in the nerve-muscle complex. *Jour. Physiol.* 70(4): 317-337. 2 fig. 1930.—In this paper an attempt has been made to learn whether in the nerve-muscle complex there exist an α and a γ substance, or whether the claims of Lucas to this effect have been due to experimental errors. The sartorius muscle was immersed in a trough of Ringer's fluid through which the current could be sent in parallel lines at various angles with the muscle. Since the optimum angle for the α substance is often quite different from that for the γ substance, this method allows the 2 to be distinguished and hence strongly supports Lucas. Evidence for 2 excitable substances is obtained by 2 different criteria. First, the strength-duration curve of the muscle shows a break which is well outside the limits of error; 2nd, the variation of threshold with angle shows a transition from a substance in the direction of the muscle to one (usually) at a different angle. The α and γ curves may be obtained at all stages from a spinal animal to an excised muscle after 24 hrs. equilibration with Ringer. The γ substance, which is isochronous with nerve, so far from being the excitable substance of the normal muscle fibre, lies in a direction which is usually quite different, and appears to be absent from the pelvic extremity of the sartorius; the α substance, on the contrary, seems to have the properties of the excitable element of the muscle fibre, both with regard to its direction and distribution.

7059. SCHNEIDER, EDWARD C. A study of responses to work on a bicycle ergometer. *Amer. Jour. Physiol.* 97(2): 353-364. 1931.—A linear relationship between the amount of O absorbed and the load of work was maintained by all subjects during moderate exertion. In 4 of 6 cases, the linear relationship was broken soon after the crest-load was passed. The pulse frequency also, like O absorption, augments roughly in a linear relationship to the increase in work up to a certain load, which is found to vary from man to man. The O-pulse rises steadily with an increasing load of physical work, and gives a plotted curve with the concavity towards the abscissa, except for the heaviest loads. The minute-volume of breathing for the 4 subjects who reacted well maintained a linear relationship to the load of work up to the crest-load. For larger loads the increase in lung ventilation becomes excessive and diverges upward from the normal line of augmentation. There is a tendency for the frequency and depth of breathing to increase proportionately with the load up to or just above the crest-load. With overloads of work the frequency of breathing augments inordinately. The limit of voluntary physical effort in 2 cases seemed to be due primarily to failure of the heart to augment proportionately to the increased demands of the tissues for O. Another limiting factor was indicated in the failure of the O-pulse to augment in the usual degree. This is interpreted to be due to an inability to adequately increase the coefficient of utilization of O.—*Author's summary.*

7060. SERENI, ENRICO. Notizie sulla produzione di calore nei muscoli lisci. [Heat production in smooth muscles.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1045-1050. 1930.—In *Sipunculus nudus*, Holothuria and *Stichopus regalis* the heat production by smooth muscles as related to muscular contraction showed 2 distinct stages: (1) a non-oxidative one, related to contraction and relaxation; (2) an oxidative one, related to recovery. In smooth muscles the maintenance of musclar tension was always accompanied by heat production.—*M. Comel.*

7061. SMITH, PAUL W., and MAURICE B. VISSCHER. On the source of energy for anaerobic contraction in glycogen-poor muscle. *Amer. Jour. Physiol.* 95(1): 130-138. 1930.—Experiments on 48 grass and bull frogs, using the procedure of Olmsted and Coulthard, and 15 large bull frogs, with a modification of the procedure to allow the measurement of developed tension as well as glycogen and lactic acid, showed that within the limits of experimental error the lactate accumulation in anaerobic contraction to fatigue is entirely balanced by the loss in glycogen in glycogen-poor, as well as in glycogen-rich muscle. In 24 experiments recording isotonic contractions the authors have found that the magnitude of the mechanical response is invariably proportional to the quantity of lactate formed from glycogen. From these studies there is no evidence that the energy for tension development in muscle poor in glycogen arises from a different source than in muscles rich in glycogen.

7062. SOLARINO, GIUSEPPE. Comportamento del fosfogeno e dei fosfati nei muscoli dopo azione del bagno freddo. [Action of cold baths on phosphagen and phosphate content of muscles.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1001-1003. 1930.—Only slight decrease of phosphagen and phosphates followed cold baths in dogs.

No marked variation followed exercise (massage, running) after the bath.—*M. Comel.*

7063. **STIASNY, GOTTFRIED. Permeabilität und Ermüdung. IV. Der Wendungseffekt bei tetanischer Reizung.** *Pflüger's Arch. Ges. Physiol.* 225(2/3): 230-264. 11 fig. 1930.—The gastrocnemius muscles of frogs were given tetanizing stimuli of A. C. and of half- and completely rectified A. C. The tetanic contractions when produced by the rectified A. C., as has been found for rhythmic condenser discharges, can be repeated after recovery by the reversal effect. This is not so with tetany produced by A. C. The observation of Ewert that the form of the contraction curves depends on the direction of current flow holds also for tetanic contractions. For tetanizing stimuli also, it was found that, at the beginning of an experiment, the speed of recovery with rest was nearer to that caused by the reversal effect, while later on, after more work had been done, again the reversal effect was much more speedy, and could be effective when rest no longer could bring about any recovery. In agreement with theory, a muscle tetanized by A. C. does not react to a half-rectified current of equal maximum amplitude but does if the amplitude is greater. Hence also, with A. C. the fatigue is localized at the cathode but in this case in two halves at the two electrodes. If a muscle is being tetanized by pulsating D. C., A. C. will then cause the muscle to do work. Towards the end of the experiment, however, the irritability to A. C. disappears, but can be again regenerated by a brief renewal of the stimulation with pulsating D. C. after the A. C. has been tried. Rest will also restore this irritability to A. C. under these conditions, if the experiment has not gone too far. With fresh muscle, half rectified A. C. is more irritating in spite of its lower current frequency and average current strength, while with a more fatigued muscle, fully rectified A. C. is the more so. A. C. is more so than either in both cases, and is effective when the other two can no longer cause a response. These results also indicate that the fatigue in isolated frogs muscle is a membrane phenomenon and is concerned with ion aggregations at these surfaces. Hence, as has often been observed, A. C. exerts a reversible effect on the central nervous system.—*J. M. Ort.*

7064. **THÖRNER, WALTER. Untersuchung über die polare Erregung des Muskels bei Degeneration und im Kationenantagonismus.** *Pflüger's Arch. Ges. Physiol.* 222(1/2): 37-51. 1929.—This paper is concerned with the fibrillation of striated muscle which occurs after denervation. Frogs (100 *Rana temporaria*) were used. One half centimeter of the sciatic plexus was excised on one side and survival permitted. After a few weeks to 3 mos. the normal and denervated muscles were observed simultaneously in a comparison microscope. Fibrillation was the striking feature of the denervated muscle. Passage of a galvanic current through the denervated muscle and solutions of NaCl and KCl increase the fibrillation. Thörner infers from his results that denervation increases the permeability of the muscle cell. No mention is made of the related work of Langley and Stevens.—*H. C. Stevens.*

7065. **TUTTLE, W. W., and R. C. WILKINS. The application of the pulse-ratio test to efficiency in performing on gymnasium apparatus. The horizontal bar.** *Arbeitsphysiologie* 3(6): 449-455. 1 fig. 1930.—The pulse-ratio test is the effect of light exercise of graded intensity on the heart rate and is found by dividing the pulse rate for two minutes after the exercise by the resting pulse rate for one minute. The most practical way to obtain it is to have the number of trials which produce a pulse-ratio of less than 2.5 and a number of trials which produce a pulse-ratio of more than 2.5 and then interpolate to obtain the number of trials necessary to produce exactly a pulse-ratio of 2.5. The norm was first established in 5 different exercises on the horizontal bar with an efficient subject in excellent physical condition. Thirty subjects were then selected at random from classes in physical education. Most of them produced a pulse-ratio in less number of trials than the norm. The conclusion is that the pulse-ratio test is an index to efficiency in performance on the horizontal bar, an index to the comparative difficulty of the exercises, and that practical application may be made of the pulse-ratio test in following the progress of students in the horizontal bar technique.—*T. M. Carpenter.*

7066. **UFLAND, I. M., und L. W. LATMANISOWA. Einfluss der Arbeit auf die Chronaxie des Nerven-Muskelapparates des Menschen.** *Arbeitsphysiologie* 3(5): 360-371. 1930.—The influence on the chronaxie and rheobase of the position of the hand and arm at angles of 140°, 90° and 30° and holding a weight of 2 kgm. was studied and no alterations were found. Dynamic work with a hand ergometer was performed by 50 men. It consisted of raising a weight of 12 kgm. 25 cm. rhythmically 120 times a min., changing from one hand to the other. There was an average increase of 14% in chronaxie and rheobase of the biceps muscle. About ½ of the subjects showed an increase, whereas a majority of the remainder showed no alteration. After static work there was no alteration in chronaxie of the biceps muscle, but a tendency to increase in the rheobase. The lifting of a weight by flexing the hand at the wrist caused an increase in the muscle chronaxie. The chronaxie of the nerves of the corresponding muscles remained unaltered. Work with the feet caused an increase in the chronaxie of the biceps.—*T. M. Carpenter.*

7067. **VISSCHER, MAURICE B., and PAUL W. SMITH. The relation between contraction frequency and lactate accumulation, and its bearing upon the economy of tension production and maintenance in striated muscle.** *Amer. Jour. Physiol.* 95(1): 121-129. 1930.—The production of lactic acid in contraction in relation to the interval between contractions has been investigated by comparing the lactate concentration in 1 gastrocnemius muscle of a frog after stimulation at a given frequency with that of the other gastrocnemius treated identically and stimulated the same number of times but at another frequency. In 25 experiments in which the 2 opposite gastrocnemii were treated exactly alike except for frequency of stimulation, it was found that the lactic acid produced per contraction in the frog's gastrocnemius is inversely proportional to the frequency of stimulation. It is found that the lactic acid coefficient of developed tension is a more constant factor than is the coefficient of total maintained tension. The latter is very different at various frequencies of contraction, whereas the former is nearly a constant. The total tension coefficient is a measure of economy of tension maintenance in contraction, and indicates a marked increase in efficiency of tension maintenance at higher frequencies. The slow rate of removal of lactic acid is of advantage to the organism in those muscles where the maintenance of tension is an important function. Fatigue contracture appears, in the light of the experiments reported, to be due to the depletion to a very low level of the store of base for neutralizing free lactic acid.—*Authors' summary.*

7068. **WERESTSCHAGIN, N. Untersuchungen über Muskeltonus und Ermüdung. (Neue Methode zur Bestimmung des Dehnungwiderstandes des Muskels.)** *Pflüger's Arch. Ges. Physiol.* 227(1/2): 188-203. 10 fig. 1931.—A method is described for measuring the resistance offered by the flexors of the knee to knee extension when the thigh is flexed. The method is similar to that of Spiegel for the quadriceps femoris. Both extent of movement and applied tension are recorded. Percentage lengthening of muscles is calculated. Normals show a characteristic curve from which pathologic cases deviate. Fatigue is followed by immediate decrease, soon followed by increase in resistance to passive extension. —*G. P. McCouch.*

7069. **WHITE, M. M. Relation of bodily tension to electrical resistance.** *Bull. Univ. Oklahoma (Proc. Oklahoma Acad. Sci.)* 9(456): 165-171. 1929.—In general there was a higher electrical resistance in relaxation than in tension, and general contracture differed more from

general relaxation than did local contracture. These facts are supported by a comparison of general muscular relaxation with general muscular contraction, localized muscular contraction, and bodily conditions during silent multiplication.—*From author's summary.*

7070. WÖHLISCH, EDGAR. Besteht die Säuretheorie der Muskelkontraktion zu Recht? *Verhandl. Phys.-Med. Ges. Würzburg* 52(2): 90-96. 1927.—The author starts with the supposition that there may be 2 processes involved in the contraction, rigor and contracture of muscle; one the action of acid on collagen fibers in muscle, the other a true contraction. Although the temperature coefficient for isometric contraction is known to be negative, it is found for acid-contracture to be positive, in muscle as also in collagen. A muscle subjected to heat or chloroform finally loses its contractile power. Likewise a muscle after the resolution of rigor no longer contracts to heat or chloroform. Such muscles still shorten in lactic acid, with the same tension as in the fresh state; so that the effect is upon some resistant substance, probably collagen. A reagent like chloroform, penetrating a muscle and acting on contractile fibers, should lead to a nearly uniform rate of increase in tension. If acid acts on collagenous material, which forms mainly the external muscle sheath, it should give an early and abrupt increase, followed by a more gradual rise in tension. Results of isometric measurements, using chloroform and lactic acid, bear out these assumptions. In contrast to acid-contracture, moreover, death-rigor has a negative temperature coefficient for isometric tension, thus resembling true contraction and the second phase of chloroform-contracture.—*H. S. Hopkins.*

Med.* 57(3/4): 381-387. 1929.—Epinephrine is notable among substances which lower surface tension, particularly at surfaces where 2 fluid phases like water and oil meet. This characteristic of epinephrine produces on the isolated frog heart a positive chronotropic effect due to an increased concentration of Ca ions produced by a decrease in the surface tension of the excited tissues.

7072. BARCO, PAOLO. Modificazioni dell'equilibrio acido-basico in rapporto alla narcosi narcilenica. [Modifications of the acid-base equilibrium after narcilene anesthesia.] *Arch. Ital. Chir.* 25(6): 652-666. 1930.—From study of 25 clinical cases Barco concludes that the acid-base equilibrium after operation under narcilene anesthesia generally inclines toward acidity, from such causes as the nature of the anesthetic and the operative trauma. This disturbance of acid-base equilibrium, though marked, was slighter in degree than that observed by other authors after chloroform and ether anesthesia.

7073. BARONI, BENIGNO. Sulle alterazioni locali determinate de ipodermoclisi adrenalinizzate. [Local changes following injection of adrenalinized salt solution. [French, English and German summaries.] *Riv. Med.* [*Napoli*] 6(18): 429-431. 1929.—Experiments on guinea pigs indicated that necrosis at the site of injection of adrenalinized solutions was connected with the dose of adrenalin. This reaction was more often produced in guinea pigs by adrenalin in NaCl solution and in man by a solution in glucose.

7074. BICH, ALESSANDRO. Studii sperimentali sulle anestesie. II. L'influenza dell'anestesia generale eterea e dell'anestesia locale novocainica sulla riserva alcalina, sull'azotemia e sulla cloruremia. [Anesthesia. II. The effect of ether and novocain anesthesia on the alkaline reserve, azotemia and chloridemia.] *Arch. Ital. Chir.* 25(6): 691-699. 3 fig. 1930.—Ether was used on 7 dogs and novocain on 5. Under prolonged ether anesthesia (1-1¼ hrs.) the alkaline reserve fell, remaining low for about 6 hrs., and becoming normal within 24-48 hrs., while the blood N and chlorides first rose, then fell to normal. Under local novocain anesthesia the chlorides rose, the N generally rose, but sometimes fell, while the alkaline reserve was unchanged. The curves of the concentration of chlorides in the plasma and in the total blood declined together to a certain point from which the plasma chloride curve continued downward while the curve of the total blood chlorides began to rise along with the rise in alkaline reserve. These facts point toward some such regulatory mechanism for the blood as that suggested by Blum, who believes that increase in the concentration of CO_2 in the blood favors the passage of Cl from the plasma into the blood corpuscles, which in return yield up Na, thereby increasing the alkalinity of the plasma.

7075. BISCHOFF, GEORG. Nebenschilddrüssenhormon und Ergosterinhypercalcämie. *Hoppe-Seylers Zeitschr. Physiol. Chem.* 188(6): 247-250. 1930.—In dogs given hypercalcemia through overdoses of vitamin D (Vigantol), parathormone (Collip) produces a short initial rise in serum Ca followed by a lasting fall. About 12 hrs. after the beginning of the fall, a compensatory rise begins. It may exceed the initial Ca figure. If the hypercalcemia is moderate the serum Ca fall is of value, but if extreme, the result may be fatal.—*G. Bischoff (transl. by A. L. Hintze).*

Gynäkol.* 138(3): 782-792. 8 fig. 1929.—I subc. in 8 sexually mature female rabbits caused destructive changes, the degree of change depending less on the dosage than on the duration of treatment. The iodized rabbits failed to become pregnant. No such changes were produced by subc. injection of a protein preparation (lactosan) into 2 controls. In 5 out of 6 mice the cyclic changes of the vaginal mucosa ceased on injection of I.

7077. BUSCH, MAX. Der Ablauf der Meerschweinchentuberkulose unter Eosinwirkung. Ein Beitrag zur Frage der Heilbehandlung der Tuberkulose. *Centralbl. Bakteriol. Abt. I. (Orig.)* 114(4/6): 446-470. 15 fig. 1929.—The findings of Löwenstadt and Lange, that tuberculous guinea-pigs may be so sensitized to light by treatment with eosin as to have the course of the disease shortened, have been investigated. Using 2 controls, 9 guinea-pigs treated with eosin from the day of infection, and 5 animals treated with eosin 7 days after infection, negative results were obtained. There were no noteworthy differences between the untreated animals and those subjected to eosin treatment, whether early or late; all displayed "progressive tuberculosis."

7078. CANTONI, OSCAR. Ricerche farmacologiche sulla Nevralteina. [Pharmacological studies on neuralthein.] *Minerva Med.* 9(37): 422-426. 1929.—Studies are reported on the action on arterial pressure and respiration of neuralthein intraven. in spinal or chloralosed dogs. With therapeutic doses the action is favorable, especially if compared with acetylsalicylic acid under the same conditions. The toxicity is low, the lethal dose being 4-5 gm. per kgm.—*O. Cantoni.*

7079. CASTEX, MARIANO R., y R. LÓPEZ RAMÍ-

REZ. El cloruro de bario por via endovenosa en los bloqueos experimentales y clínicos. [Intravenous injection of $BaCl_2$ in experimental and clinical heart block.] *Prensa Méd. Argentina* 16(24): 1145-1150. 20 fig. 1930.—$BaCl_2$ (.5 to 1%) usually had no effect on auriculo-ventricular block of the toad's heart. Only in 2 toads out of 18 was the heart automatism restored by $BaCl_2$ after block. Dogs with heart block produced by nerve section were given from .01-5.5 gm. of $BaCl_2$, which slowed the auricular frequency and increased the ventricular. Extrasystoles were frequently recorded on the electrocardiograph. Clinical application of $BaCl_2$ in patients with Morgagni-Adams-Stokes syndrome showed that it was not a suitable drug to use in auriculo-ventricular heart block.

7080. CHAHOVITCH, X., et MLLE. M. VICHNJITCH. Action du chlorhydrate de morphine, de la caféine et de la quinine-uréthane sur le métabolisme énergétique. (Le métabolisme de base et le métabolisme de sommet.) *Jour. Physiol. et Pathol. Gen.* 26(3): 389-391. 1928.—It is concluded from exps. on rats that morphine and caffeine each cause an increase in the basal metabolism but a decreased total metabolism, while quinine-urethane produces a mild increase in the basal metabolism (in small doses without influence) and a decrease in total metabolism.—*H. S. Wells.*

7081. De KOCK, GILLES. Pathology of phenol poisoning in sheep induced by certain dips. *Union So. Africa Dept. Agric. 15th Ann. Rept. Dir. Vet. Serv.* 2(5/9): 643-652. 4 fig. 1929.—Phenol poisoning in sheep induced by certain proprietary dips was characterized post-mortem by a general venous hyperemia, hydropericardium, hydrothorax, emphysema of lungs, mediastinum, peritracheal region, tissues of cervical region, subcutis, edema of mucosa and larynx, sometimes of pharynx and trachea; hyperemia of lungs and mucosa of bronchi; sometimes this was complicated with small hemorrhages. Besides hyperemic and degenerative changes in certain parenchymatous organs, the lungs revealed characteristic changes microscopically, viz., extensive hyperemia and cubical transformation of the epithelial lining of the alveoli, which was in part shed, probably as a result of the accumulation of gas between epithelium and connective tissue. The question as to whether alveolar epithelium plays a part in the elimination of phenol is discussed.—*Author's conclusions.*

7082. DELBET, PIERRE. Sels halogénés de magnésium et cancers. *Presse Méd.* 36(93): 1473-1477. 11 fig. 1928.—Halogen salts of Mg are beneficial in precancerous conditions. Cancer grafts made on animals fed on a diet which included these Mg salts showed definitely smaller growths than grafts on control animals. Grafts made from growths of Mg-treated animals were in some way modified and tended to die. Gravel placed in gall bladders of control animals caused definite cancerous conditions while Mg-treated animals were entirely free from growths.—*A. M. Woodruff.*

7083. DEMOLE, V., et A. CHRIST. Guérison de la tétanie parathyréoprive du chien au moyen de l'ergostérol irradié. *Bruxelles Méd.* 10(12): 321-323. 1930.—Technique and results are outlined but no individual exps. are reported, nor is number of exps. stated. The parathyroidectomized controls died in 3-7 days with the usual symptoms. The ingestion of sufficient doses of irradiated ergosterol maintained the blood Ca at normal level and prevented untoward symptoms; insufficient doses retarded the fall of blood Ca and the appearance of fatal tetany. The administration of efficacious doses of irradiated ergosterol, with or without parathyroid hormone, kept parathyroidectomized dogs in good health for months.

7084. EDMUNDS, CHARLES W., HAROLD W. LOVELL, and SPENCER BRADEN. Studies in bioassays: "The proposed international standard for digitalis." *Jour. Amer. Pharmaceut. Assoc.* 18(8): 778-784. 1929.—The powdered digitalis which is proposed as an International standard is about 30% stronger than the U. S. P. X standard. With the strophanthins and with the tinctures of strophanthus, a dose 10% larger is necessary to cause systolic standstill of the frog's heart in 4 hrs. when it is given into the lymph sac than when the drug is given intravenously and 1 hr. allowed for observation. A dose of the strophanthins 40-50% larger is required in the 1-hr. lymph sac method than in the 1-hr. intravenous method. For tinctures of strophanthus the dose, when it is given into the lymph sac and one hour allowed for observation, must be almost double the intravenous dose. For tinctures of digitalis, the dose, whether for a 1-hour or for a 4-hour period of observation, must be about 65% above the intravenous dose, indicating greater ease of absorption of digitalis from the lymph sac as compared with strophanthus, as absorption is practically complete in 1 hr.—*Authors' abstract.*

7085. EICHHOLTZ, FRITZ. System biologischer Schwermetallreagenzien. *Arch. Exp. Pathol. u. Pharmakol.* 148(5/6): 369-376. 1930.—The metabolic functioning of the living cell is partly dependent on the action of heavy metals. Thus, for example, glycolysis in carcinoma cells is considered to be a Cu catalysis, and the Pasteur reaction an iron (ferro) catalysis. For the determination of such heavy metal catalyses in living cells, non-poisonous substances which can form complexes with heavy metals are needed, possessing specific affinity to each particular heavy metal. The paper lists a provisional system of such heavy metal complex formers, collected for the purpose of discovering further cases of biological heavy metal catalysis.—*F. Eichholtz (transl. by C. S. Leonard).*

7086. EIGENBERGER, F. Some clinical observations on the action of Mamba venom. *Bull. Antivenin Inst. America* 2(2): 45-46. 1928.—An intradermal injection of diluted Mamba venom is followed by burning sensation, local itching and swelling, sensorial irritability, weakness and various nervous symptoms; about 5 or 6 hrs. later, pain is felt over all the body especially in the cranial nerve fields, gradually decreasing until the next day when only a little discomfort in the tongue and esophagus with some swelling at the site of the injection are all that remain of the effects of the venom. This type of poisoning seems to be due to an effect on the central nervous system, particularly marked on the subcortical centers.—*A. do Amaral.*

7087. EWSEROWA, E. K. Das Nervensystem der Hunde bei experimenteller Bleivergiftung. *Arch. Psychiatr. u. Nervenkrank.* 88(5): 752-775. 8 fig. 1929.—Length of life and severity of symptoms bore no direct relation to each other in experiments on 5 dogs. The clinical manifestations were (a) psychic, (b) convulsive, of general and cortical type, (c) paresis and ataxia, and (d) emaciation, exhaustion and sometimes marked cachexia. The pathologic-anatomic changes were of various types: (a) diffuse degenerative processes in the visceral and somatic centers of the brain and spinal cord with predominant localization sometimes in the deep cortical layers, sometimes in the tuber cinereum, (b) cell proliferation, formation of foci in the vascular walls, and (c) in one case a focus in nerve tissue. The psychic changes, the convulsions, the pareses and the ataxia were due to a diffuse degenerative process in the brain, particularly the cortex. The lesion of the nucleus of the tuber cinereum might possibly be the cause of the disturbance of metabolism, the exhaustion and cachexia, but this was not the sole causal factor in this series of animals. The pathologic-anatomic processes in this series of dogs differs from those observed by other authors in cats, through lack of the ameboid reaction and presence of mesodermal proliferative changes.

7088. FALKENHAUSEN, M. Die Wirkung der experimentellen Phosphorvergiftung auf die Verdauungsfermente des Blutes. *Arch. Exp. Path. u. Pharm.* 132(1/2): 106-117. 1928.—P poisoning is followed by an extraordinary increase in the diastatic action of blood serum. This is not due to a change in activation or to an accumulation of diastase which might result from disturbed excretion in the urine, or to the effect of a transfer of bile to the bloodstream. The pancreas is not the seat

of increased diastase production, because the increase following P poisoning also occurs in depancreatized dogs. The liver is the probable seat of this increase. A change in the proteolytic capacity of serum towards carmine fibrin could not be demonstrated. The lipolytic capacity of serum is remarkably decreased by P poisoning even following the extirpation of the pancreas. This effect offers no explanation of the origin of blood lipase.—*J. M. Johlin.*

7089. FREINSCHMIDT, O., und D. FERDMANN. Die Einwirkung von Adrenalin auf den Kreatinphosphorsäuregehalt der Muskeln. *Biochem. Zeitschr.* 205(4/6): 325-328. 1929.—Phosphocreatine and inorganic phosphates were determined according to the authors' modifications of the Fiske-Subbarow method. Epinephrine (0.6-0.7 mgm.) was injected into the pectoral muscle of pigeons and the same muscle was analyzed 45 to 110 min. after injection. In 5 uninjected controls the inorganic P was on an average 45 and the phosphocreatine-P 32 mgm. %. After epinephrine injection into 7 pigeons the corresponding values were 81 and 12 mgm. % resp. The conclusion is that epinephrine splits phosphocreatine. After 2 hours hydrolysis in 2% $NaHCO_3$ the muscle of the injected pigeons contained more inorganic P than that of the controls. In 2 controls the average lactic acid content of the muscle was 143, in 4 animals injected with epinephrine it was 272 mgm. %.—*G. T. Cori.*

7090. GIACOMINI, ERCOLE. Sulla presenza, distribuzione e vie di eliminazione dell'ormone tiroideo (tiroxina) nell'ipertiroidismo sperimentale ed osservazioni analoghe sul comportamento dell'adrenalina e di altri ormoni. (Ricerche chimiche e biologiche comparative su uccelli, mammiferi, girini e axolotl). [Presence, distribution and elimination of the thyroid hormone (thyroxin) in experimental hyperthyroidism and analogous observations on the behavior of epinephrine and other hormones (chemical and biological studies on birds, mammals, tadpoles and axolotl.)] *Rend. Sess. R. Accad. Sci. Ist. Bologna Cl. Sci. Fis.* 32: 22-52. 1927-28(1928).—Metamorphosis of the axolotl, *Amblystoma tigrinum,* and of the tadpoles of *Rana, Hyla* or *Bufo* is induced by giving the fresh or powdered organs (liver, kidneys, spleen and desiccated blood, urine and bile) of animals (guinea pigs, dogs, chickens) previously hyperthyroidized by large doses of fresh or dried bovine thyroid. Thus a part of the thyroid hormone, thyroxin, is recovered in the organs (e.g., bile) of the the hyperthyroidized animals and in their excreta (urine) in which there is an increase of I content. Similarly for epinephrine after large doses of fresh or dried adrenal medulla, and of fat bodies, after large doses of adrenal cortex. Hormone elimination is one of the means of regulating the hormone content in blood when present in excess thus aiding in maintaining the hormonic equilibrium of the blood.—*E. Giacomini (transl. by J. G. Edwards).*

7091. GILBERT, N. C., and G. K. FENN. The effect of the purine base diuretics on the coronary flow. *Arch. Internal Med.* 44(1): 118-127. 2 fig. 1929.—Experiments on dogs indicated a vasodilator effect from purine base diuretics on the coronary arteries, as shown by an increased return flow through the coronary sinus, the order of efficacy being: theobromine and salts (71 exps.); theophylline ethylenediamine (23 exps.); theophylline sodium acetate (11 exps.), and caffeine (12 exps.).

7092. GRUBER, CHARLES M. The peristaltic and anti-peristaltic movements in excised ureters as affected by drugs. *Jour. Urology* 20(1): 27-59. 13 fig. 1928.—A perfect metabolic gradient from kidney to urinary bladder was not observed in the excised ureter of the pig. It was normally highest in the kidney end, gradually decreasing until the lowest 4th was reached where it suddenly increased again to an irritability almost as great as that in the kidney end. Spontaneous peristaltic contractions were noted in the kidney half of the ureter in 73.6% of the segments tested and in only 28.1% of the segments of the bladder half of the ureter. Spontaneous antiperistaltic contractions were observed in the kidney half of the excised ureter in 26.3% of the cases but in the bladder half of the ureter this reverse movement was found in 71.9% of the segments. Spontaneous antiperistaltic movements as well as peristaltic movements were noted when the whole excised ureter was used. Fluids placed in the lumen of the ureter were propelled from the kidney end toward the bladder end during peristalsis and in the reverse direction during antiperistalsis. A relative refractory phase was also noted to stimulation. Decreasing the temp. of the "pace maker" from 39.5 to 22° C. causes slowing of contraction and in some cases complete inhibition. If the temperature of the fluid surrounding the dependent segment is maintained at the optimum temp. 39.5° C., a reversal of the direction of contraction is frequently seen, i.e., antiperistalsis is converted into peristalsis and vice versa. Decreasing the pH of the solution bathing the dependent segment from 7.8 to 5.6 has little or no effect upon its contractions, on the contrary decreasing the pH of the solution bathing the "pace maker" caused temporarily complete inhibition of activity of both segments. If the pH of the dependent segment is maintained at 7.8 to 8.8 reversal of movements is noted. Epinephrine added to the solution bathing the dependent segment stimulated it and reversed the direction of conduction and peristaltic movements were thus converted into antiperistaltic contractions and vice versa. Urea, acetylcholine and nicotine caused changes similar to those caused by epinephrine, though in most instances less marked.—*C. M. Gruber.*

Kreislaufforsch.* 21(22): 673-676. 4 fig. 1929.—Isoamyl alcohol lowers the blood pressure and dilates the blood vessels. Ethyl alcohol at low concentration dilates the peripheral blood vessels, and at high concentration constricts them.

7094. HEYMANS, C., et P. REGNIERS. Influence de l'ergotamine sur les réflexes cardio-vasculaires du sinus carotidien. *Arch. Internat. Pharmacodyn. et Thér.* 36(1): 116-121. 1929.—Ergotamine reinforces the cardio-inhibitor reflexes of the carotid sinus; this action is due as Rothlin has shown to the fact that ergotamine sensitizes the cardio-parasympathetic. This hyperexcitability persists only from 10 to 15 min. after injection. Ergotamine suppresses all the vaso-regulating reflexes from the carotid sinus. To admit the theory of Dale on the subject of paralysis of the vaso-constrictors and not of the vaso-dilators one must conclude that the vaso-regulating reflexes are due solely to some modification of tonus of the vaso-constrictors. If vaso-dilators intervene in the vascular reflexes of sinus origin they ought to persist in effect (Dale) and even be reinforced (Rothlin) after the injection of ergotamine. Ergotamine suppresses equally the epinephrine reflex of the vaso-motor tone of sinus origin. Ergotamine does not act upon the vaso-sensitive terminations of the carotid sinus but upon the other peripheral or central elements of cardio-vascular and suprarenal reflexes.—*C. Heymans (transl. by L. B. Nice).*

Infektionskrankh.* 109(2): 266-271. 1 fig. 1928.—The method of analysis has been previously reported. It is readily applicable whether the car is standing or moving. The efficiency of a patent safety apparatus for diluting the fumes with atmospheric air before disposal was studied. The toxic gases were found to be diluted by this apparatus from 10 to 15 times.—*H. S. Wells.*

7096. HIRSCHFELDER, ARTHUR D. Antagonization of the narcotic action of magnesium salts by potassium, sodium and other monovalent cations, with a contribution to the theory of narcosis and analgesia. *Jour. Pharmacol. & Exp. Therap.* 37(4): 399-412. 1929.—Rabbits narcotized with $MgSO_4$ can be awakened by the injection of KCl as completely and as suddenly as by $CaCl_2$. RbCl, NaCl and CsCl produce the same effect. The

order of ionic effectiveness is K > Rb > Cs > Na > Li. This order of effectiveness does not follow the order of either atomic weight, distribution of electrons or ionic hydration. The antagonism of monovalent cations to Mg, like that of Ca, can be explained by Clowes' theory of the existence of a balanced mixture of water-in-oil and oil-in-water emulsions in the surface layer of the cells, though most of the facts can also be explained by the existence of a continuous layer of lipids, especially of phosphatids, as claimed by Koch, Hansteen-Cranner, Lillie and MacDougall. The predominance of water-in-oil emulsions or of dehydration of the phosphatids seems to associate the "anesthetic and analgesic phase" with the surface layer of the nerve cells. The same phenomena of alteration in the balance of emulsions is also encountered in the effects on emulsions induced by volatile anesthetic, soporific and analgesic drugs, which are non-alkaloidal in nature; and are substantiated by the synergism of analgesic with narcotic drugs, and of Mg salts with cinchophen. These purely physical effects seem to furnish a clearer picture for the explanation of the action of these drugs than is furnished by their effects upon blood dilution.—*Author's summary and conclusions.*

7097. **HOLBØLL, S. A. Untersuchungen über die Ausscheidungsverhältnisse von Phenolsulfonphthalein und Natriumthiosulfat bei Personen mit gesunden Nieren.** *Zeitschr. Klin. Med.* 111(1): 117-127. 1929.—The excretion of phenolsulphonephthalein and $Na_2S_2O_3$ injected intraven. was investigated in 5 normal individuals. Injections were made in varying doses but always together in the constant ratio of 6 mgm. phenolsulphonephthalein to 1 gm. $Na_2S_2O_3$. About 80% of the phenolsulphonephthalein was excreted through the kidneys independent of the amount of the dose. The proportion of $Na_2S_2O_3$ excreted, however, was closely dependent on the dose employed. This indicates that an important distinction between the 2 functional tests consists in the fact that $Na_2S_2O_3$ is very easily oxidized in the organism. The urine was collected at intervals of 20 min.; it was apparent that the largest amounts were excreted in the first 20 min. after injection.—*From author's summary (transl.).*

7098. **HOLZBACH, KOTTLORS, und IRION. Orasthin und Tonephin, zwei Fraktionsprodukte des Hypophysins.** *Zentralbl. Gynäkol.* 54(2): 90-97. 1930.—Orasthine contracts muscle strongly, increases muscle tonus, and acts on the uterus, but not on blood pressure. Tonephine does not affect the uterus. In strong concentrations it contracts muscle. It acts on blood pressure like the whole extract, hypophysin. Tonephine's chief action is its intense effect on intestinal peristalsis. It also produces water retention in the tissues.

7101. **HUGHES, T. A., and D. L. SHRIVASTAVA. Studies on the enlarged malarial spleen. I. Effect of adrenalin on the blood picture. II. Effects of intravenous and oral administration of quinine on the blood picture.** *Indian Jour. Med. Res.* 17(3): 651-655. (ibid.) 657-665. 1930.—I. Observations were made on the changes in the blood picture brought about by contraction of the enlarged spleen in chronic malarial patients following the subc. injection of 1 cc. adrenalin sol. (1:1000). In some patients of this type contraction of the spleen causes little or no increase in the circulating red cells, especially in the absence of an acute condition. A leucocytosis always followed injection of adrenalin, the most marked change in quiescent cases being an increase in the monocytes and large lymphocytes. II. A study was made of the changes in the blood picture in chronic malarial patients with enlarged spleens following the administration of quinine (a) by the intravenous, and (b) by the oral route. (a) Intravenous injection of 6 grains of quinine HCl in 10 cc. saline brought about the following changes:—1. An increase in the leucocytes, especially the large lymphocytes and monocytes. This is similar to the leucocytosis that follows injection of adrenalin in such subjects. 2. A fall in the red cells succeeded by a return to normal or a slight increase. There was also a delayed increase in the bilirubin content of the plasma. Reasons are given for considering this to be an indication of hemolysis. It did not occur in control experiments on normal subjects. (b) Blood counts made at intervals of 24 hrs. on patients having 10 grains of quinine HCl by mouth 4 times a day revealed the following changes:—1. A rise in the leucocytes always affecting the monocytes. 2. A small rise in the red cells. When quinine in these doses was combined with alkalies there was a sharp rise in both white and red cells reaching a maximum about the 2nd day. The granulocytes often took a prominent part in the leucocytosis.—*Authors' conclusions.*

7102. **HUTCHISON, R. H. On the incidence of snake-bite poisoning in the United States and the results of the newer methods of treatment.** *Bull. Antivenin Inst. America* 3(2): 43-57. 1929.—According to statistics based on 607 cases of snake bite reported within the Continental U. S. A. during 1928, 451 of which were definitely assigned by species, 171 were caused by the copperhead (*Agkistrodon mokasen*) and 100 by the Texas rattler (*Crotalus atrox*), these two making up about ½ the total. Among the states, Texas contributed 163, Alabama 49, and Pennsylvania 42. Most of the victims were adult males; the regions most often bitten were the feet, the fingers, the shins, the ankles, the hands, etc. The mortality among the cases treated without antivenin was 10.8%, whilst that among the antivenin treated cases was 3%. A complete description is given of the therapeutic measures indicated to combat snake poisoning.—*A. do Amaral.*

7103. **ISHII, RAIUI and SHINZO SAKATA. Über den Synergismus zwischen dem Adrenalin und dem Cocain bei der Zuckermobilisierung der Krötenleber.** [Orig. in Japanese p. 158-183.] *Folia Pharmacol. Japonica (Breviaria)* 8(3): 4. 1930.—The sugar content of the perfusion fluid of surviving toad livers was analyzed by the Hagedorn method. Cocaine 1:300,000 mobilized no sugar, cocaine 1:100,000 was slightly effective. Previous perfusion of the liver with cocaine always increased the action of epinephrine on sugar mobilization.—*Author's summary (transl. by G. T. Cori).*

7104. **JUNG, GEORG. Tierexperimentelle Untersuchungen zur medikamentösen Therapie der eitrigen Meningitis.** *Zeitschr. Hals-, Nasen- u. Ohrenheilk.* 25(1): 32-62. 1929.—Experiments were made on the therapeutic effect of hexamethylenamine on *Staphylococcus aureus* (*hemolyticus*) infection of the rabbit's brain. Of 8 rabbits injected intraven. with hexamethylenamine at the same time they were infected with the staphylococcus, only 1 survived. Of 23 rabbits injected previously, then infected, and subsequently treated with hexamethylenamine, 13 survived; but of the 10 that died 3 succumbed apparently to other causes than meningitis. Other studies were made on the organic injury inflicted by hexamethylenamine. Exps. on 2 rabbits showed that injection of 2 gm. or even 1.2 gm. of hexamethylenamine per kgm. in 40% sol. caused a 60% drop in blood pressure. Exps. on 2 other rabbits showed that the same dose in 20% and 10% sol., resp., caused practically no fall in blood pressure. Exps. in vitro showed that hexamethylenamine

is somewhat hemolytic to both human and rabbit blood. No special injury to kidneys and bladder from hexamethylenamine, intraven., in amounts from 2 to 29 gm. per kgm., was found in 14 rabbits. This might be attributed to the fact that in the rabbit, an exclusively herbivorous animal, the urine is alkaline, so that no formaldehyde irritation can result. To produce acid urine, 2 rabbits were fed exclusively on oats and milk. In one, given intraven. doses of hexamethylenamine, very slight injury to the urinary tract appeared; in the other, given what corresponds to therapeutic doses, none at all. In 2 dogs, given heavy doses of hexamethylenamine by mouth, one with and one without $NaHCO_3$, no great difference in the bladder and kidney changes were observed. No prophylactic, therapeutic or injurious effect was observed from trypaflavine, given to 6 rabbits. Rivanol, given to 13 rabbits, had a certain favorable therapeutic influence, less prophylactic effect than hexamethylenamine, and no injurious effect.

7105. KELLAWAY, C. H., and F. ELEANOR WILLIAMS. The venoms of Oxyuranus maclennani and of Pseudechis scutellatus. *Australian Jour. Exp. Biol. and Med. Sci.* 6(3): 154-174. 5 fig. 1929.—Three samples of snake venom have been investigated, 2 unquestionably from *Oxyuranus maclennani* Kinghorn, and 1 which is almost certainly the venom of *Pseudechis scutellatus* Peters. The venom of *Oxyuranus* injected subc. is lethal to monkeys in doses of the order of 1.0 mgm. per kgm., to rabbits in those of 0.5 mgm. per kgm., to guinea-pigs in those of 0.08 mgm. per kgm., and to rats in those of 0.6 mgm. per kgm. Injected intraven. it is lethal to rabbits in doses of the order of 0.1 mgm. per kgm. The venom contains "thrombase," and causes intravascular coagulation in sufficient dosage. It coagulates citrated plasma *in vitro*. It is only feebly hemolytic, but is powerfully neurotoxic, death in most animals being due to this activity of the venom. It has a slight immediate depressor effect on the blood pressure, and finally causes death by respiratory failure. It diminishes the output of the heart. The venom presumed to be that of *Pseudechis scutellatus* injected subc. is lethal to rabbits in doses of the order of 2-3 mgm. per kgm., to guinea pigs in doses of from 1.5-2.0 mgm. per kgm., and to rats in doses of 4-8 mgm. per kgm. Injected intraven. in rabbits it kills in doses of about 0.7 mgm. per kgm. The venom has powerful anticoagulant and hemolytic activities, but is only feebly neurotoxic. Its effects on the circulation in rabbits are in the main secondary to its hemolytic action. Both these venoms have a stimulant action on isolated plain muscle.—*Authors' conclusions.*

7106. KIM, SANGTAE. Über die pharmakologische Wirkung des ätherischen Öls von Atractylis ovata Thunb. [Japanese] *Chosen Igaku Kwai Zasshi* 83: 1008-1018. 1927.—The volatile oil prepared by Ichika Yamaguchi from the rhizome of *A. ovata*, a drug which is employed in Chinese medicine in various diseases, was studied on animals. It produces in frogs a central depression of respiration, general motor paralysis, and finally cessation of respiration. In mice, there are increased reflex activity, sweating and convulsive attacks. Respiration becomes more frequent and dyspneic, then slower, weaker and finally stops. In rabbits light motor paralysis of the extremities and transient increase in respiration occur. The blood pressure is lowered. These effects are due primarily to central depression, but also in part to heart weakness and peripheral vaso-paresis. Later, respiration is paralyzed by large doses. The frog's heart, isolated or in situ, is depressed and finally arrested in diastole, probably by direct effect upon the heart muscle. The blood vessels of frog's muscles are dilated. In organs with smooth muscle the poison acts chiefly upon the muscle. The tone of the rabbit's intestine and uterus is depressed and the pendulum movements are weakened. Skeletal muscles and motor nerves are but little affected by the oil.—*Author (courtesy Japanese Jour. Med. Sci. IV) (transl. by B. Fantus).*

7107. KINDT, BRUNO, und HUBERT VOLLMER. Untersuchungen über pharmakologische Eigenschaften des β-Naphthochinolins und einiger seiner Abkömmlinge. *Arch. Exp. Pathol. u. Pharmakol.* 148(3/4): 198-210. 1930.—β-naphthoquinolin and its derivatives had an [injurious] action on both the gastrocnemius of the frog, and the animal as a whole. This series also exerted a central toxic action on the nervous system. Phenantrolin was least active. Naphthoquinolin caused marked lowering of temp. in mammals without fever. In both frogs and mammals poisoned by naphthoquinolin derivatives there was hemorrhage of the internal organs and fatty degeneration of the liver. Cardiac action of naphthoquinolin and its several derivatives was much alike. The heart beats increased in frequency, then the heart no longer responded to stimuli, and finally came to a systolic standstill. The toxicity of these drugs for the whole animal can be placed in series as follows: Naphthoquinolin > nitroaminonaphthoquinolin > mono- and diaminonaphthoquinolin. The amino compounds had a stronger antiputrefactive action than the others. Phenantrolin is about as toxic, but inhibited putrefaction somewhat less than did naphthoquinolin.

7108. KLEIN, O., und M. KMENT. Beobachtungen über Insulin-Hypoglykämie beim Menschen. III. Verhalten der Eiweissfraktionen des Blutes, des Bilirubins, der Blutkonzentration und der Blutgerinnung, insbesondere bei Leberkranken. *Zeitschr. Klin. Med.* 107(5): 476-487. 1928.—The following observations were made in liver disease when insulin shock was induced. There was generally lowering of the bilirubin content, shortening of the coagulation time and an increase in the total serum albumin. There was an absolute and often also a relative increase in the fibrinogen and globulin fractions. After long-continued administration of insulin in high dosage there develops hydremia with increase in relative amount of fibrinogen and globulin fractions and also increase in the volume of the individual red cells but in the earlier stages of insulin shock there is definite concentration of the blood with decrease in the volume of the individual red cell and decrease in plasma volume. Earlier observations of the association of water metabolism with insulin effect are thus confirmed.—*R. G. Stillman.*

7109. KOCHMANN, M. Prüfung von Ovarialpräparaten des Handels. *Arch. Exp. Pathol. und Pharmakol.* 137(3/4): 187-200. 1928.—The pseudo-oestrus producing efficiency of 7 ovarian preparations was studied by injecting various dosages into spayed mice. Determined activity: Hormovar and Succototal 4 to 5 units per ccm. (as claimed by label); Sistomensin 1 unit per ccm. (no standard claimed); Menoformon, of two preparations tested, one showed an activity of 20 to 26 units per ccm. and the other an activity of 8 to 10 units per ccm. although both preparations were labeled as 40 units per ccm. Panhormon showed an activity of 2 instead of 20 units per ccm. as claimed. Agomensin was ineffective. The influence of these preparations on metabolism (O consumption and CO_2 production) was also noted. Following injection of ¼ to ½ of a rat unit of menoformon, hormovar, succototal and panhormon, an increased O consumption of greater or less degree occurred. Sistomensin and the remaining preparations were ineffective. Following oral administration, Oophorin and dried ovary are not tolerated by rats. Ovowop depressed O consumption without affecting body weight. Ovaradin was well tolerated and when fed over a 4 week period depressed metabolism slightly; during the succeeding 6 weeks, a slight but insignificant rise occurred. —*O. W. Barlow.*

7110. KOHLHOFF, HEINZ. Experimentelle Untersuchungen über Coramin. *Arch. Exp. Pathol. und Pharmakol.* 136(5/6): 331-348. 1928.—Coramin stimulates all reflexes (position and movements) of rabbits. Respiration is deepened and accelerated. During convulsions the position reflexes are paralysed but rapidly return on cessation of the convulsion. The effects of coramin develop rapidly after intraven., subc., or oral administration. The rapid development of the effects after oral administration suggests absorption from the stomach.

Coramin convulsions may be as effectively produced after removal of the fore- and mid-brain as in a normal animal. Spinal animals show tonic convulsions and running movements after its administration. The convulsant actions of coramin may be antagonized by paraldehyde or chloral. With light grades of hypnosis, coramin injections produce a temporary recovery, but permanent recovery can not be produced by successive injections at short intervals.—*O. W. Barlow.*

7111. **KOTELNIKOW, K. I. Charakter und Wirkungsmechanismus kleiner Mengen von Salzen und des Truneček-Serums.** *Zeitschr. Ges. Exp. Med.* 69(3/4): 297-320. 1930.—Therapeutic literature abounds in accounts of "wonderful" cures by injection of NaCl, $CaCl_2$, KI, $MgSO_4$, Lugol's solution and Truneček's serum. The undeniable effect of these substances on the acid-base equilibrium has never been explained. To determine the changes produced by acid, neutral and alkaline salts and by Truneček's serum, and to try to find an explanation for these changes, a series of studies (number not stated) was carried out. The curve of variations in CO_2 tension in a patient was studied for several control days without injection of any kind of treatment, and then after subc. injection of Truneček's serum; and similarly for sols. of single salts. The following conclusions were reached: The effect of these small quantities (5, 15 and 25 mgm.) of inorganic salts and of Truneček serum on the acid-base equilibrium is unmistakably expressed in changes in the CO_2 tension of the alveolar air. Strongly alkaline salts, subc. employed, decrease the CO_2 tension; acid salts in most cases increase it; neutral salts produce variable changes, now increasing, now decreasing the tension. K salts are more active than the corresponding Na salts of the same anions. There are 3 possible ways in which these substances may affect the organism: by immediate action on the cells, by indirect effect on the cells through the vegetative centers reached by the blood, or by stimulation of the peripheral nerve endings transmitted to the vegetative centers. The last view is favored. The vegetative reaction to acid and alkaline salts parenterally introduced is paradoxical, the acid salts increasing the alkaline valences in the blood and the alkaline salts increasing the acid reaction. The reactions are not proportioned to the amounts of acid-forming or alkaline substances introduced, and are thus comparable to biological reactions like immunization.—*From author's summary (transl.).*

7112. **LABBÉ, M., F. NEPVEUX, et MONZAFFER CHEVKI. Effet de l'alcool sur la glycémie et sur les échanges respiratoires chez les sujets sains et les diabétiques.** *Arch. Malad. Appar. Digestif* 19(9): 1053-1058. 1929.—Alcohol ingestion lowered blood sugar in diabetics and raised it in normal persons. From 12 to 17 gm. of alcohol was fed. The action was apparent after ½ hr. and remained for about 5 hrs. The effect of alcohol on total metabolism in diabetics was variable. In one case metabolism was increased, in 3 cases lowered, the maximum effect being observed ½ hr., 1 hr. or 2 hrs. after administration. In normal subjects basal metabolism increased. Respiratory quotient was decreased in diabetics and normal subjects by alcohol.

7115. **MANTINI, MANRICO. Il perhydrol e l'acido peracetico nella distruzione delle Sostanze Organiche in Tossicologia. [Perhydrol and peracetic acid in the destruction of organic substances in toxicological tests.]** *Riv. Biologia* 10(5/6): 623-629. 1928.—In view of the well known accelerating action of oxidizing agents in the destruction of organic substances, exps. were made on white mice and guinea pigs, boiling their viscera for a period of 2-4 hrs. in 1 part by wt. of glacial acetic acid and 6 of perhydrol. After eliminating the excess of H_2O_2 by addition of $NaNO_2$, clear and positive reactions were obtained in tests for Pb, Ba, Ag, Hg, As and Sb. This method combines rapidity with the maximum of practical results.—*M. Mantini (transl. by P. Hillkowitz).*

7116. **MARULLAZ, M. Action des sels de magnésium sur la genèse des tumeurs du goudron.** *Bull. Acad. Méd.* 103(5): 166-172. 1930.—In 2 rabbits from a previous series of experiments, to which $MgCl_2$ had been administered for 411 days, while each ear had been painted with tar for 368 days, the growths produced were benign, and the formation had become retarded. $MgCl_2$ was now administered daily from July 25, 1929, to a new series of 8 rabbits. August 1, the upper ½ of the inner surface of the right ear was painted with tar, and the treatment was repeated once a week thereafter. After 168 days, 3 of the animals presented no alteration except a beginning follicular hypertrophy of the zones treated, while proliferation of the epidermis was observed between the 60th and 90th day in 8 out of 10 controls treated with tar but no $MgCl_2$. In 5 of the $MgCl_2$-treated animals, more marked abnormal activity of the epithelium was present, but temperature, sensitiveness and consistency of the ears were normal. In 1 of 2 albinos, a benign papilloma at length underwent regression. In another a tumor formed, became detached, and fell, leaving a notch 0.5 cm. long by 3 mm. deep in the edge of the ear. To study the curative effects of $MgCl_2$, it was given to 3 rabbits in which neoplasms had been produced by tar. In all 3 an arrest of the growth was obtained in about a month after the $MgCl_2$ treatment had begun; in 2 the tumors showed a tendency to become dry.

7117. **MEYER, ERNST. Über das Muttkorninfus.** *Zeitschr. Geburtshülfe u. Gynäkol.* 95(1): 96-124. 2 fig. 1929.—Ergot preparations of various types and ages were compared with gynergen, pituitrin, etc., by the reaction of the guinea pig uterus. The reaction to an infusion of ergot varies markedly due to both biologic variability and to the relative content of the various components of the infusion. The ages of the infusions (up to 12 days) thus gave widely different results, but the method used for standardization gave no significant data which could demonstrate variations of potency with time. The effectiveness of ergot preparations is dependent on all of the infusion components and to no particular one. None of the standardization methods give results which are quite reliable either as to effectiveness or as to the nature of the reaction of the human uterus. The final and most important test of effectiveness is the reaction of the human uterus rather than that of the guinea pig.—*O. W. Barlow.*

7118. **MHASKAR, K. S., and J. F. CAIUS. A study of Indian medicinal plants. II. Gymnema sylvestre,** Br. *Indian Med. Res. Mem.* No. 16. pp. 1-49. map. 1 pl. 1930.—The air-dried leaves of *G. sylvestre** yielded, after ignition, 11.45% of inorganic matter which was found to contain in %: "alkali" 46.76; H_3PO_4 6.73; Fe_2O_3 5.44; Mn 1.31. They do not contain any water-soluble or alcohol-soluble substance which destroys glucose in vitro; nor do they yield any chemical body resembling insulin. They contain the 2 hydrocarbons hentriacontane and pentatriacontane, chlorophyll *a* and *b*, phytol, resins, tartaric acid, inositol, anthraquinone bodies, and "gymnemic acid." "Gymnemic acid" is a

highly complex mixture which may be fractionated by successive treatment with petroleum ether, ether, chloroform, ethyl acetate, and alcohol. It is evident that none of these fractions represents a homogeneous substance. The leaves of gymnemic acid have no bactericidal action in vitro. Their toxic action is manifested by loss of appetite, diarrhea and asthenia, which, in animals, is followed by paresis of the limbs, irregularly high temp., and death, usually without convulsions, due to respiratory failure. They stimulate the heart and circulatory system, increase urine secretion and activate the uterus. They cause hypoglycemia which sets in soon after the administration of the drug whether by mouth or by injection, lasts for a variable time, is not necessarily proportionate to the dose and is never excessive. The drug has no direct action on carbohydrate metabolism, and acts indirectly through stimulation of insulin secretion of the pancreas. The presence of anthraquinone derivatives accounts for the laxative action of the leaves. The drug appears to be useful in checking glycosuria when administered in doses of 2 to 4 gm. of dry leaf.—*Authors' summary.*

7119. **MIYASAKI, SABURO.** **Zur Pharmakologie des Bleies. V. Mitteilung: Die Resorption des Metalls vom Magen-Darmkanal und die Möglichkeit ihrer Beeinflussung.** *Arch. Exp. Path. u. Pharmakol.* 150(1/2): 39-46. 1 fig. 1930.—Absorption of Pb from the gastro-intestinal canal is a simple diffusion process. In a given period a certain percentage of the total Pb present will be absorbed, but this quantity is not proportional to the total amount administered. Dialyzed $Fe(OH)_3$, or milk, delayed Pb absorption. The action of milk on Pb absorption can be explained by the phosphate content of the milk, since Pb phosphate was found unable to pass through a precipitation membrane of permanganate.

7120. **MODINOS.** **Le sérum du vésicatoire dans le traitement et la prophylaxie des maladies infectieuses.** *Paris Méd.* 19(15): 349-352. 1929.—Out of an indefinite "large series" of clinical observations, 4 illustrative cases are given (1 Malta fever, 1 typhoid, 1 asthma and 1 pyodermatitis) in which vesicants were applied to the skin and injection of the serum from the blisters induced cure.

7121. **MONCORPS, CARL.** **Untersuchungen über die Pharmakologie und Pharmakodynamik von Salben und salbeninkorporierten Medikamenten. I. Über das Wasserbindungsvermögen von Salben. II. Über die Resorption und Pharmakodynamik der salbeninkorporierten Salizylsäure. III. Untersuchungen über die Resorption und Pharmakodynamik des salbeninkorporierten elementaren Schwefels. IV. Über die Beeinflussung des Schwefelhaushaltes beim Menschen nach Schwefelsalbenanwendung.** *Arch. Exp. Path. u. Pharmakol.* 141(1/2): 25-49. 10 fig.; 50-66; 67-86. 3 fig.; 87-104. 1929.—I. Pastes and salves are divided into 2 main classes, of which the larger is that in which the aqueous portion is emulsified in an oil medium (Wa_a-Ö emulsions) and the other, that in which the disperse phase is that of the oil, emulsified in a watery medium ($Ö_a$-Wa emulsions). The cooling effect of a salve depends not on the amount of the water incorporated in it but on the readiness with which the water evaporates. This is facilitated by either an $Ö_a$-Wa emulsion or a coarsely disperse, labile Wa_a-Ö emulsion. The effect of Wa_a-Ö emulsions varies according to the stability of the emulsion and the form of application; a thick layer of a stable Wa_a-Ö emulsion is like an impermeable moist dressing, while a labile Wa_a-Ö emulsion has much the effect of an $Ö_a$-Wa emulsion or of a moist permeable dressing. The different forms of emulsion create different adsorption conditions. II. A number of series of inunction experiments were carried out on 6-10 human subjects with salicylic acid in various bases; both base and method of application affected the results. Absorption, as was shown by elimination through the urine, varied within wide limits; no salicylic acid was demonstrable in the urine 6 hrs. after application. Keratolysis was markedly increased if the salve was such or so applied as to promote swelling of the stratum corneum. Salicylic acid in aqueous solution applied in the form of permeable moist dressings neither affected keratolysis nor produced a stronger absorption than alcoholic solutions. The alkali reserve of the blood was not affected by the absorption of salicylic acid incorporated in salves. III. The backs of 175 white mice were shaved, care being taken to avoid breaking the skin, over which was spread a salve containing 0.5 gm. of 10% precipitated S, the animal being kept outstretched to prevent its removing the salve. About 0.3-0.5 cc. of a 2% suspension of Bi subnitrate was then subc. injected under the salve without breaking the underlying skin (the long, slender needle being introduced in the tail and directed to a point under the skin of the back). After 5-6 hrs. a blackening of the Bi deposit (not seen in the control animals) indicated the formation of Bi_2S_3. Of the various bases, benzoinated lard produced the most rapid and intense effects, and ZnO paste the least. To determine the earliest time at which the S begins to react with the subcutaneous Bi, 20 mice were treated with S salve and injection of Bi, and killed and histologically examined at 10-min. intervals afterward. The marginal blackening of the subcutaneous deposit was found to begin 110 min. after injection at the earliest. While the result was not affected if the Bi injection was made 5-6 hrs. before the S application, it was much weakened if the Bi suspension was injected 4-5 hrs. after the application of the S salve, and nearly or quite annulled if the injection was made 12 hrs. afterward. To determine if the absorbed S could produce sulphides at a point distant from the application of the salve, 20 mice received subc. injections of bismuth subnitrate in the head as well as the body, either immediately after or 12-15 hrs. after the S application. The head deposit, when made immediately after the S salve application, was distinctly blackened but less than the deposit underlying the salve; no reaction occurred in the cases in which the Bi salt was deposited 12-15 hrs. after the application of the salve. H_2S was not demonstrable in expired air but in 18 out of 25 cases its formation was demonstrated at the spot of application of the S salve. Clinical experiments showed no H_2S in the venous blood of 10 untreated healthy controls; H_2S was faintly demonstrable in 1 out of 5 healthy subjects previously treated with S salve; a more or less positive reaction occurred in nearly all of 15 cases of skin disease treated with S salve, the intensity of the reaction varying with the degree of skin defect and the time of observation, the blood showing the H_2S most distinctly 6-8 hrs. after the first application of S salve. The reduction of the S may be connected with the cysteine-cystine or glutathial-glutathionid oxid-reduction system. The results of comparison of the Berlin blue reaction in the normal and S-treated skin (on 40 white mice and 25 guinea-pigs) showed a more intense coloration of the S-treated skin. IV. A preliminary study on 18 healthy persons showed an average total S content in the blood serum of 157.3 mgm. %. After a 12-hour application of salve of 10% precipitated S, a rise in total S was observed exceeding the limits of the physiologic variation found in salves with benzoinated lard, yellow vaseline and eucerin as bases, within physiologic limits in salves with bases of ZnO paste or "Physiol C." Control experiments with 2% salicylic acid salves and artificial erythema showed slight rise in total S of blood serum, but so much less than that from the S salves as to indicate absorption as the cause of the changes following the use of the latter. A rise of total N accompanied but did not parallel the rise in total S; the theory is advanced that a part of the increased total S in the serum after absorption circulates in inorganic form. Several series of experiments on 6 and 12 persons without skin disease showed, after 12-hr. application of 100 gm. of 10% precipitated S salve, an increase in sulphate S and total S in the urine, the rise in the sulphate S exceeding that of the total S. Results varied with different bases in order similar to that previously

noted. No regular relation was observed between the effect on S economy and the changes in basal metabolism.

7122. **MÜLLER, JOHANNES.** Tierexperimentelle Untersuchungen über die Verteilung des Quecksilbers im Organismus und klinische Erfahrungen über die Ausscheidung desselben nach Salyrganinjektionen. (Unter besonderer Berücksichtigung der Pathologie und Therapie der Typhusbazillenträger.) *Arch. Exp. Path. u. Pharmakol.* 141(1/2): 1-18. 1929.—Salyrgan (2-6 cc.) was intraven. injected into 10 German shepherd dogs; 1 died 7 min. after receiving 6 cc.; 5 were killed in 20 min. by bleeding from the carotid under ether-chloroform narcosis; the others were killed, 2, 4, 6 and 10 hrs. resp. after injection. The bile, gall-bladder, kidneys, small intestine and blood were analyzed for Hg in all, and the bone-marrow, liver, skeletal muscle, suprarenals, large intestine, stomach, pancreas, spleen, brain, cerebrospinal fluid, lungs, urine and subcutaneous fatty tissue in some. The greatest percentage of Hg was found in the gall-bladder, the suprarenals, the kidneys and the large intestine. Observations on 5 typhoid carriers showed that 5 hrs. after injection of 1 cc. salyrgan (=36.22 mgm. Hg) 31.9 mgm. Hg had been excreted in the urine; 1.1 mgm. Hg appeared in the feces. Of the remaining 3.22 mgm. Hg, all but 1 mgm. was excreted through the feces and urine during the next 20 hrs. All but an insignificant part of the Hg injected, then, was excreted during the 24 hrs. following injection, by far the larger part through the urine. In dogs also the greater part was excreted through the urine.

7123. **NAHMMACHER, HANS.** Was ergibt die kindliche Gewichtskurve nach Vigantoldarreichung an Säuglinge, Wöchnerinnen und Schwangere? *Zeitschr. Kinderheilk.* 49(4): 454-460. 1930.—From comparison of results in 316 infants treated without, and 110 with vigantol, 661 puerperae without, and 226 with, and 162 gravidae treated without, and 45 with, it was concluded (opposed to results of Vogt) that vigantol given to the pregnant woman delays birth, and given to the mother or to the child increases the physiologic postnatal loss of weight and delays recovery of birth weight.

7124. **OLSEN, OTTO.** Om Virkningen af Insulin resorberet fra Mundens Slimhinde. [Action of insulin absorbed from the mucous membrane of the mouth.] *Ugeskr. Laeger* 91(9): 173. 1929.—Insulin was absorbed by the oral and lingual mucous membrane to produce a fall in blood sugar in diabetics.

7125. **ORESTANO, GIROLAMO.** Azione dei farmaci del gruppo della canfora sul respiro periodico da cocaina. [Effect of drugs of the camphor group on the periodic respiration of cocaine.] *Arch. Internat. Pharmacol. et Therap.* 35(3): 351-365. 5 fig. 1929.—Esetone, camphor, coramine and cardiazol stimulate respiration when given intraven. The isodynamic doses are approximately esetone 1, camphor 3, cardiazol 10, and coramine 20. None of these drugs injected simultaneously with or after cocaine hinder the production or cause disappearance of Cheyne-Stokes respiration. Only esetone prevents periodic respiration when injected before cocaine. Probably none of these drugs increase the resistance of the respiratory center to the paralyzing effect of cocaine; esetone apparently diminishes it. The action of the latter used previously to cocaine may be explained by the fact that the effect of esetone lasts for a considerable time and the effect of the cocaine is superimposed on it so that the center, already fatigued, is soon exhausted, without being able to maintain itself at that level of excitability necessary for the production of periodic respiration.—*I. H. Pierce.*

7126. **PACK, GEORGE T., ISABEL SCHARNAGEL, and J. ROSS VEAL.** The placental transmission of bismuth. *Amer. Jour. Syphilis* 14(2): 233-235. 1930.—Bi is transmitted through the placenta of the rabbit and cat when lethal doses are given intramuscularly to pregnant animals of these species. Pathologic changes in the fetal kidneys are not induced until the amount of Bi introduced into the pregnant animal approaches 60 times the therapeutic dose for human subjects.—*Authors' summary.*

7127. **PASCHKIS, KARL.** Zur Biologie des retikuloendothelialen Apparates. VII. Ueber Vergiftung des retikulo-endothelialen Apparates. Zugleich ein Beitrag zur Nephroseentstehung und zur Adsorptionstherapie. *Zeitschr. Ges. Exp. Med.* 67(1/2): 84-99. 5 fig. 1929.—The so-called "blockade" of the reticulo-endothelial system is discussed. In a previous paper it was suggested that it was not the mechanical filling of a cell with colloidal material which stops cell function but a sort of "poisoning" of the cell due to a reaction of the injected colloid (dye, metal, etc.) with the protoplasm. Using the method of Jansco (adsorption of a poison to a colloid that can be taken up by the reticulo-endothelial system) the poisoning of the reticulo-endothelial system with Janus green, adsorbed to cuprocollargol, was demonstrated by histological investigation. The vital functions of these poisoned cells were studied, using vital stains as a test: They were not able to take up lithion-carmin in granular form, which proved that their function was really damaged. But the poisoning with Janus green is not suitable for further studies of the function of the reticulo-endothelial system, because there is always a lesion of parenchymal cells (of the liver and bone-marrow) besides the lesion of the reticulo-endothelial system. It is possible that this lesion of parenchymal cells is due to a nutritional disturbance of the reticulo-endothelial cells towards the parenchyma, but it may be that the poison enters the liver cell (or bone-marrow cell), passing through the damaged reticulo-endothelial cell. Poisoning with optochin and with sublimate did not give any better results as far as the lesions of the parenchyma were concerned. Intravenous administration of Janus green alone (without cuprocollargol) does not affect the liver, spleen or bone-marrow, but causes severe lesions of the kidneys (tubular and glomerular nephrosis). As these lesions do not occur when Janus green adsorbed to cuprocollargol is injected, this is a new example of "parenteral adsorption therapy." Cuprocollargol alone, injected intravenously, causes a marked anemia, which is due to the Cu, not to the Ag, content of cuprocollargol.—*K. Paschkis.*

7128. **PELLATHY, S. v., und J. v. FERNBACH.** Ueber die Wirkung des Parathyreoideaextraktes auf das Blutbild. *Endokrinologie* 3(6): 406-412. 1929.—Parathyroid extracts administered subc. increased the number of myeloid cells. The effect seems to be through the nervous system rather than due to blood Ca. The effect is sympathotonic. It should be useful in vagotonic diseases such as asthma.—*B. Cunningham.*

7129. **PELLEGRINO, F., e G. CAIZZONE.** Azione del Selenio-Tellurio-Cobalto sul Ricambio Idrocarbonato. [Action of selenium, tellurium and cobalt on carbohydrate metabolism.] *Arch. Farmacol. Sper. e Sci. Aff.* 45(3): 75-80. 1928.—Selenic acid, telluric acid, and cobalt nitrate were injected intramuscularly into rabbits. Both selenic and telluric acids increased blood sugar. Their action was not due to the H ion since injection of equivalent HCl did not increase blood sugar. Injection of selenic or telluric acids (1 cc. of N/20 sol. per kgm.) following insulin did not neutralize the hypoglycemia. Intramuscular injection of 1 cc. of $Co(NO_3)_2$ per kgm. produced a small rise in blood sugar. Injection of $Co(NO_3)_2$ coincident with injection of $\frac{2}{3}$ unit of insulin in part neutralized the hypoglycemia.

7130. **PETOW, H., H. KOSTERLITZ, und H. PROBST.** Zur Frage des aktiven Eisens. III. Seine Wirkung auf die Blutregeneration bei der Toluylendiaminanämie des Hundes. *Zeitschr. Ges. Exp. Med.* 72(5/6): 717-725. 3 fig. 1930.—Small doses of toluylendiamine were used to produce in the dog an anemia like the secondary anemia following clinical cases of infection, carcinoma, etc.; 3 series of exps. were carried out on 5 dogs, including 1 control. In this anemia, notwithstanding abundant Fe in the diet, ferrum reductum and "benzidin-active" ferroferricarbonate stimulated the bone-marrow and thereby regeneration of the blood. The "benzidin-active" fer-

roferricarbonate had a more powerful action than the reduced Fe, a fact which the authors attribute, not to a greater "activity," but possibly to a better solubility in the gastric juice and greater absorbability.

7131. PIGHINI, GIACOMO. Ricerche sul liquor folliculi. V. L'ormonizzazione sessuale della donna nelle malattie nervose e mentali. [Studies on the liquor folliculi. V. Sexual hormone treatment of nervous and mental diseases in women.] *Riv. Sperim. Freniatria* 53 (1/2) : 1-33. 1929.—For psychoneuroses and effective psychoses in women a highly concentrated extract of liquor folliculi ("estrofollicolina") has been successfully used. The results in 22 cases tend to confirm the theory that dementia praecox arises from congenital causes affecting principally and primarily the brain, with frequent concomitant alterations in the genito-sexual endocrine system (anterior lobe of the hypophysis and gonads). "Estrofollicolina" in some cases ameliorates the condition by influencing favorably the ovarian dysfunction; in other cases it is without effect either on the sexual dysfunction or on the course of the disease.—*From author's summary (transl.)*.

7132. POLONOVSKI, MICHEL, P. NAYRAC, et J. TIPREZ. Le N-oxyde de morphine en thérapeutique. *Bull. Acad. Méd.* 103 (5) : 174-178. 1930.

7133. POULSSON, LEIF T. Beitrag zur Kenntnis der Wirkung des Pituitrins auf die Ionenausscheidung. *Zeitschr. Ges. Exp. Med.* 72 (1/2) : 232-243. 2 fig. 1930.—Of 20 exps. described, part were performed on Poulsson himself and part on healthy medical students. Pituitary (10-15 units) was intramuscularly injected in the morning with the subjects fasting, after which food was taken as usual; hourly urine determinations were made. Characteristic changes in the ion content of the urine appeared. The total fixed base content rose in proportion to the Na content, while the NH_3 and the titratable acidity declined sharply. Simultaneously the reaction of the urine became more alkaline.

7134. PŘIBYL, E. Farmakotherapeutický účinek koloidního hydroxydu hořečnatého na záněty jater a ledvin toxikogenního původu. [The pharmacotherapeutic action of colloidal magnesium hydroxide in experimental hepatitis and nephritis of toxic origin.] *Biol. Spisy Vysoké Školy Zvěrolékařské Brno (Publ. Biol. École Vétérinaires)* 6: 291-318. 1927.—In this experimental work the therapeutic action of $Mg(OH)_2$ in colloidal state (introduced in medical practice by Bečka and sold under the trade name Polysan) in inflammatory processes in liver and kidneys has been studied. One group of rabbits was poisoned by P or by As in order to induce hepatitis, a 2nd by uranium nitrate to induce nephritis. The clinical changes in P and As poisoning, respectively, have been measured by determining the grade of icterus, occurrence of albumin and bilirubin in urine and the level of N. P. N. in blood. The clinical behavior of animals has been daily recorded. In nephritis the function of kidneys has been followed by determining the N. P. N. in blood, the excretion of phenolsulphonephthalein in urine and the grade of albuminuria and bilirubinuria. Also the temperature and body weight have been observed. When the mentioned symptoms of hepatitis or nephritis have occurred, the emulsion of Polysan has been injected for several days intraven. and all further changes in state of treated animals have been recorded and compared with those of control rabbits. $Mg(OH)_2$ (Polysan) acted in P hepatitis as follows: the N. P. N. decreased which may be attributed to decreased autolysis of liver tissue. The disappearance of bilirubin and albumin was observed. In one case the exitus was delayed for 10 days, otherwise the animals recovered from poisoning completely. In As poisoning similar therapeutic influence of $Mg(OH)_2$ was observed. In nephritis several doses of Polysan caused very great improvement of kidney function: there was a decrease of N. P. N. in the blood, and an increase of phenolsulphonephthalein excreted in urine. The albuminuria disappeared and subnormal temperature reached its physiological height. This improvement in function has been observed also in rabbits havng symptoms of advanced uremia: edema, anuria etc. By histological examination of the liver poisoned by P it was found that the liver of the rabbit, into which $Mg(OH)_2$ had been injected, was in a state of hyperemia. Also very prominent processes of regeneration were evident. The liver of control rabbits showed the picture of advanced inflammation, fatty degeneration and necrosis. In the kidneys of the rabbit treated by $Mg(OH)_2$ the hyperemic state was found also, whereas the kidneys of control rabbits showed the picture of typical tubulonephritis. From the experiments it may be concluded that $Mg(OH)_2$ has a healing action on inflammatory processes in liver and kidneys. It is believed to neutralise the increased acidity in inflamed tissue which is necessary for inflammatory processes and therefore acts directly against inflammation. The Mg-ion liberated by neutralisation influences the processes of regeneration of tissue by catalytic action.—*Author's summary.*

7135. QUIN, J. I. The toxic properties of Cucumis myriocarpus Naud., and Cucumis africanus Linn. *Union So. Africa Dept. Agric.* 15th Ann. Rept. Dir. Vet. Serv. 2 (5/9) : 769-775. 1929.—*C. myriocarpus* and *C. africanus*, especially their ripe fruits, are toxic to animals. The poisonous juice is stable to desiccation and boiling for long periods. When given in sufficient amount it is rapidly fatal, although the symptoms and frequently the post-mortem findings are not very striking. Except for the yield, which in *C. africanus* is much less than in *C. myriocarpus*, the 2 substances appear identical. The poison is non-alkaloidal and non-glucosidal and probably of a resinous nature. On injection it is rapidly fatal, death coinciding with a severe pulmonary edema. From the nature of its action, it is difficult to reach an understanding of the factors involved. It seems that the poison is readily taken up by the blood-stream even following subc. injection, and passed through the heart into the pulmonary circulation. In the lungs gross injury is effected, the poison apparently acting directly on the endothelial lining. This assumption, if correct, would imply a physico-chemical disturbance in the cell body rather than a morphological change. Thus in no case was pulmonary hemorrhage noticeable, i.e., actual tearing of blood-vessels can be excluded, and yet the effect on the minute vessel wall must be very significant when large amounts of apparently whole plasma containing protein molecules are capable of being forced through. There seems to be little doubt that this is a case of a primary pulmonary edema, since the heart-beat remains normal until shortly before death, when asphyxia sets in. The possibility of vasomotor disturbances accounting for the edema seems remote. Blood-pressure tracings obtained from decerebrate dogs and rabbits show practically no deviation after intraven. injection of extracts. In such cases the respiration and heart-beat come to an end from the same cause, i.e., the marked pulmonary edema. When this appears, but not before, there is a marked fall in the general blood-pressure. With small animals as much as half the plasma may be lost in this way, while in sheep a concentration of the red corpuscles from a normal of ± 25% to 75-80% is frequently noticed.

7136. RATH, ERICH. Zur Pharmakologie gebromter Baldriansäureester. *Arch. Exp. Path. u. Pharmakol.* 142 (3/4) : 162-165. 1929.—Exps. on fish and mice indicated that the introduction of a Br atom into the acid radical of isovaleryl amylene hydrate produces a much more active compound than if the Br is introduced in the alcoholic radical.—*Author's summary (transl.)*.

7137. REDNIK, T. Die Beeinflussung der Medikamente auf die Dextrose-Belastungs-Blutzuckerkurven, als Leberfunktions-Prüfung. *Zeitschr. Klin. Med.* 109 (6) : 720-724. 1929.—On the assumption that the hyperglycemia following the oral administration of carbohydrate is due not to absorbed sugar but to a reflex action on the liver, an attempt was made to influence the blood sugar rise after oral administration of bread or dextrose by the administration of $CaCl_2$ by vein (a procedure which reduces tonus of sympathetic and of parasympathetic)

and also by the oral administration of gynergen (reduction of sympathetic tone) simultaneously with the ingested sugar. Results fully confirm those of Hetenye and Pogany. Following the administration of a sufficient dosage of carbohydrate, a blood sugar rise occurs in man —with normal liver function. This reflex hyperglycemia can be diminished by Ca or ergotamine. The latter drug may inhibit the reaction entirely. A diseased (cirrhotic) liver does not react similarly, i.e., no reflex hyperglycemia occurs and Ca and ergotamine are consequently without effect. It is suggested that the alteration of the sugar binding power of the liver by Ca or ergotamine (implied by the reflex hyperglycemia following sugar adminstration) offers a satisfactory test for liver function.—*O. W. Barlow.*

7138. **REICHLE, HERBERT S.** Toxic cirrhosis of liver due to cinchophen. *Arch. Internal Med.* 44(2): 281-288. 4 fig. 1929.—Report of 2 cases with review of 47 previously published.

7139. **REID, W. L.** Changes in the volume of the kidney in the intact animal; a plethysmographic study with especial reference to diuretics. *Amer. Jour. Physiol.* 90(1): 157-167. 12 fig. 1929.—A method for plethysmographic study of the kidney is described. It is an adaptation of Hargis' collodion plethysmograph. Observations were made on virtually intact dogs. Simultaneous tracings of carotid bl. press. were made under local anesthesia in some of the animals. The effects of caffeine, theobromine sodio-salicylate, theophylline ethylene diamine, pituitrin, digitalis, merbaphen, nitrites, epinephrine, spinal anesthesia and distilled H_2O were studied. Results agreed with those of other workers on anesthetized dogs. From 0.5-1 cc. dist. H_2O per kgm. produced a temporary but pronounced decrease in volume, without change in blood pressure.—*M. R. Freeland.*

7140. **RENTZ, EDUARD.** Zur Pharmakodynamik des Chlorophylls. *Skand. Arch. Physiol.* 56(1/4): 36-117. 40 fig. 1929.—Chlorophyll extracts were used in exps. on living animals or surviving tissues. Moderate doses of chlorophyll increase the tonus and the height and frequency of contraction of the isolated rabbit intestine, while higher concentrations generally reduce movements after momentary increase. The effect of the parasympathetic stimulants on the intestine is increased by moderate doses of chlorophyll, while stronger doses reduce or completely check the results. The effect of atropine is not greatly influenced by chlorophyll; at most it is somewhat weakened. The effect of epinephrine is plainly prolonged. $BaCl_2$ with strong chlorophyll doses continues very active. Moderate chlorophyll doses stimulate the rabbit uterus somewhat in movement and in tonus. Strong and very strong concentrations act like epinephrine. The effect is reversible. The effect of epinephrine itself is prolonged by chlorophyll. Atropine neutralizes the influence of chlorophyll. After strong doses of atropine strong chlorophyll doses diminish tonus. $BaCl_2$ is unchanged in effect. On the isolated frog heart chlorophyll increases systole and decreases the frequency. Chlorophyll does not increase the effect of epinephrine. On hearts treated with ergotamine chlorophyll is as effective as on untreated hearts. The effect of acetylcholine is reduced or completely offset by stronger chlorophyll doses. Electrical stimulation of the vagus after strong chlorophyll doses is weakened or ineffective. Also the response of the sympathetic nerve is lessened. On preparations of isolated circulatory systems of frogs chlorophyll extract produces widening of the vessels, and in spite of this the effect of epinephrine is increased by chlorophyll and the action of $BaCl_2$ is unaffected. Tonus and the effect of epinephrine upon the rabbit aorta are increased by chlorophyll. Blood pressure exps. on rabbits show slight improvement of respiration by chlorophyll, a slight increase in blood pressure, an insignificant reduction in the pulse rate, a widening of kidney and intestinal blood vessels, while the leg blood vessels remain either unaffected or contract slightly. Strong chlorophyll doses produce optimal results in respiration, blood pressure, kidney and intestinal blood vessels. The effect of epinephrine is not visibly increased. Blood pressure experiments in the cat are similar, but the effect of epinephrine on blood pressure and on the kidney vessels is increased, although chlorophyll widens, though slightly, the kidney vessels. Chlorophyll in moderate doses can, therefore, be considered a material which stimulates smooth muscle and increases the sensitiveness of the sympathetic nervous system. The question whether the increase in the effect of epinephrine by chlorophyll is due to decrease of oxidation of epinephrine, especially since chlorophyll is involved in intracellular respiration, must remain unanswered for the present, as well as the question of increase in permeability by chlorophyll solutions and their effect upon the action of epinephrine.—*G. J. Peirce.*

7141. **REZNIKOFF, PAUL.** Rectal administration of liver extract (cod). *Jour. Amer. Med. Assoc.* 93(5): 367-368. 1929.—Preliminary paper. Administration of cod liver extract to a pneumonia patient with vomiting resulted in cessation of vomiting, increase in hemoglobin %, and in red blood cell count.

7142. **RIKL, ALEXANDER.** Die lokale Reizwirkung der Narkotika. *Arch. Exp. Pathol. und Pharmakol.* 133 (3/4): 192-201. 1928.—The limiting concentrations of many alcohols and other narcotics in regard to their burning or stinging effect on the human eye and tongue were determined. An homologous regularity was found, as Führer observed in the narcotic activity of homologous alcohols on the frog heart. The local irritant action of the narcotics used runs parallel with the strength of their narcotic effect. No numerical relationship between the described results and the central stimulating action of narcotics can be established. Phenol, camphor and menthol, tested comparatively, show by far the strongest local irritation.—*I. H. Pierce.*

7143. **ROOSEN, R.** Zur Isaminblautherapie der bösartigen Geschwülste. *Zeitschr. Krebsforsch.* 31(5): 506-516. 1930.—The action of the dye appears to be one of dehydration of the tumor tissue, ascribed to upset of intracellular equilibrium. Much of its effectiveness depends on sufficient dosage, since only part of the administered dye is absorbed by the tumor tissue, and as tumors differ greatly in their affinity for the dye, larger doses are necessary in the case of those with low absorptive power. With insufficient doses, the absorption and its effects are limited to the periphery of the tumor, leaving the central portion free to grow. In regard to combined therapy, x-ray, at least in large doses, interferes with the use of isamine-blue, as it tends to diminish its absorption. Concerning its combined use with bismuth-iatren, very careful technique is necessary, for if the inflammatory reaction induced by the iatren regresses before there is sufficient storage of isamine-blue, the latter is gravely interfered with. The possibility is suggested of promoting the absorption of the dye in certain regions by administration of substances acting through the nervous system, e.g., choline in gastric cancer, the general splanchnic dilatation induced by small doses promoting deposition of the dyestuff. Animal experimentation is of little value in this particular clinical problem, since the inoculated tumors of animals are as a rule rather well delimited, so that in them the perineoplastic deposition, so important in human tumors, is without effect. Diathermy along with isamine-blue tends to increase its absorption, but in intensive doses there is danger of intoxication from degeneration products, particularly in the case of superficial cancers. To avoid this, either the diathermic dosage must be carefully regulated, or as much of the tumor as possible should first be extirpated surgically.—*H. E. Eggers.*

7144. **ROSENTHAL, SANDFORD M.** Some effects of alcohol upon the normal and damaged liver. *Jour. Pharmacol. & Exp. Ther.* 38(3): 291-301. 1930.—Alcohol orally administered to normal dogs (2 cc. per kgm.) produces no increase of urobilin in the urine or bilirubin in the blood. There is a slight impairment indicated by the bromsulphthalein test, which returns to normal in 24 hrs. Alcohol produces no greater distur-

bance of function in dogs whose livers have been damaged by $CHCl_3$ or CCl_4 than it does in normal dogs. In spite of the negligible disturbance as shown by tests of liver function, alcohol greatly increases the susceptibility of dogs to $CHCl_3$ (by inhalation) even after the visible effects of alcohol have worn off. A 2 hr. period of anesthesia was fatal to 6 of 10 dogs who had received 2 cc. of alcohol per kgm. (by mouth) 3 to 4 hrs. prior to the anesthetic. As a control 10 dogs received a similar period of $CHCl_3$ anesthesia alone, without a fatality.—*Author's summary.*

7145. SALANT, WILLIAM, and KEEVE BRODMAN. The effect of mercury on intestinal motility. *Jour. Pharmacol. & Exp. Therap.* 37(1): 55-66. 1929.—Soluble salts of Hg stimulated intestinal movements in different animals, their contractions being increased by small doses of pilocarpine. Stimulation of the vagi by the interrupted current was more effective after than before Hg. The effect was also increased in animals in which Ca deficiency was produced by the repeated administration of Na-oxalate. Stimulation by Hg was often preceded by primary inhibition of short duration. Atropine usually prevented stimulation of the isolated intestine of the rat by Hg. On the basis of the above results it was concluded that the movements of the intestine provoked by Hg were due to stimulation of the parasympathetic endings. Occasional failures of the intestine to respond to Hg were discussed. The conclusion was reached that they were due to causes other than excessive stimulation of the splanchnics. Evidence was also adduced indicating that Hg depressed the Auerbach plexus.—*Authors' summary.*

7146. SALANT, WILLIAM, and KEEVE BRODMAN. Functional changes in the autonomic system and the action of mercury. *Jour. Pharmacol. & Exp. Ther.* 37(2): 121-130. 1929.—Small and medium doses of adrenalin increase but large doses decrease the resistance to Hg. Its toxicity is also considerably diminished by moderate amounts of ephedrine. Hg was most toxic for the heart when given after paralysis of the sympathetic by ergotamine. The action of Hg is also increased by cardiac inhibition but not nearly to the same extent as by paralysis of the accelerators. Complete denervation of the heart by atropine and ergotamine produces effects on the action of Hg similar to those observed when it is given after ergotamine only. The relation of the autonomic system to the action of Hg was discussed and the beneficial effects of small doses of adrenalin analyzed. It was concluded that the resistance of the heart depended upon the balance between the sympathetic and parasympathetic systems.—*Authors' summary.*

7147. SCALA, VINCENZO. La chemioterapia del granuloma maligno. [Chemotherapy of malignant granuloma.] *Minerva Med.* 9(52): 1041-1050. 7 fig. 1929.—Biopsies in 4 cases of Hodgkin's disease treated with antimony (given in the form of "stibional") showed that in a short time an intense connective tissue sclerosis was completely replacing the typical granulomatous process. It is believed to act in the disease rather by stimulating the reticulo-endothelial system to resistance than by directly antagonizing the pathogenic agent.

7148. SCHAZILLO, B. A. Beiträge zum Studium über die Bedeutung der Blutdrüsen für den Verdauungstrakt. Die Wirkung von Adrenalin und Insulin auf die Sekretion des Dünndarmsaftes. *Arch. Verdauungs-krankh.* 45(3/4): 264-271. 1929.—In a fasting dog with a Vella fistula adrenaline (1 mgm. subc.) was found to increase secretion about 3-fold; but after feeding with meat extract an increase could only be obtained by intravenously administered adrenaline. Insulin (5 units subc.) increased the secretion both when fasting and after feeding. It is suggested that intestinal secretion depends on changes in the tone of the autonomic system, with relative parasympathetic preponderance at the height of digestion.—*R. J. Brocklehurst.*

7150. SEBENING, W. Physiologische Grundlagen der Avertinnarkose. *Schmerz* 2(11): 403-439. 8 fig. 1930.—A method is described for the quantitative determination of avertin absorption during rectal narcosis. Rate of absorption of avertin determines rate and depth of narcosis. Perfusion of the dog liver by avertin caused injury that was similar to that produced by phlorhizin. From 20-30 min. after avertin was introduced into the rectum it reached its highest concentration in the blood. The highest concentration found was between 5-9.5 mgm. %; values under 4 mgm. % produced an incomplete general narcosis. The organs in the body which contained the highest percentage of lipids contained the highest amount of avertin, i.e., the brain. Cerebrospinal fluid sometimes contained less avertin than the blood. The blood corpuscles contained from 2-7.5 times as much avertin as did the plasma.

7151. SHERIF, M. A. F. The effect of certain drugs on the oxidation processes of mammalian nerve tissue. *Jour. Pharmacol. & Exp. Ther.* 38(1): 11-29. 1930.—The effect of various drugs on the oxidation processes of nerve tissue has been investigated by 2 methods: (*a*) by observing the time for reduction of methylene blue, and (*b*) by the use of a modified Barcroft apparatus. Generally, the result of either method confirms the other. Cocaine HCl inhibits O usage in concentrations of 0.2 to 1.0%. Novocaine borate has a similar action, but requires nearly double the concentration to produce a comparable effect. Urethane is effective only in still higher concentrations. Caffeine citrate increases oxidation in concentrations lower than 0.5%. Above this concentration oxidation is diminished. Oxidation is inhibited, not only by drugs which are known to diminish conduction in nerve fibers, but by certain other substances which do not possess the properties of local anesthetics. While glucose 0.1% has no effect on O uptake, galactose in the same percentage concentration enables the nerve to take up O at a uniform rate for at least 3 hrs., whereas in the control nerves the O uptake falls off after the 1st hr.—*Author's summary.*

7152. SHIROTA, RYOHEI. Der Einfluss verschiedener Pharmaka auf den Gasstoffwechsel der Niere. [Japanese.] *Hokkaido Igaku Zasshi* 5: 377-399. 1927.—Rabbits for the most part and sometimes cats were used for the exps. The apparatus was Plesch's gas analyzer with M. Miva's modification. Fifteen min. after intraven. injection of such compounds of Bi as castis, muthanol, neotrepol and trepol O-consumption of the kidney increased, secretion of urine decreased at the same time. Larger doses of these compounds diminished the gas exchange of the kidney. In most experiments with trional the O-consumption of the kidney was also increased. With uranium compounds both urine secretion and gas exchange of the kidney were usually increased. The last was diminished however in cases of acute U nephritis, especially in cases when advanced regressive changes in the tubules were present. Urotropin and helmitol used even in larger doses failed to alter O-consumption of the kidney, but caused a well marked diuresis. The compounds of the phenol group, given in doses which ordinarily do not cause convulsions or blood changes, are able to raise the gas exchange of kidney. The secretion of urine is always diminished with such doses, while smaller ones tend to increase it. The intensity of action in raising the gas exchange of the kidney seems to depend very much on the toxicity of the compound used; i.e., the more toxic the compound, the stronger the action. With regard to the intensity of action the compounds can be arranged as follows: pyrocatechin, hydrochinon, resorcin, phenol and pyrogallol. The action of phloroglucin on the gas exchange of the kidney is practically negligible.—*Author (courtesy Japanese Jour. Med. Sci. IV) (transl. by B. Siaulis).*

7153. SHPINER, LEONARD BENJAMIN. Blueberry leaf extract overdosage. *Arch. Internal Med.* 44(2): 204-208. 1929.—In view of the recently demonstrated

antidiabetic effect of blueberry leaf extract (myrtomel) and also of von Noorden's findings of hepatic necrosis following intraven. injection of this extract, exps. were made with oral overdosage (2 to 4 times the therapeutic dose) on 2 normal and 2 partially pancreatectomized dogs. No toxic or untoward results were observed.

7154. **SIMON, A. Ergänzung der Arbeit: "Über die Beeinflussung der Leberautolyse durch Insulin und Thyroxin" von A. Simon und P. Weiner.** *Biochem. Zeitschr.* 215(1/3): 102-105. 1929.—Additional data are presented which show that thyroxin decreases autolysis somewhat in a phosphate buffer mixture. Insulin apparently does not influence autolysis.

7155. **SOBOL, M. E., und Z. J. SVETNIK. Die Wirkung des Wismut auf das Nervensystem.** *Arch. Psychiatr. u. Nervenkrank.* 88(4): 586-597. 4 fig. 1929.—The clinical results and pathologic change induced by intramuscular injection of insoluble Bi salts were observed in 3 rabbits. It is concluded that, so far as the nervous system is concerned, metallic Bi is not a parenchymatous poison. Chronic poisoning with insoluble Bi salts produces a marked alteration of the chloroid plexus, of the cerebral vessels and of the meninges, without alterations in brain-substance; nor does injury to the hematoencephalic barrier through poisoning by a heavy metal necessarily involve parenchymatous alterations. The nervous complications which in rare cases occur after long-continued administration of Bi salts are to be regarded as secondary and of vascular origin; not as primary alterations in cerebral functions.

7156. **SPYROPOULOS, CHARALAMBOS. Experimentelle Prüfung der bakteriziden Wirkung des Thorium X-Degea in Lösung und in Salbe gegenüber eigigen augen-pathogenen Bakterien in vitro.** *Arch. Augenheilk.* 100/101: 418-438. 1 fig. 1929.—In testing the bactericidal action of thorium X the author used the following cultures—staph. aureus, staph. albus, pneumococcus, gonococcus, streptococcus, pseudomonas aeruginosa, and Morax-Axenfeld and xerosis organisms grown either in serum bouillon or suspended in physiological saline. While in solutions containing 10,000 e.s.E. per cc. doses there was some bactericidal action after a 16 hr. exposure, and while in salves 2000 to 5000 e.s.E. per cc. proved bactericidal at distances under 10 mm. in 11 to 12 hr. exposures, it is believed that there is little likelihood of favorable action on eye infections as the action is very superficial and the organisms are enveloped in secretion or enclosed within cells.—*H. F. Smyth.*

7157. **STANOJEVIC, LAZA. Die ergographische Leistungsfähigkeit nach dem physiologischen und nach dem mit verschiedenen hypnotischen Mitteln erzeugten Schlafe. Eine psychopharmakologische Studie.** *Monatsschr. Psychiatr. und Neurol.* 74(1/2): 121-128. 5 fig. 1929. —The subjects of investigation were normal persons, former patients now in remission after acute psychoses, and psychopathic persons (number not stated). Ergographic records were taken after sleep induced with narcotics (adalin, a urethane derivative; neodorm, and phanodorm) and after physiologic sleep. A decided difference appears in the ergographic record of capacity for exertion after physiologic sleep and artificially induced sleep. Hypnotics appear to affect the cerebral cortex as well as various points in the central nervous system. The ergogram obtained after sleep induced by hypnotics is short and irregular, owing to association and innervation processes induced by the drug. Capacity for physical exertion is apparently dependent primarily on the central nervous system, the peripheral neuromuscular apparatus appearing to play only a secondary part therein.

7158. **STARK, W. BERKELEY. Irrigations with aqueous solution. Their effect on the membranes of the upper respiratory tract of the rabbit.** *Arch. Otolaryngol.* 8(1): 47-55. 5 fig. 1928.—The nasal fossae of 24 rabbits were irrigated with 0.9% NaCl solution, tap water, or 2% NaCl solution, at a temperature of 40° C., and 8 healthy rabbits were used as controls. Irrigations, varying from 3 to 24, were made daily. Examinations were made in some instances a few minutes after the last irrigation; in others, 24 hrs. afterward. At necropsy, 75% of the rabbits irrigated were found to have mucopurulent secretion in the nasal fossae and in the paranasal sinuses. The animals examined from 15 to 20 min. after irrigation showed that the paranasal sinuses on both sides were filled with irrigating fluid, whereas the sinuses of rabbits examined 24 hrs. after irrigation were clear of it. Of the 18 rabbits having mucopurulent sinusitis, the sinusitis was on the right side in 3, on the left in 4 and on both sides in 11. The reaction of the nasal mucous membrane to 2% NaCl solution and to tap water was more marked than the reaction to the 0.9% NaCl solution. Varying degrees of change were noted macroscopically and microscopically in the mucous membrane: hyperemia with marked leukocytic infiltration, increased glandular activity, and increase in the size of vacuoles and epithelial cells.—*Author's summary.*

7159. **STAUB, H., und A. JEZLER. Zum Synthalinmechanismus.** *Zeitschr. Klin. Med.* 112(1/2): 1-18. 5 fig. 1929.—In animals previously treated with phlorhizin, large regular doses of synthalin subc. or intraven. decreased the amount of urine excreted. If a guanidine preparation was injected into the renal artery a marked polyuria was produced. The blood in the renal vein became bright red. Polyuria was produced by inhibition of oxidation, following injury to the tubules and paralysis of the blood vessels. Polyuria followed oliguria. Synthalin did not act on the kidney itself since increased blood sugar was not followed by increased sugar in the urine. Stool analyses of diabetics before and after synthalin administration showed a disturbance in fat digestion and absorption, in those cases in which abdominal distress had followed administration of guanidine. The toxic action of synthalin was due to a disturbance of enzyme action, especially of the pancreas. However, enzyme tests on the stool were negative. Lactic acid appeared in the human urine after the usual dose of synthalin; but did not as a rule appear in rabbits in which synthalin had produced hypoglycemia.

7160. **STEPHAN, RICHARD. Ueber die Wirkungsart des gallensauren Insulins bei subkutaner Anwendungsform.** *Deutsche Med. Wochenschr.* 56(3): 88-91. 1930.—Addition of Na desoxycholate to the insulin molecule produced a drug having the same effect on blood-sugar as insulin, but with none of the subjective symptoms found with insulin injection. The Na desoxycholate compound was suitable for oral or subc. administration.

7162. **SUGIURA, KANEMATSU, and STANLEY R. BENEDICT. The influence of suprarenalin (epinephrin) on the growth of carcinoma and sarcoma in animals.** *Jour. Cancer Res.* 14(4): 487-501. 5 fig. 1930.—The toxic action of suprarenalin on the Flexner-Jobling rat carcinoma and the Rous chicken sarcoma has been investigated in 3 different ways, namely, (a) injection directly into and around the tumor, (b) injection subc. at a point away from the tumor, and (c) in vitro. In 58 rats with 56 controls inoculated with Flexner-Jobling rat carcinoma and 12 chickens inoculated with Rous chicken sarcoma, both series treated with repeated intratumoral injections of suprarenalin, the development of small tumors was completely inhibited, while large tumors were seldom beneficially affected. Metastases of the chicken sarcoma were not affected by treatment; and in 60 carcinoma-bearing rats treatment with subc. injections of suprarenalin at points remote from the tumor did not hinder the development of the latter. In vitro experiments indicate that the proliferating capacity of the Flexner-Jobling rat carcinoma was partially destroyed by suprarenalin, but the Rous chicken sarcoma was unaffected as respects its growth after implantation. Hence, any possible therapeutic value of suprarenalin (epinephrin) for cancer treatment is limited to local application.

7163. **TAINTER, M. L. Comparative effects of**

Ephedrine and Epinephrine on blood pressure, pulse and respiration with reference to their alteration by cocaine. *Jour. Pharmacol. & Exp. Therap.* 36(4): 569-594. 4 fig. 1929.—The responses of blood pressure and pulse and respiratory rates to ephedrine and epinephrine were compared in uncocainized and cocainized cats and dogs. The responses of all the functions studied decreased progressively with several successive intraven. injections of different doses of ephedrine, the decreases being more marked with increasing doses; but the diminution in pressor response to the second injection of ephedrine, which is the important injection in the phenomenon of cocaine-desensitization to ephedrine, was practically insignificant. On the other hand, the responses of the same functions tended to increase, if anything, with successive injections of epinephrine in the dosage used. The stellate ganglion is not demonstrably concerned either in the circulatory actions of ephedrine, contrary to the claims in the literature, or in the cocaine-desensitization to ephedrine. Cocainization of cats and dogs definitely desensitizes, i.e., prevents or greatly decreases, the pressor, cardiac and respiratory responses to ephedrine, and simultaneously sensitizes the pressor and cardiac, and may reverse the respiratory, responses to epinephrine, a truly sympathomimetic drug. Cocainization is thus effective with or without preliminary injections of control doses of the amines. The use of the pressor responses of the cocainized organism is a valuable pharmacological method for the analysis and classification of drugs in respect of sympathicotropic (truly "sympathomimetic") and pseudo-sympathicotropic actions, and the results by this method correlate with those obtained on the ergotized (ergotoxinized) organism. The significance of both the cocainized and ergotized organisms in pharmacological studies is discussed and the correlation of the two methods which holds for epinephrine, tyramine, ephedrine and phenylaminoethanol is pointed out; of these drugs, only epinephrine is sympathicotropic.—*Author's summary.*

7164. **TAKAHASHI, YOSHIO. Über den Unterschied zwischen Dünn- und Dickdarm bei verschiedenen Tieren in ihrer Reaktion auf einege Nervenmuskelgifte.** [Japanese.] *Okayama Igaku Kwai Zasshi* 39: 977-997. 1927.—The intestines of rabbits, guinea pigs, rats, dogs and cats were used. From all animals, the small intestine was the more sensitive to epinephrine. The action was usually inhibitory, but in young rats and in rabbits the large intestine often showed a stimulation. (Differing distribution of sympathetic augmentor fibers.) Ephedrine and mydriatin in small doses produced always a sympathicomimetic effect, in larger doses a direct muscular stimulation. The large intestine was generally more sensitive to pilocarpine, certain exceptions indicating differences in parasympathetic arrangement. Small doses of tyramine in the rabbit inhibit the small intestine and stimulate the large, the opposite occurring in the guinea pig. Rats and cats always showed a depression. When the dose was increased tyramine became always a stimulant, the large intestine being the more sensitive in any case. Ba, also, acts more readily on the large. The differences in responses to atropine follow the differences in parasympathetic predominance. The action of a drug upon the small intestine can not be taken as the story of its total effects in the intestinal tract because of these variations.—*Author* (*courtesy Jap. Jour. Med. Sci. IV*) (*transl. by C. Reynolds*).

7165. **TAKEDA, MASAO. On the cause of the change in the blood coagulability due to the intravenous infusion of hypo- and hypertonic salt solutions.** (Orig. in Japanese p. 125-143.) *Folia Pharmacol. Japonica* (*Breviaria*) 8(3): 1-2. 1930.—After intraven. injection of 50 c. c. per kgm. of NaCl at body temperature (0.6, 0.9, 1.8, 3.6, and 4.5%), into rabbits at the rate of 10 c. c. per kgm. per min., the clotting time of the blood, and the fibrinogen, thrombin, thrombokinase and Ca content were determined. The blood coagulability was always accelerated, showing a maximal effect just after injection. It was most marked with a 1.8% salt sol. The fibrinogen content did not change, whereas the thrombin content was, in general, augmented with the increased blood coagulability. Blood-platelets and leucocytes increased with the augmentation of coagulability and returned to the normal parallel with the latter. The blood Ca was not perceptibly increased by the infusion. It is concluded that in the augmentation of blood coagulability due to the infusion of salt solutions the increase in thrombokinase, which is formed by the destruction of blood-platelets and leucocytes, plays an important rôle, and moreover the increase in the thrombin content is of no little significance in this connection, but fibrinogen and Ca have little or no bearing on the changed coagulability.

7166. **TANAKA, HISASHI. Über den Einfluss des Insulins und des Pituitrins auf die Gerinnbarkeit des Blutes.** [With German summary, Breviaria p. 32.] *Folia Pharmacol. Japonica* 7(3): 422-428. 1928.—Insulin in vitro did not change the coagulation time of blood in rabbits. After intraven. injection of small doses of insulin (0.3-0.5 units per kgm.) there was at 1st a delay, later an acceleration of coagulation. Intensity and duration of the effect differ in different animals. Small doses of pituitrin (0.05-0.3 cc. per kgm. intraven.) delay coagulation; in larger doses (.5 cc. for example) pituitary extract at 1st inhibits coagulation, then hastens it. The anti-coagulating effect which pituitary extract has in vitro in addition to that of the citrate added to plasma is neutralized by NaOH. In the strict sense of the word epinephrine does not act as a coagulant for blood in vitro.

7167. **THOMPSON, MARVIN R. The pharmacology of ergot with special reference to biological assay and standardization. Part IV. Study of aqueous extracts of ergot.** *Jour. Amer. Pharmaceut. Assoc.* 19(1): 11-23. 1930.

7168. **THOMPSON, WILLARD OWEN, ALLEN G. BRAILEY, PHEBE K. THOMPSON, and EDWARD G. THORP. The range of effective iodine dosage in exophthalmic goiter. I. The effect on basal metabolism of rest and of the daily administration of one drop of compound solution of iodine.** *Arch. Internal Med.* 45(2): 261-281. 1930.—During the daily administration of 1 drop of compound solution of I (about 6 mgm. of I) to 17 unselected hospital patients with exophthalmic goiter, 15 showed a reduction of 15 to 49 points in basal metabolism, and 2 showed no change. The reduction appeared to be as great as that noted by other observers on much larger doses. A maximum decrease in basal metabolism also appeared to occur in most outpatients during the administration of 1 drop daily. In the house patients, the administration of 1 drop daily caused a maximum reduction in basal metabolism in 7 days, on the average. The time that elapsed between the beginning of I administration and the onset of a decrease in basal metabolism varied from 1 to 4 days. In 5 of the cases it had started within 24 hrs. after administering only 6 mgm. of I.—*From authors' summary.*

7169. **THOMPSON, WILLARD OWEN, EDWARD G. THORP, PHEBE K. THOMPSON, and ARCHIBALD C. COHEN. The range of effective iodine dosage in exophthalmic goiter. II. The effect on basal metabolism of the daily administration of one-half drop of compound solution of iodine.** *Arch. Internal Med.* 45(3): 420-429. 1930.—During the administration of ½ drop of compound solution of I (3 mgm. of I) daily to 20 unselected hospital patients with exophthalmic goiter, 13 showed a significant reduction in basal metabolism, 5 showed no change and 2 showed an increase. Seven showed a lower level of basal metabolism during the subsequent administration of 30 drops daily than during the administration of ½ drop daily. The average reduction in basal metabolism during the administration of ½ drop of compound solution of I daily was 14 points (from plus 40 to plus 26%)—which was only about ½ as great as that during the administration of 1 drop daily. The total decrease in metabolism from all doses

of I was less than in the 1 drop series. In the 13 cases that responded, the maximum reduction in basal metabolic rate appeared on the average in 7 days. In 4 cases a reduction occurred within 24 hrs. The daily oral administration of 3 mgm. of I in the form of compound solution of I is inadequate to produce a maximum reduction in basal metabolism in most cases of exophthalmic goiter in Boston, whereas 6 mgm. is adequate.—*Authors' summary.*

7170. **THOMPSON, WILLARD OWEN, ARCHIBALD C. COHEN, PHEBE K. THOMPSON, EDWARD G. THORP, and ALLEN G. BRAILEY. The range of effective iodine dosage in exophthalmic goiter. III. The effect on basal metabolism of the daily administration of one-quarter drop of compound solution of iodine and of slightly smaller doses, with a summary of results to date.** *Arch. Internal Med.* 45(3): 430-455. 1930.—During the daily administration of ¼ drop of compound sol. of I to 14 unselected hospital patients with exophthalmic goiter, 7 showed a reduction in basal metabolism of from 10 to 26 points, 6 showed no significant change and 1 showed an increase. During the administration of ¼ drop daily to 2 hospital patients with the disease, 1 showed a reduction of 14 points and the other showed no change. In the ¼ drop series, the basal metabolism was only slightly lower, and in the 2 hospital patients who received ⅛ drop, no lower during the subsequent administration of 30 drops a day, than during the administration of the small doses. Whereas only 50% of the patients showed a reduction in basal metabolism of 10 points or more during the daily administration of ¼ drop, 65% showed a reduction during the daily administration of ½ drop, and 88% during the daily administration of 1 drop. The administration of ¼ drop a day caused an average reduction in basal metabolism of only 9 points (from +43 to +34%) as compared with 14 points (from +40 to +26%) for ½ drop and 27 points (from +36 to +19%) for 1 drop. In the 7 patients who responded to ¼ drop, the maximum reduction in basal metabolism occurred on the average in 5 days. In 1 patient it had started within 24 hrs. In a series of outpatients, most of whom had the disease in a mild form, the daily administration of ⅛ drop produced an average reduction in basal metabolism of only 8 points (from +32 to +24%) as compared with 21 points (+32 to +11%) for 1 drop. Large doses given immediately after ⅛ drop caused a lowering of the metabolism to nearly the same level as 1 drop given initially in the 2nd series.—*Authors' summary.*

7171. **TIEMANN. Über die Erregung des Atemzentrums durch Salze niederer Fettsäuren (insbesondere Ketonkörper).** *Arch. Exp. Pathol. u. Pharmakol.* 148 (1/2): 102-110. 3 fig. 1930.—Salts of normal butyric acid and β-hydroxy butyric acid had an intense stimulating action on the respiratory center. This action was not dependent on their acid character. Normal valeric acid had a similar action. The respiration in animals poisoned by these drugs resembled that found in diabetes mellitus when ketosis occurs. The salts of acetoacetic acid, isobutyric acid and propionic acid had no effect on the respiratory center.

7172. **TRAUBE, J. Die Grenzflächenaktivitätstheorie (Haftintensitätstheorie, Oberflächenaktivitätstheorie) der Narkose.** *Pflüger's Arch. Ges. Physiol.* 218(5/6): 749-766. 1928.—Forces which determine the strength of narcotics are primarily surface forces. The amount of material adsorbed and the strength by which it is held largely determine the degree of narcosis. Narcotic action consists in inhibiting chemical, physical and especially bioelectrical phenomena. All these depend on adsorption. The intensity of adsorption of ions and non-electrolytes determines their narcotic action. Enzyme coagulation is essentially a surface phenomenon. The measurement of the surface tension of phase boundaries (fluid-fluid and solid-fluid) can be done only with great difficulty. The measurement of the surface tension between an aqueous solution and air is possible. Measurements of a series of solutions in which alcohols, ethers, esters, ketones, and fatty acids have been dissolved have been made. The surface activity of most of the alkyl halides is smaller than that required for narcosis. Adsorption equilibria of narcotics on silica gel and carbohydrates have been determined by Langmuir and Warburg and by Traube and Birutowitsch. The general theory of surface equilibria of these researches can be applied to the narcotic acid. The theory of Richet-Führer, which considers that narcotic action is dependent only on intensity of adsorption, holds for water soluble substances only. The work of Rehbinder and Okuneff showed that the surface activity theory could not replace the phase boundary theory. The observation of Winterstein and Höber, that narcotics in general decrease permeability, appears to be incorrect, or not to fall in line with the present theory. The significance of the stimulating effects of small amounts of narcotics is explained on physico-chemical principles by the theories of Arndt, Schulz, and Regel.

7173. **TRUFFI, GIOVANNI. Sulla alopecia da tallio. Il meccanismo d'azione del tallio nella produzione della alopecia nel bambino. [Alopecia from thallium. Mechanism of the action of thallium in the production of alopecia in the child.]** *Giornale Ital. Dermatol. e Sifilol.* 1: 3-23. 1 pl. 1928.—Histological examinations of the hair covered skin of children subjected to the action of Tl acetate in therapeutic doses were made a few hours after administration and at the time of falling and subsequent regeneration of the hair. Distinct lesions were demonstrated of the matrix of the hair and of the epithelial elements of the bulb, also of the root sheath and follicle sheath, lesions which produce falling of the hair. Most of the follicles produce new downy hair by regenerative action in about a month after administration of the drug. While this regeneration is verified, the deeper parts of some follicles undergo sclerosis. The lesions mentioned, probably due to direct action of Tl, are sufficient to explain the alopecia without recourse to intervention of the neuro-vegetative system.—*I. H. Pierce.*

7174. **ULRICH, HELMUTH. Synthalin-B in diabetes mellitus.** *New England Jour. Med.* 201(17): 814-816. 1929.—Each of 7 patients with diabetes mellitus received by mouth 40 mgm. synthalin-B (methyl guanidin) a day in 4 equal doses. The blood sugar was lowered in every case. The greatest drop was from 181 mgm. % to 100 mgm. %, the least from 235 mgm. % to 210 mgm. %. The effect became apparent in 1 or 2 days and usually persisted for several days after the drug was omitted. Two patients received 2 courses of treatment each, with intervening rest periods of 4 and 5 days, resp. Three patients experienced poisonous effects consisting of one or more of the following: nausea, vomiting, abdominal pain, diarrhea, headache. These symptoms vanished within 24 hrs. after the drug had been stopped. A smaller amount (30 mgm. per day) is recommended to lessen the toxic effects.—*H. Ulrich.*

7175. **VÁSÁRHELYI, JOHANN V. Experimente mit Thallium an stillenden Ratten.** *Dermatol. Wochenschr.* 87(45): 1741-1744. 5 fig. 1928.—Thallium given per os in rats, for 2 weeks after delivery, is secreted with the milk. The young show the characteristic symptoms of the Tl poisoning (hairless skin), whereas no effect of the Tl can be observed in the lactating animal. The increased toxic effect of Tl in young animals can be explained by the lability of their endocrine system. On the contrary the endocrine system of the adults is apparently more stable during the lactation period.—*J. V. Vásárhelyi.*

7176. **VESTERGAARD, J. D. E. Insulin and ocular tension. Observations on normal individuals, diabetics and glaucoma patients. (Preliminary report.)** *Acta Ophthalmol.* 7(3): 273-300. 1929.—Experimental procedure: Fasting patients were the subjects. Blood sugar was determined as usual; blood pressure and intraocular tension were read by means of Schiötz tonometer under holocaine anesthesia; the pulse rate was counted at intervals from 5 to 10 min. Twelve units of insulin were

then administered intraven. and the blood sugar, blood pressure, pulse rate and intraocular tension again determined at 5, 10 and 15 min. intervals. Control tests on patients with previous normal eye tension were made. The data are presented in 23 tables and 23 graphs. Results: *Normal individuals* showed an average fall of intraocular tension of 3.2 mm., or 17.5% of the original mean tension. This fall began 10 to 20 min. after injection of the insulin. The lowest tension was generally manifest before the blood sugar reached its minimum. It rose to normal in 65 min. *Diabetic patients*—one showed no change in the eye tension. The remaining patients of this group showed an eye tension change distinctly lower than those of the group of normals. *Glaucomatous patients* showed a slight fall in tension amounting to about 1 mm. in from 10 min. prior to 10 min. following the injection. Within the next 15 to 35 min. the fall reached 10.5 mm., or 30%. It then rose slightly and remained at a constant level for 5 hrs. *Effects of injection of adrenalin and hypophysin:* The effect of intraven. injection of adrenalin was too instantaneous for study. Results of subc. injection show that the fall of tension was apparently of the same type as that produced by insulin. Hypophysin (Hoechst —1 cc.) effected a fall of tension from 18 to 15 mm. in 10 min., and to 14 within 10 min. following. Within another 40 min. the eye tension regained its normal value.—*B. S. Levine.*

7177. VITTORIO, SUSANNA. Azione della colina sul sistema cardio-vasale. [Action of cholin on the cardiovascular system.] *Arch. Fisiol.* 28(3): 432-442. 9 fig. 1930.—Cholin produces a peripheral vasoconstriction, acting probably on the vascular smooth muscle. In animals with intact autonomic system it induces by vagal excitation a temporary fall of the arterial pressure, which however quickly returns to normal or above. In vagotomised and atropinised animals a constant increase of blood pressure follows the administration of cholin. —*M. Comel.*

7178. WATT, J. M. The pharmacology of Xysmalobinum. *Jour. Pharmacol. & Exp. Ther.* 38(3): 261-270. 1930.—Xysmalobinum, a crystalline glucoside isolated from the root of xysmalobium undulatum, R.Br., is toxic and produces a digitalis-like action on the heart. The degree of toxicity is low compared with other glucosides of similar action, and is less than that of a dry alcoholic extract of the root. The glucoside contracts the smooth muscle of the uterus, intestine, bladder and bronchi, the effect being especially marked in the bronchi. This last results in severe respiratory embarrassment which plays a part in the toxic action. The point of action in smooth muscle is peripheral to the nervous mechanism. The glucoside stimulates the secretion of saliva by stimulation of the terminations of the secretory nerves. A marked diuresis occurs in the rabbit.—*Author's summary.*

7179. WIGGERS, CARL J. Monophasic and deformed ventricular complexes resulting from surface applications of potassium salts. *Amer. Heart Jour.* 5(3): 346-350. 3 fig. 1930.—Concentrated KCl solution applied to the ventricular surfaces or injected into the pericardial sac in small quantities produced either monophasic or deformed ventricular complexes resembling those due to coronary occlusion. However, similar changes in the ventricular complex may occur from other influences. This observation represents the 1st crucial proof that drugs and chemicals can be absorbed from the ventricular surface of mammalian hearts.

7180. WILKINSON, JOHN F. Pernicious anaemia. Preliminary report on the results obtained by treatment with certain preparations of stomach. *Brit. Med. Jour.* 1(3604): 236-239. 1930.—Experiments, based on the possibility that pernicious anemia is a type of deficiency disease in which some essential factor is lacking in the gastric juice, were undertaken on 9 patients. The patients were divided into 3 groups, treated respectively with normal gastric juice, with raw fresh mucous membrane or muscular layer of hogs' stomachs, and with desiccated preparations of these 2 portions. The separate fractions were found equally potent, disposing of the argument that the efficiency of the treatment depends on the gastric pepsin. Clinical conditions, blood picture and reticulocyte count showed a response slightly more favorable than that obtained by liver therapy. Theoretical considerations are to be discussed and full details furnished later when other work has been completed.

7181. WINTER, J. E., C. H. RICHEY, and H. G. BARBOUR. Magnesium oxide as an aid to the antipyretic action of phenacetin in dogs. *Jour. Pharmacol. & Exp. Ther.* 38(3): 343-347. 1930.—Oral administration of phenacetin to dogs produces an antipyretic effect which is considerably enhanced by the addition of MgO. The results thus far obtained preclude final decision as to the presence or absence of synergism (i.e., potentiation as distinguished from simple summation); but they suggest trial of phenacetin fortified by Mg in the hope of securing equal therapeutic benefit, with less chance of poisoning.—*Authors' conclusions.*

7182. WISE, EDWIN C., and FREDERICK W. HEYL. A chemical study of urine as affected by combinations of ammonium chloride and methenamine. *Arch. Internal Med.* 44(2): 252-262. 1929.—Exps. on normal young men employed at light labor and fed a basic diet are reported in 3 series, each on 2 subjects. In the 1st series the subjects received daily doses of 0.97 gm. NH_4Cl and 0.49 gm. methenamine. In the other series the doses were larger. It was found that NH_4Cl, even against the high buffering effect of nearly neutral urine, produces a rapid acidifying effect, which at a level of 15 grains 5 times a day showed a pH of about 5.5. Methenamine at a level of 7½ grains 5 times a day gave a conc. somewhat but not proportionately lower than that found at the dosage of 15 grains. The acidity is of prime importance. In this work the dosage of methenamine varied from 37½ to 105 grains a day. The higher doses gave the higher conc. of formaldehyde, other factors being equal. NH_4Cl did not yield the maximum acidifying effect until the 2nd day. Following the last dose in the evening, the conc. of formaldehyde fell somewhat but usually became higher during the night, owing to the length of time the urine remained in the bladder. The sample taken at 6 a. m. usually had a high formaldehyde concentration, since most of the methenamine had been excreted during the night. There is a marked drop in the formaldehyde conc. in the forenoon, but it rises rapidly as the excretion of methenamine is increased following the medication.—*Authors' summary.*

7183. WOHLWILL, FRIEDRICH. Ueber eine Massenvergiftung durch Phosgengas in Hamburg. 2. Zur pathologischen Anatomie der Phosgenvergiftung. *Deutsche med. Wochenschr.* 54(37): 1553-1557. 3 fig. 1928.—Six autopsies were worked up from the phosgene catastrophe in Hamburg. Deviation from the previously communicated reports depended upon the fact that this time phosgene was at work, and not the so-called war gases. As to the main seat of morphological changes, the upper air passages were peculiarly exempt. There were injuries of the small bronchioles, the lung parenchyma, and the vessel walls, resulting in a marked impairment of the lesser circulation, with most of the significant changes in the other organs easily accountable. Contrary to the pharmacological literature, only part of the latter could be explained by immediate poisoning. Here belong degenerative changes in the liver, heart, and, especially, so far unobserved brain changes that could not be explained by simple circulatory disturbances. In a fatal case where death occurred 11½ days after the poisoning, thrombi in both ventricles with emboli in the left coronary artery were the immediate causes of death. There were interesting organizations in the lungs, also regenerative changes with corpora amylacea.—*F. Wohlwill* (*transl. by F. B. Flinn*).

7184. YAMAKAWA, K. Die Wirkung der arsenigen Säure auf das Ohr. [The action of arsenious acid upon the ear.] *Arch. Ohren-, Nasen- u. Kehlkopfheilk.* 123 (3/4): 238-296. 27 fig. 1929.—Arsenious acid sol. intro-

duced into the middle ear of rabbits or dogs produces the same symptoms as the extirpation of the labyrinth. The microscopic changes of the middle ear consist of secretions and exudative processes, of damage to the vessels and of edema, swelling and finally of necrosis of the mucous membrane. The pathologic changes in the labyrinth comprise 3 groups: 1st, a reactive hypersecretion, 2nd, pathologic changes like fibrinous labyrinthitis in human beings. The third group consists in hemorrhages and necrotic processes. The clinical as well as the anatomical changes are always the same at varying concentrations of the poison, but they begin sooner with higher concentrations. The possibility that certain high dilutions may kill the most sensitive portions of the labyrinth can often be of certain advantage. The conception of Wittmarcks that hydrops is an important factor in the dissolution of necrosis was confirmed. The consequences of the action of arsenic on the ear are identically the same as those of inflammatory necrosis of the labyrinth.—*F. R. Greenbaum.*

7185. **YAMAUCHI, MASASHI. Über die periphere Wirkung des Yohimbins.** *Okayama Igaku Kwai Zasshi* 39: 1890-1893. 1927.—By action on the smooth muscle, in small doses it generally stimulates isolated surviving organs of the rabbit, such as uterus, tubes, ligamentum rotundum, vagina, bladder, and vessels of the ear. Epinephrine checks or removes the stimulating effect and its own stimulation is counteracted by yohimbine, a phenomenon explained in paralysis of the accelerator fibers of the sympathetics by yohimbine without effect on the inhibitor mechanism. The smooth muscle and parasympathetic nerves are not paralyzed, since the stimulating actions of Ba and pilocarpine are not checked. Yohimbine is, therefore, similar to atropine, quinine and ergotoxine, but the action is much more distinct with yohimbine, because the muscular paralysis is much weaker than from quinine and because, unlike atropine, there is no action on the parasympathetics. The drug represents an important means for pharmacological and physiological investigation, because it easily permits distinguishing sympathetic action of any poison, and also makes possible the exclusion of sympathetic accelerator fibers.—*Author (courtesy Japanese Jour. Med. Sci. IV) (transl. by E. V. Lynn).*

7186. **YOSIMOTO, MASARU. Die Einflüsse des Traubenzuckers auf die Leukozyten.** (Japanese.) *Juzenkwai Zasshi* 31(10): pp. ? 1926.—Glucose (intraven.) in rabbits caused the leucocytes to increase, especially the eosinophils. Their count later returned to normal. Their increase is definitely related to that of the blood platelets.—*O. Mori (courtesy Japanese Jour. Zool.).*

7187. **YOSOMIYA, RYŪZŌ. Experimentelle Studien über die Einflüsse verschiedener Pharmaka auf die durch progressive Sauerstoffverdünnung entstehenden physiologischen Reaktionen. III. Über die Einflüsse der Inkrete und der vegetativen Nervengifte. [Influence of different drugs on the physiological reactions due to progressive lowering of O concentration. III. Effect of autacoids and nerve poisons.]** *Tohoku Jour. Exp. Med. [Sendai]* 9(2/3): 229-250. 5 fig. 1927.

7188. **YOUMANS, JOHN B., and W. H. TRIMBLE. Experimental and clinical studies of ergotamine. I. Effect of ergotamine on the blood sugar and epinephrine hyperglycemia in trained unanesthetized dogs.** *Jour. Pharmacol. & Exp. Ther.* 38(1): 121-132. 1930.—Ergotamine tartrate intraven. (0.125 to 0.5 mgm. per animal), caused no consistent change in the blood sugar level of trained, unanesthetized, normal dogs. Both a rise and a fall of blood sugar was observed at different times but in half the experiments no significant change occurred. The action of ergotamine was not modified by atropine. Ergotamine (0.25 to 0.5 mgm. per animal intraven., or 0.5 to 1.0 mgm. subc.), failed to prevent or diminish the hyperglycemia caused by the intraven. injection of epinephrine in these dogs. It seems unlikely that ergotamine in doses which can be safely employed in exps. on man can significantly influence those functions of the sympathetic which may be concerned with the maintenance of blood sugar levels or the hyperglycemic action of epinephrine.—*Authors' summary and conclusions.*

7189. **ZEISS, F. R., and WILLIAM A. BRAMS. Studies on the effect of nitroglycerin, amyl nitrite and acetylcholine on hypertension.** *Amer. Heart Jour.* 5(3): 300-304. 1930.—A series of patients with hypertension and renal involvement were given nitroglycerin, amyl nitrite, and acetylcholine after the blood pressure had been reduced to a fixed level by bed rest, diet, and limitation of fluid intake. The results were controlled by a study of a similar series of normal persons. Nitroglycerin, gr. 1/50, under the tongue, produced a fall in blood pressure in all the normal controls, but this effect was inconstant in the patients with hypertension. Amyl nitrite caused a fall in pressure in the controls and hypertensive cases in every instance, being effective also in those instances where nitroglycerin failed to act. A reaction in the form of a temporary rise to a level above that existing before the administration of the drug occurred in a large proportion of the cases with hypertension receiving amyl nitrite or nitroglycerin. The control cases receiving nitroglycerin showed a similar reaction rise, but not after amyl nitrite. This rise may be of some clinical value in cases of impending or actual cerebral hemorrhage. The effect of amyl nitrite in the doses used was much more marked and lasted almost as long as that of nitroglycerin but headache, vertigo, and flushing were more marked after the former drug. Acetylcholine was found to be inert in both the controls and the cases of hypertension, in contradistinction to the claims made in the literature.—*Authors' summary.*

7190. **ZUNZ, EDGARD. Elements de pharmacodynamie générale.** 465p. 82 fig. Masson et Cie: Paris, 1930. 75 fr.—This is a compilation of existing information concerning the physical, chemical, physico-chemical, and physiological factors which underlie the action of drugs. There are 22 chapters, the titles of some of which may give an idea of the unique scope of the book: modifications of drugs in the organism; modifications of the blood by drugs; effects upon internal secretions; upon external secretions; synergisms; antidotisms and antagonisms; inversions; relation of chemical composition to physiological effect; modes of action; biological assays. A bibliography is appended to each chapter, and a complete one at the end of the book. Unusual features in a work on pharmacology are discussions of the laws of osmosis and diffusion and the Donnan equilibrium in relation to the absorption of drugs; of the factors concerned in regulating the reaction of the blood; the effects of drugs upon erythrocyte and leucocyte counts and upon phagocytosis; the influence of O upon chemotaxis of leucocytes; the regulation of the secretion of epinephrine. Structural formulae are used liberally and effectively. The chapter on bio-assays gives a brief account of the recent developments in international standardization of drugs, and the last chapter is an epitome of the methods and procedures of pharmacologic investigation. Such topics as theories of narcosis and the newer electro-physiology of nerve and muscle are omitted. The material is presented here in concise, categorical fashion. The author's interpretation of the material is uncritical, for the most part. The book serves to emphasize the descriptive, centrifugal nature of most of the information available to the pharmacologist, and the need for centripetal information concerning the mode of reaction of drug with tissue substance.—*C. F. Schmidt.*

ANIMAL PATHOLOGY

7196. **SCHWARZ, OSWALD. Medizinische Anthropologie. Eine wissenschaftstheoretische Grundlegung der Medizin.** 383p. S. Hirzel: Leipzig, 1929. Pr. 13 M.—This is a work in philosophy. It deals with anthropology and medicine from a purely theoretic viewpoint and hence will appeal chiefly to those who are interested in a systematic development of ideas in the science of man. The public to whom it is addressed is dual, philosophers and physicians; and this lack of homogeneity in audience introduces the difficulty (well recognized by the author) of keeping the presentation understandable for one type of reader without becoming banal for the other. The first part is devoted to the presentation of fundamental concepts in anthropology proper and, in addition to its own inherent value, serves as a background in which is set the more distinctively medical theory which forms the closing part. Anthropology is considered the fundamental medical discipline; and after an initial chapter in which the concept of a medical anthropology is developed, the author proceeds to unfold his thought under the headings, "Man as Part of Nature," "Man as Creator of Culture," and "Man as Member of a Community." This first portion ends with a consideration of the position of anthropology in the system of sciences. In the more medical part are discussed: first, the fundamental concepts of medical anthropology—"type," "norm," "sick"; and then concepts of medicine itself such as "disease" and "therapy." In the handling of "disease," especially, are presented ideas of importance to every physician, for under this caption will be found the discussions of "etiology," "symptoms," "diagnosis," etc. The work ends with a chapter on the intellectual currents in the medicine of today in which are outlined the steps which have led to the "Personalismus" characteristic of modern medical thought, and in which is traced the development of the concept of disease from "Organpathologie," through "Konstitutions-pathologie," to a "Pathologie der Person." There is a bibliography limited, however, almost exclusively to German references.—*W. D. Inlow.*

ANIMAL PATHOLOGY

MORBID ANATOMY

E. W. GOODPASTURE, *Editor*

C. EUGENE WOODRUFF, *Assistant Editor*

(See also in this issue Entries 6220, 6229, 6234, 6236, 6237, 6249, 6697, 6911, 6950, 7183, 7193, 7259, 7266, 7281, 7295, 7323, 7356, 7390, 7532, 7542, 7570, 7581, 7582, 7638, 8255, 8271, 8299, 8300, 8301, 8306, 8311, 8324, 8326, 8336, 8343, 8352, 8358, 8364, 8374, 8392, 8412, 8417, 8420, 8951)

7197. **AGRIFOGLIO, MARIO. Ricerche sperimentali sulla dilatazione diffusa dell'esofago.** [Experimental diffuse dilatation of the oesophagus.] *Arch. Ital. Chir.* 28(4): 337-360. 32 fig. 1931.—The first results of denervation of the cardia in 8 dogs was ectasia and atony of the oesophagus, while in most cases the tonus of the cardia was perfectly preserved. Later the oesophagus became dilated and oesophageal peristalsis reappeared, though shallow and slow. In a few cases x-ray showed oesophageal atony extending to the cardial tract. Histologically a slight thickening of the oesophageal wall and sometimes of the submucous connective tissue was apparent; sometimes the mucosa seemed like a thin uniform layer. The cardia was normal except when ulcerative lesions were present.

7198. **ANDREI, ORESTE. Sulle cisti, o gangli, così detti sinoviali.** [So-called synovial cysts or ganglia.] *Chir. Organi Movimento* 15(3): 187-265. 8 fig. 1931.—The author examined the hands of 7 fetuses (3-8 months) and of 4 adult subjects without finding "subsynovial bodies" or "synoviparous follicles" such as reported by Gosselin and others. He reports 15 experiments on dogs, rabbits and a cat in which he attempted, with uniformly negative results, to produce synovial cysts or ganglia by contusions, isolation of the tendon sheath and introduction into it of foreign bodies, injection into the joint or the tendon sheath of mechanical or chemical irritants, and injection into the synovia of a suspension of killed tubercle bacilli. From these observations and from 7 clinical cases described he concludes that so called synovial ganglia or cysts are usually the expression of a dropsical degeneration sui generis of the connective tissue especially around the joints and tendons, and are not to be ascribed to any specific etiological agent.

7199. **ARMENTROUT, AUBREY WEBSTER. Embolism and thrombosis: prolonged direct observation of the phenomena in pial vessels of the living cat.** *Arch. Path.* 11(4): 519-545. 12 fig. 1931.—Emboli in the pia were observed in 37 living cats (18 with various kinds of fat, 10 with charcoal, 3 with emery, 1 with powdered glass and 5 with blood clot), the animal being anesthetized and the field exposed for microscopic observation through a specially designed glass window. Fat droplets in the arteries of the pia, in the vast majority of instances, completely blocked the vessels in which they lodged. White thrombi formed on fat droplets, but to a less degree than

on other types of foreign bodies. The thrombi produced by rough and irregular pieces of charcoal were frequently insufficient to block the blood vessels in which they lodged, even when present over a long period of time and when there was marked slowing of the blood stream. Sharp substances (emery and powdered glass) produced extensive thrombosis, and death in a short time. Contrary to the author's expectations, blood clot emboli, moist, dry or highly contaminated, did not produce obstructive thrombosis, in some instances, when observed as long as 96 hrs. After numerous repeated injections of small amounts of air, the pial circulation remained apparently uninjured. There were no hemorrhages in relation to emboli of any nature in periods of observations as long as 96 hrs., irrespective of complete or incomplete vascular occlusion. The author concludes that following embolism in the cat the first reaction is the separation of the foreign body, no matter what its nature, from the blood stream by a collection of platelets, an extremely friable "white thrombus," the formation of which practically ceases when the foreign body has been separated from the blood stream. If the endothelium has been injured by the foreign body, progressive thrombosis occurs. The distinction between these 2 processes probably lies in the freeing of thromboplastic substances in the latter instance. When progressive thrombosis does not occur, the external surface of the white thrombus is apparently entirely bland, so that the blood continues for many hours to flow past the obstruction, even when the space between the embolus and the opposite vascular wall barely admits a single erythrocyte. The effect of slowing of the blood current on this process—namely, the exteriorization of foreign bodies from the active blood current—is not perceptible. If not originally large enough to occlude the blood vessel, the white thrombus, in general, does not grow large enough to do so, even in the presence of a falling blood stream or when bathed in blood that flows only intermittently. This last observation is contrary to all previously reported opinions. In the pia, no perivascular reaction to vascular occlusion can be observed.

7200. **ATKIN, E. E. Primary carcinoma of bronchus.** *Jour. Path. and Bact.* 34(3) : 343-348. 1931.—The histological type of bronchial carcinoma is correlated with the age of the patient; the age is greater when the carcinoma is a squamous-celled one. All the growths showing definite cavitation after death were squamous-celled, and all the examples of secondary deposits in the opposite lung were in this type of carcinoma.—*E. E. Atkin.*

7201. **BARNARD, W. G., and F. M. R. WALSHE. Capillary haemangeioma of cerebrum.** *Jour. Path. and Bact.* 34(3) : 385-387. 1931.—This rare tumor, in a woman aged 47 yrs., was definitely in the cerebrum and is believed to be a true tumor.—*W. G. Barnard.*

7202. **BARNARD, W. G. Multiple teratomata of peritoneum.** *Jour. Path. and Bact.* 34(3) : 389-391. 1931.—More than 100 small solid and cystic masses of growth on all parts of the peritoneum and larger masses in the omentum proved to be teratomatous, nervous tissue being especially abundant, and were associated with a teratomatous cyst of the left ovary. The patient was a married woman 40 yrs. of age who had suffered from swelling of the abdomen and discomfort due to ascites for 3 mos.—*W. G. Barnard.*

7203. **BAUER, K. H. Über Selbstzertrümmerung von Gallensteinen und Neubildung von Steinen auf der Grundlage von Steintrümmern. [Spontaneous crumbling of gallstones and formation of new stones about the fragments.]** *Arch. Klin. Chir.* 165(1) : 53-80. 21 fig. 1931.

7205. **BORLAND, V. G., and C. M. JACKSON. Effects of a fat-free diet on the structure of the kidney in rats.** *Arch. Path.* 11(5) : 687-708. 5 fig. 1931.—Rats (124) were divided into 10 groups, including 3 groups of test rats (42), 2 groups of cured rats (44) and 5 groups of control rats (38). Characteristic renal lesions were demonstrated in the rats reared on Burr's highly purified diets, which are practically fat-free but otherwise adequate. The most striking and characteristic renal lesion was the calcification in the cells of some renal tubules and in necrotic areas of the renal medulla. In extreme cases there was complete disintegration of the apical region of the pyramid. Various forms of renal epithelial degeneration and fatty or lipoidal changes also occurred to a variable extent, sometimes associated with the calcification, sometimes not. In the medulla, large quantities of fatty or albuminous material sometimes accumulated, forming casts in the lumina of the tubules and especially in the papillary ducts. An atypical (uncornified) hyperplasia was often found in the renal pelvic epithelium, usually most pronounced where necrosis of the papilla was also present. Slight focal infiltration by round cells was found in the test rats, but no more frequently than in the normal controls. The inclusion bodies incidentally noted in the cortical epithelium of some of the controls apparently had no relation to the disorder caused by a deficiency of fat in the diet. The addition of 2-20% of lard, or of slight amounts of cod liver oil, to the diet usually prevented or cured the renal disorder, at least to a large extent, almost completely eliminating the calcareous degeneration and casts. Various other types of fat (corn oil, olive oil and methyl linolate) usually appeared somewhat less beneficial to the kidney, in which some of the lesions persisted, although the general condition of the body was cured or greatly improved. The concentration of dietary protein, within the range used, showed no definite relation to the incidence or to the severity of the renal lesions observed.

7207. **CUMMINS, S. L., and A. F. SLADDEN. Coal-miner's lung.** *Jour. Path. and Bact.* 33(4) : 1095-1132. 5 pl. 1930.—Chemical and pathologic examination of the lungs of 32 Welsh coal-miners and 6 controls showed that the black material present consisted chiefly of coal-dust, retained because the high silica content of the lungs had damaged and blocked the lymph channels, thus impairing the normal power of the lungs to dispose of inhaled dust. Fe was not an important constituent. This refutes Jousset's contention that the black pigment is of endogenous origin and that anthracosis should be called siderosis.—*S. L. Cummins.*

7208. **DIETERICH, HANS. Die Regeneration des Meniscus.** *Deutsche Zeitschr. Chir.* 230(3/5) : 251-260. 4 fig. 1931.—The regenerates, examined 11, 18, and 28 days and 2, 3½, and 4½ mos. after partial resection of the meniscus in 6 dogs, were morphologically incomplete, the defects being replaced by tendon-like cicatricial tissue, not by cartilage. When the course was associated with synovitis proliferans the prognosis for joint mechanism was poor. In relatively rare cases the regenerate can approximate the form of the normal meniscus.

7209. **DURANTE, G. Vagabondage cellulaire.** *Soc. Med. Hôp. Paris.* 52(16) : 758-761. 1928; also *La Presse Médicale* 36(51) : 808-811. 1928.—Parenchymatous cells are frequently present in the blood vessels of various organs. In the vessels of the liver, hepatic cells, renal and intestinal epithelium and other unidentified cells were found. Similarly in the renal vessels, epithelium of the Henle's tubules and smooth muscle cells were observed. There is a system of wide vessels in the kidney formed by a single layer of endothelium in which the desquamation of the fixed parenchymatous cells and their delivery to the blood stream takes place. This process occurs in normal and in diseased organs and fol-

lows sudden changes in blood pressure.—*C. Durante (transl. by J. Furth).*

7210. **FELDMAN, WILLIAM H. The histology of experimental tuberculosis in different species. A comparative study.** *Arch. Path.* 11(6): 856-913. 11 fig. 1931.—Infection with pure human, bovine, and avian strains of *Mycobacterium tuberculosis* was induced in chickens, rabbits, guinea pigs and dogs (no. not stated). The lesions varied, not with the type of infecting organism, but with "certain indefinite factors" characteristic of the species to which the infected animal belonged.

7211. **GERSTEL, GUSTAV. Zur Kenntnis der Graviditas superficialis ovarii und ihrer klinisch-histologischen Diagnose.** *Virchow's Arch. Path. Anat. u. Physiol.* 280 (2): 435-443. 3 fig. 1931.—In a case of extrauterine pregnancy there were chorionic residues on the outer surface of a hemorrhagic mass in the ovary; they contained ectoblast, Langhans' cells, syncytium, and chorio-epithelial migratory cells. The actual ovary and corpus luteum were entirely free of chorionic material.

7212. **GOUGH, J. Mitochondrial changes in experimental oxalate and uranium nephritis.** *Jour. Path. and Bact.* 34(4): 423-428. 1 pl. 1931.—With the method of Gough and Fulton for the demonstration of mitochondria, intravenous injections of Na oxalate and uranium acetate into rabbits produced morphological changes in the mitochondria of the renal epithelium within a few minutes of the injection. In oxalate poisoning, the changes consisted of granulation and fusion of the mitochondria and reached their maximum extent within ½ hour of the injection. In cases where small dosage of the poison had been used, resolution subsequently occurred in most of the affected cells. In uranium poisoning, replacement of the mitochondrial filaments by large, scattered, spherical bodies was characteristic. This change was indicative of more severe and permanent cell degeneration.—*J. Gough.*

7213. **GOLDSTEIN, DN., und P. NIKIFOROV. Über die sogenannte Kaschin-Beckschе Krankheit. (Eine röntgenologische und klinische Studie.) [Kaschin-Beck's disease.]** *Fortschr. Geb. Röntgenstrahlen* 43(3): 321-336. 25 fig. 1931.—The author reports a family in which the father was affected at 5 yrs., oldest son at 3 yrs., and 5th child, ♂, at 3½ yrs.; the 4th child, ♀, was affected before death at 2 yrs.; 2 boys died at 7 yrs. and 6 mos. respectively without signs of disease. There was no family history of the disease. The disease is characterized by polyarticular, symmetrical deformities of the joints of the extremities; in these cases the spine and skull were also involved. While usually appearing in the 5th yr. it has been found in the newborn and embryos; it is apparently correlated with disturbances of the incretory glands, particularly thyroid. Mentality and nervous system are usually little affected. Roentgenographically, the disease belongs to the osteochondroarthroses.

7214. **HEINE, L. Über die Vielgestaltigkeit (Polymorphismus) und Kriechbewegung (Amöboismus) der Sarkomzellen, sowie über 12 Fälle von kleinsten Sarkomen und sarköser Entartung der Aderhaut. [Polymorphism and amoeboidism of sarcoma cells; also 12 cases of very small sarcomata and sarcous degeneration of the choroid.]** *Virchow's Arch. Path. Anat. u. Physiol.* 280(1): 122-135. 11 fig. 1931.

7215. **HURST, E. W. The occurrence of intranuclear inclusions in the nerve cells in poliomyelitis.** *Jour. Path. and Bact.* 34(3): 331-334. 1931.—In the nuclei of degenerating nerve cells in cases of monkey and human poliomyelitis, multiple small rounded bodies were stained electively by phloxin-methylene blue and giemsa. They were found in the anterior-horn and other cells of the spinal cord in the brain-stem and in the Betz cells of the motor cortex. Most numerous on the first day of the disease, they were difficult to find later and were never seen in completely necrotic cells or in masses of debris undergoing neuronophagia. They were never seen in normal nerve cells or in glial cells, or during the incubation period or in controls. They appear to be nuclear inclusions of the same order as those in herpetic encephalitis and Borna disease.—*E. W. Hurst.*

7216. **KING, E. S. J. Malignant phaeochromocytoma of the adrenals.** *Jour. Path. and Bact.* 34(4): 447-452. 2 pl. 1931.—In a hitherto undescribed form of phaeochromocytoma of the adrenals the growths were solid and bilateral. Cells of 2 types were present: typical phaeochrome cells and anaplastic cells not giving the typical chrome stain but showing all transitions from the typical cells. The multiple metastases in the liver, lungs, bones, skin and aortic glands, usually had the same structure as the anaplastic areas of the adrenals, but some showed both this and typical phaeochrome tissue.—*M. J. S.*

7217. **LASNITZKI, A. Über die Regeneration des Hautepithels bei vermindertem Luftdruck.** *Virchow's Arch. Path. Anat. u. Physiol.* 281(1): 66-72. 8 fig. 1931.—Four burns 1 cm. long were made in the skin of each of 4 guinea pigs; 5 scalpel incisions deep enough to produce capillary hemorrhages and some stab wounds made with an 0.5 mm., glowing platinum needle were made in each of 5 others; 2 of the first group and 3 of the second were placed under decreased pressure of 335 mm. Hg (experiments done at Davos = 125 mm. Hg decreased pressure). Two of each group died in 6-7 days and the controls were killed at the same time; the other died at the end of 2 days. Another set of controls was kept in Berlin at sea level. Regeneration of skin at 335 mm. Hg occurred exactly as in normal atmospheric pressure.

7218. **LENZ, ROBERT. Zur Frage der rheumatischen Chorea. (Mit einem Beitrag zur Histopathologie der Chorea und zur Nirvanol-Behandlung.)** *Wien. Arch. Inn. Med.* 21(1): 95-126. 5 fig. 1931.—Investigations were made on 27 patients with rheumatic chorea (8 treated without success) and necropsy obtained in 2. Degenerative alterations were found in the small ganglion cells of the striatum with occasional injury to some elements of the large cells, and in the ganglion cells of the hypothalamic nucleus; inflammatory changes, either acute or chronic, were present in the vessels and their immediate neighborhood. Rheumatic nodules were found in the heart. Nirvanol inhibited the stimuli passing to the large cells of the striatum, the effective dose lying near the toxic. Nirvanol sickness appeared to be caused by toxic decomposition of protein.

7219. **MAGALHÃES, AGGEU de GODOY. The kidneys in yellow fever.** *Arch. Path.* 11(4): 561-573. 1931.—Material from 87 patients with yellow fever and from 34 monkeys (*Macacus rhesus*) experimentally infected with yellow fever was used. Of the cases in man, 53 occurred in West Africa and 34 in South America; all the experimental animals had been infected with West African virus. The kidneys were severely and characteristically injured. The convoluted tubes were dilated, and their cells swollen, undergoing intense hyaline and granular degeneration. There was necrosis of some cells in the various structures; the glomeruli, with their tufts, were engorged; the capsular space was dilated. The cells of the epithelial covering of Bowman's capsule were necrotic and desquamating; there was granular material or debris in the interior of a great number of convoluted tubes; hyaline, granular, and calcareous casts occupied the lumina of some convoluted tubules, of Henle's loops or of the collecting tubules. Congestion of the small vessels was most marked in the medullary zone. There was neither hemorrhage nor inflammation. Fatty degeneration played a minor rôle in the ensemble of degenerative changes in most cases. The calcareous casts contained Fe. Some of the nuclei of the degenerating cells contained acidophil, homogeneous, hyaline inclusions, sharply isolated in an empty, clear space. Other nuclei showed some form of degeneration as manifested by their solidification into acidophil, compact, hyaline masses, breaking up afterward into innumerable granules which tended to lose their color and gradually to become fused with the mass of protoplasm, which in such cases was always undergoing hyaline and granular disintegration.

7220. **MELINA, F. Actinomicosi sperimentale del fegato e sistema reticolo-endoteliale. [Experimental actinomycosis of the liver, and the reticulo-endothelial system.]** *Arch. Ital. Chir.* 28(1): 1-33. 19 fig. 1931.—The liver was infected with *Actinomyces asteroides eppingeri* in 16 guinea pigs, of which 8 had not had previous treatment, while 8 had previously had the reticulo-endothelial system (R. E. S.) blocked with trypan blue. The liver was directly infected in 4 of each series; in the other 4 the infection reached the liver by way of a branch of the mesenteric vein. Both methods produced infection. The nodules in the liver were at first predominantly exudative, later proliferative, going on to a cicatricial phase. The organism was often found even in the center of the nodules, in the mass of leucocytes, under various forms, usually radiating, with terminal clubs; it could be obtained by back culture, but with difficulty when the granuloma was already in advanced fibrous evolution. Trypan blue in vitro (1 drop of 1% solution to about 2 cc. of medium) did not inhibit the growth of the culture, nor did vital staining hinder the infection of the liver. The so-called block of the R. E. S. did not hamper the normal processes of defense and repair, but in the foci of infection the leucocytes were the first line of defense, and only later did the elements of the R. E. S. come into play. In the formed actinomycotic granuloma of the liver, the cells of the R. E. S. (mostly voluminous, some giant polymorphonuclears, stuffed with dye granules) occupied chiefly the middle zone (where they were phagocytic) and periphery (where they were fibroblastic). The elements of the R. E. S. in hepatic actinomycosis are furnished chiefly by the elements of the interstitial tissue of the region in which the phlogistic process occurs, and probably in less degree of the contiguous regions; all these elements develop consequently great activity, particularly phagocytic and histocytic.

7221. **MINDER, JULIUS. Über die Hydronephrose auf Grund klinischer und experimenteller Erfahrungen.** *Zeitschr. Urol. Chir.* 31(5/6): 173-192. 21 fig. 1931.—Various portions of the bladder and ureter in 29 rabbits and 7 dogs were treated externally with applications of paraffin or cerumen, the ureter being patent or occluded with paraffin or a drainage tube. Various portions of some ureters were denuded (usually surgically, also chemically) and the effect of mechanical obstruction at a distance therefrom observed. Undoubtedly the anatomical condition of the ureteral wall is of significance in the development of hydronephrosis, since denudation alone was sufficient to produce it, though it occurred more rapidly when mechanical obstruction was also present.

7222. **MOURIQUAND, G., J. ROLLET, et Mme. CHAIX. Etude biomicroscopique et histologique des lésions cornéennes dans l'avitaminose A. Les stades initiaux de la xerophtalmie.** *Bull. Histol. Appl. Physiol. et Path.* 8(3): 72-83. 4 fig. 1931.—The first corneal change is an edema resulting in loss of transparency. Carried to the point where the epithelium and edematous tissues slough, infection enters and ulceration follows. The early phenomena cannot be determined from histological preparations only.—*J. G. Sinclair.*

7223. **MUIR, R. Further note on Paget's disease of the nipple.** *Jour. Path. and Bact.* 34(4): 594-595. 1931. —Confirms the previous view that Paget's disease is due to the invasion of the epidermis by a carcinoma arising in the ducts.—*A. E. Boycott.*

7224. **NORDGREN, BO. A case of agranulocytosis with intestinal changes.** *Jour. Path. and Bact.* 34(3): 379-384. 1931.—A case of agranulocytosis with death from ulcerous and necrotic enteritis is reported. It is concluded that in these cases the septicemia (and local necrotic lesions) is the result and not the cause of the defect in the granulopoietic system.—*M. J. S.*

7225. **PESCATORI, FRANCESCO. Contributo istopatologico allo studio della morfologia e patogenesi dei corpi ialini nei tessuti. [Morphology and pathogenesis of hyaline bodies in tissues.]** *Lo Sperimentale* 85(1): 1 pl. 25-52. 1931.—After a histopathologic study of such conditions as ulcerating neoplasms, gastric ulcers and granulomata, the author concludes that all hyaline bodies do not arise as simple degeneration products within such elements as plasma cells and eosinophiles, and he accepts the earlier concept of Lubarsch that they owe their genesis mainly to local metabolic disturbances (e.g., compression, and vascular stasis) in the tissues.—*M. L. Menten.*

7226. **PESSIN, S. B. The enterochromo-argentaffin cells.** *Arch. Path.* 11(2): 171-189. 9 fig. 1931.—The part played by argentaffin cells in inflammatory processes, especially of the appendix and the intestinal tract in general, was studied in 66 appendices removed at operation, in tissues from all portions of the gastro-intestinal tract (including the appendix), and in the pancreas, suprarenals, paraganglionic tissue and hypophysis from 45 necropsies, and also in the duodenum of the rabbit and of the guinea pig. The author draws no definite conclusions concerning the pathologic significance of the argentaffin cells; but he calls attention to the fact that the Kultschitzky-Schmidt-Ciaccio cells are the same as the chromo-argentaffin cells of Masson. He concludes that the glandular argentaffin cells specifically belong to the intestinal tract and may be termed enterochromo-argentaffin cells. The periglandular argentaffin cells are morphologically so variable and their origin is so uncertain that no definite classification is possible at present.

7227. **PETRI, ELSE. Pathologische Anatomie und Histologie der Vergiftungen. [Pathologic anatomy and histology of poisoning.]** 724p. 96 fig. Julius Springer: Berlin, 1930. Pr. 144 M.

7228. **POLICARD, A., et JACQUES ROLLET. Réactions du tissu cornéen vis-à-vis des particules minérales siliceuses.** *Bull. Histol. Appl. Physiol. et Path.* 8(2): 52-58. 1 fig. 1931.—The cornea is non-vascular and injection of the silica dust in fine suspension causes no inflammation. Capillaries at the corneal border congest and there is some edema with recovery. There follows a very slow connective tissue degenerative action demonstrating a mild toxicity of the dust.—*J. G. Sinclair.*

7229. **RAVAULT, PIERRE P., et C. BOUYSSET. Les lésions des artères dans la gangrène diabétique.** *Bull. Histol. Appl. Physiol. et Path.* 8(1): 5-20. 4 fig. 1931. —In diabetic gangrene in contrast with thrombosis or other circulatory interference, the part remains at body temperature or warmer and shows a capillary pulse. The arterial defects follow the nutritional instability of the tissues as an accident of infectious or inflammatory nature. The result is edema and hyperplasia of the intima with cholesterin deposits and calcification of the media.—*J. G. Sinclair.*

7230. **ROTTER, WERNER. Über die histologischen Veränderungen des Dünndarms bei Ankylostomiasis. [Histological changes in the small intestine in ancylostomiasis.]** *Virchow's Arch. Path. Anat. u. Physiol.* 280 (3): 587-594. 8 fig. 1931.—A detailed description, based on a large no. of cases, of the 2 types of injuries (hemorrhages from bites and conditions subsequent to them, and chronic enteritis) is given.

7231. **SALLMANN, L. Zum histologischen Bild der Goldspeicherung in der menschlichen Hornhaut nach Tätowierung. [Histology of gold storage in the human cornea after tattooing.]** *Graefe's Arch. Ophthalmol.* 126 (1/2): 297-303. 1 fig. (col.) 1931.

7232. **SCHULTHEIS, THEODOR. Histologische Untersuchungen an Steinnieren.** *Zeitschr. Urol. Chir.* 31 (5/6): 193-230. 20 fig. 1931.—There is always pyelitis varying according to the size of the concretion, the functional disturbance elicited, and the infection. Glomerulo-tubular nephritis with a more atrophic tendency was found in the aseptic kidneys; it had a strongly inflammatory component in the infected kidneys. The interstitial tissue was sometimes edematous, sometimes hypertrophic. Occasionally intrarenal sclerosis of an artery was observed. Finally, there was a relatively

slight inflammatory participation of the fibrous and of the adipose capsule.—*Author's summary (transl.)*.

7233. **SNIJDERS, E. P., und J. E. DINGER. Die pathologisch-anatomische Diagnose des Gelbfiebers bei Affen.** *Virchow's Arch. Path. Anat. u. Physiol.* 280(2): 444-462. 17 fig. 1931.—Necropses were performed on 76 [*Macacus*] *rhesus*, 16 *M. cynomolgus*, and 1 *M. nemestrinus* monkeys that had died of yellow fever, 5 *rhesus* in which diagnosis was doubtful, 20 *rhesus* and 3 *cynomolgus* controls. Only the hepatic changes were sufficiently characteristic to be of value. While Torres inclusions were of diagnostic value it was very doubtful that they were indicative of the presence of the virus in the nucleus. Rather, it appeared that nuclear degeneration occurred because of the virus. Serum of 6 persons with dengue was injected into *rhesus* monkeys; 3 received 14 cc. of 1:4 dilution of serum and 0.5 cc. of infectious blood from yellow fever monkeys; 1 control received the same amount of virus and normal serum; 3 received 4, 3.5, and 2 cc. of 1:4 dilution and 2 hrs. later were bitten by the yellow fever mosquito. All developed yellow fever. Serum of dengue, thus, exerts no protective action against yellow fever; such an action had seemed probable since the two fevers had a similar course.

7234. **STEWART, T. D. Dental caries in Peruvian skulls.** *Amer. Jour. Phys. Anthrop.* 15(2): 315-326. 1931.—An adequate racial study of dental caries should consider the relative susceptibility of the surfaces of the individual tooth forms of both jaws, controlled as to age and sex. In 100 Peruvian skulls of each sex, within the age period between closure of the basilar suture and beginning closure of the sagittal, the relative antemortem loss (assumed to be due to dental caries) of each tooth form was determined. Age determinations are not sufficiently accurate in the skull to delimit older age groups; besides, alveoloclasia and attrition later complicate the antemortem loss. For comparison, the antemortem loss in 100 older Peruvian skulls of each sex is given. Teeth of the ♀♀ were more carious than those of the ♂♂. Maxillary teeth were more carious than mandibular. The first molar was not as susceptible to caries as the second and third, but probably became equally susceptible at a later age. Observations on the teeth present showed that caries attacked the tooth below the enamel line on the cervix and through developmental defects in the crown. The former type showed affinity for certain surfaces. Although more comparative data are necessary for further conclusions, it seems safe to state that only moderate dental hypoplasia existed in this group. The existence of a racial factor is not regarded as proved.—*Author (courtesy Wistar Bibl. Serv.)*.

7235. **SURE, BARNETT, HARVEY S. THATCHER, and DOROTHY J. WALKER. Avitaminosis. I. Pathologic changes in nursing and in weaned albino rats suffering from vitamin B deficiency. II. Pathologic changes in the albino rats suffering from vitamin G deficiency.** *Arch. Path.* 11(3): 413-424; 425-433. 3 fig. 1931.—I. In 67 young nursing albino rats suffering from a deficiency of vitamin B complex, fatty metamorphosis of the liver was observed, also atrophy of the spleen, hemorrhages in osteogenic tissues, and anhydremia associated with disturbance in hematopoietic function. In 80 young nursing albino rats suffering from uncomplicated vitamin B deficiency there was marked reduction in the glycogen content of the liver, atrophy of the spleen, hypoglycemia and anhydremia associated with hematopoietic disturbance. In 15 weaned young rats deprived of vitamin B complex, the pathologic changes were mainly those of inanition, with cardiac and adrenal hypertrophy and fatty metamorphosis of the liver in some cases. In 2 groups of weaned albino rats suffering from uncomplicated vitamin B deficiency, splenic atrophy and adrenal and cardiac hypertrophy (the last due mainly to increased blood volume) were observed. In the 1st group, 14 rats receiving no vitamin B whatever, inanition and loss of weight occurred. In the 2nd group, 15 rats given inadequate amounts of vitamin B, some small gains in weight occurred, emphasizing the associated atrophic and hypertrophic changes. The authors find that vitamin B per se possesses the function of producing growth unrelated to food intake. Uncomplicated vitamin B deficiency produces lymphopenia and a corresponding polymorphonuclear leucocytosis.—II. Vitamin G deficiency was produced in 64 albino rats on a variety of diets. The main symptoms were cessation of growth, loss of weight, and dermatitis. Other symptoms in some animals were ophthalmia, chromogenic urine, and incontinence of urine. No correlation was found between loss of body weight and the onset of skin lesions, and it is therefore concluded that the antidermatitic and growth-promoting syndromes are not identical. A seasonal variation was noted in the occurrence of the dermatitis. Alopecia, ulceration of the skin, atrophy of the spleen and of the thymus, fatty changes of the liver and hemorrhages and congestion of the intestines were the main pathologic changes.

7236. **TROITZKAJA, A. D. Morphologische Blutveränderungen und die Bedeutung der Klassifikation der Neutrophilen nach Arneth bei Syphilis.** *Arch. Dermatol. u. Syph.* 159(3): 482-490. 1930.—The blood picture was studied in 30 cases of congenital syphilis. There was an oligocythemia with high color index. The red blood picture thus resembled chlorosis and also more or less strongly, chloranemia. The lymphocytes were increased in number; and the neutrophiles without exception showed a shift to the left.

7237. **TWORT, C. C. The aetiology of lymphadenoma: A summary of six years' researches.** *Jour. Path. and Bact.* 33(3): 539-564. 1 pl. 1930.—Histologic examinations of healthy and diseased organs, examination of diseased tissues by "special technique" for vegetable parasites, and by dark ground illumination, the various silver precipitation methods, intense staining with Giemsa, Twort, Pappenheim-Unna, Mann, etc., special treatment of sections and films with acids, alkalis, antiformin, glycerine, soft soap, etc., for animal parasites gave negative results. Rabbits, guinea-pigs and mice were inoculated with lymphatic glands, liver, spleen, kidney, bone-marrow, brain, blood, etc., in the fresh state or preserved in saline, broth, glycerine, etc.; all without success. Attempts to cultivate a specific parasite on artificial media, and tubercle bacilli in lymphadenomatous tissues, likewise failed, as did examinations of allergic reactions to tuberculin in patients' feces, of blood for lipase content, and of blood and urine for antigens and antibodies.

7238. **WARBURG, BETTINA. Experimental poliomyelitis. Histology of the persistent lesions of the central nervous system.** *Arch. Neurol. and Psychiatr.* 25(6): 1191-1232. 34 fig. 1931.—In the central nervous systems of 15 *Macacus rhesus* monkeys surviving the onset of acute poliomyelitis, pathologic changes were: (1) degenerative and inflammatory (perivascular and extra-adventitial infiltration, degeneration of the nerve cells and fiber tracts), and (2) reparative (proliferation of microglia, astrocytes, and capillaries); these changes were variously distributed through the spinal cord and ganglia, medulla and pons, midbrain, basal ganglia, cortex and cerebellum. Inflammatory areas persisted in the central nervous systems of 4 animals which had made a good functional recovery.

7239. **WATSON, A. F. Experimental tar tumours in the white rat.** *Jour. Path. and Bact.* 34(3): 301-306. 1931.—Skin tumors were obtained in 2 ♂♂ and 2 ♀♀, from a litter of 6 ♂♂ and 5 ♀♀, by periodical treatment of the skin with a petroleum ether extract of rat tissues, followed in each case by applications of a gas works coal tar. The tumors of the ♂♂ were squamous cell carcinomata and once initiated grew vigorously, 1 animal showing extensive metastases in the lungs, both kidneys, and the pleural cavity. The tumors of the ♀♀ grew less vigorously; only 1 case showed histological evidence of local infiltrative growth.—*A. F. Watson*

7240. **WEBER, HERBERT. Ein Papillom der Pul-**

monalklappe. *Centralbl. Allg. Path. u. Path. Anat.* 48 (2): 49-54. 3 fig. 1930.—In a man who had died from croupous pneumonia, the heart was enlarged, and the papilloma was attached to the valve by a stalk. There was marked infiltration of the subendothelial layer of the surrounding tissue.

ANIMAL PATHOLOGY

7241. **ACHARD, CH., et M. ENACHESCO. De l'action réciproque de la chloruration et de l'alcalinisation de l'organisme dans les maladies aiguës. 1. Épreuve de chloruration.** *Jour. Physiol. Path. Gén.* 28(3): 587-595. 2 fig. 1930.—NaCl was given orally in 10-15 gm. doses repeatedly, and the chloride content of serum and urine, together with the alkaline reserve of the blood, the urinary pH, and carbonate were determined in cases of pneumonia, acute rheumatism, catarrhal jaundice, angina, and convalescence after infective fevers. The fate of the administered chloride depends on the presence or absence of chloride retention due to the disease, but any increase in retained chloride is not necessarily associated with a decreased alkali retention.—*W. R. Fearon.*

7242. **ACHARD, CH., et M. ENACHESCO. De l'action réciproque de la chloruration et de l'alcalinisation de l'organisme dans les maladies aiguës. II. Épreuve d'alcalinisation. Épreuve mixte de chloruration et d'alcalinisation.** *Jour. Physiol. Path. Gén.* 28(3): 612-623. 4 fig. 1930.—In health, reciprocity exists between chlorides and alkalies, retention of the one being followed by expulsion of the other. This relationship does not obtain in acute diseases, when chloride retention and alkalosis may develop separately or together.—*W. R. Fearon.*

7243. **ADLER, ALFRED. Studie über Minderwertigkeit von Organen.** 2nd edit. 92p. G. F. Bergmann: München, 1927. 4.20 M.—Since the appearance of the 1st edition (1907), the correctness and fruitfulness of Adler's views as to disposition to disease—as being related to morphological (hereditary) or functional inferiority of organs—have been confirmed by numerous discoveries and developments. Endocrine disorders, underdevelopment of testes (as found by Kyrle) and other parts of the genital system, compensatory overdevelopment of "inferior" organs, psychical disturbances due to—or revealing—organ inferiorities, the development of cancer in inferior organs, are some of the lines of investigation to which this theory is related. This edition presents the original doctrine, in the light of the progress of the past 20 yrs. (See also B. A. 6(2): Entry 3275.)

7244. **AKIYA, MINORU. Klinische und experimentelle Studien über die anorganischen Salze und das Säurebasengleichgewicht im Blut beim Fieber.** *Zeitschr. Klin. Med.* 109(3/4): 312-341. 1928.—Determinations of hemoglobin, serum protein, Ca, chloride, K, Na, Mg, inorganic P and pH are reported.—*R. S. Anderson.*

7245. **ALIPOV, G. Experimentelle Beiträge zur Frage der Pathogenese des traumatischen Schocks. (Zur Theorie der traumatischen Toxämie von Quénu.)** *Deutsche Zeitschr. Chir.* 228(6): 349-364. 1930.—Experiments were made on 20 dogs and 10 cats, and included 11 experiments on dogs and 9 on cats with mechanical lesions by the method of Cannon and Bayliss, and 10 experiments in stimulation of the nerve trunk. The conclusions are: "The occurrence of injurious, aseptic, protein disintegration products in the injured tissue has not yet been proved. The development of traumatic shock under the influence of absorbed, aseptic, degenerative products of body tissue, injurious to the organism, has not been confirmed in these experiments on animals. Therefore Quénu's theory of "traumatic toxemia" as the chief cause of shock is not accepted. Changes which occur in the body in conditions of shock can best be explained from the standpoint of the nervous mehanism and in the light of Crile's theory. The satisfactory results of early operation as recommended by Quénu in severe injuries and in shock can be explained otherwise than by the prevention of a traumatic toxemia."—*H. M. Zimmerman.*

7246. **ARKUSSKY, I. Über Jodausscheidung durch den Organismus unter dem Einfluss der Röntgenbestrahlung.** *Strahlentherapie* 31(4): 806-811. 5 fig. 1929.—The author reports on the change of I excretion in the urine under the influence of Roentgen radiation in 70 patients with malignant tumors. He is inclined to ascribe the major influence on the amount of I excretion to the radiated tumor tissues. He assumes that the I output from the tissues depends on the degree of tissue decomposition. He found in lymphogranuloma, ovaphoroma, seminoma, lymphosarcoma and others larger I excretion after radiation than in carcinoma. Accordingly the I excretion after treatment and its rise after exposure to x-rays is a measure of the radio sensibility of the tumor, of the degree of regressive processes and of the prognostic expectations.—*I. Arkussky (transl. by E. A. Wolf).*

7247. **AYKROYD, W. R. Beriberi and other food-deficiency diseases in Newfoundland and Labrador.** *Jour. Hyg.* 30(3): 357-386. 1930.—Beriberi occurring on a white-flour staple is similar to that occurring on a rice staple. Under the climatic conditions of North Newfoundland and Labrador, families are obliged to buy food stores in November or December to last until the following May or June. When poverty prevents a sufficient variety of foodstuffs, and calories are the foremost consideration, white flour with few extras forms the main dietary, and beriberi tends to occur in April, May or June. It occurs in families who have grown few vegetables and shot little game. The disease attacks more men than women, and very rarely children between the ages of infancy and puberty. The age and sex incidences of beriberi are difficult of explanation and differ in different countries. Infantile beriberi probably occurs in Newfoundland and Labrador, but is largely unrecognized. The main cause of beriberi is vitamin B_1 deficiency, but the diets of patients suffering from beriberi are deficient in other respects. It is suggested that the infrequency of wet beriberi in Newfoundland may be due to the fact that wheat flour has a higher protein content than polished rice. Since poverty and deficiency disease are rigidly associated, prevention is an economic rather than a medical problem. Severe scurvy and rickets are not often met. Functional hemeralopia or night-blindness occurs mainly during the summer among men. It occurs on a diet deficient in vitamin A, and is rapidly curable by vitamin A containing foods, a fact well known to the Newfoundlanders. The disease may occur in men taking a deficient diet for less than one month. Other evidences of vitamin A deficiency are lacking. Tuberculosis, severe dental caries, functional stomach complaints and constipation are common. Gastric and duodenal ulcer, diabetes and obesity are rare.—*Author's summary.*

II. Mitteilung. Zum Kohlenhydratstoffwechsel. *Zeitschr. Kinderheilk.* 45(3): 289-295. 1 fig. 1928.—The retarded glycolysis found by Freudenberg and Welcker in the blood of rachitic children, also demonstrated by Brock and Welcker in the blood and liver pulp of rachitic rats, is to be considered as an interference with the fermentative synthesis of sugar with phosphate to hexose-phosphoric acid preceding glycolysis, since the hexose-phosphoric acid ester itself can be further split to trioses. The lessened synthesis, previously found by us in the muscles of rachitic rats, together with this retarded glycolysis, shows that the fermentative, assimilative reactions in carbohydrate metabolism, proceeding endothermically in florid rickets as signs of the slowing of metabolism, are depressed. The glycogen content of the muscles of healthy and rachitic rats shows extraordinary individual variations. The glycogen content seems to be without significance as far as the ability of the muscles to synthesize hexose with phosphate to hexose-phosphoric acid ester is concerned.—*Authors' summary (transl. by J. B. Youmans).*

7249. **BABES, A. Les lésions du thymus chez le lapin consécutives à l'intoxication par le goudron.** *Bull. Assoc. Française Étude Cancer* 18(8): 675-687. 4 fig. 1929.—The thymus in rabbits injected with tar is characterized by considerable atrophy of the lobules of the thymus and by an abundance of connective tissue. The thymic lobules now form only a small portion of the microscopic field or, rather, a large portion of these are formed exclusively of connective tissue. The lesions correspond to that of accidental involution of the thymus, to a more pronounced degree than those (lesions) which we have described as the modifications of the third degree. There is no doubt that the greatest importance of this phenomenon lies in the diminution even to the point of disappearance of the lymphocytes.—*A. Babes (transl. by A. H. Gardiner).*

7250. **BABES, A. Les modifications de l'hypophyse consécutives aux badigeonnages et aux injections de goudron.** *Bull. Assoc. Française Étude Cancer* 18(8): 723-726. 1929.—The animals that died as a result of injections or applications of tar showed a very marked diminution of the eosinophiles, a diminution which in the case of the rabbits that died between the 17th and 34th day, with the exception of one case, reached the complete disappearance of these elements.—*A. Babes (transl. by A. H. Gardiner).*

7251. **BALYEAT, RAY M., and F. L. BRITTAIN. Allergic migraine, based on the study of fifty-five cases.** *Amer. Jour. Med. Sci.* 180(2): 212-222. 1930.—The hereditary factors in migraine are apparently identical with those of asthma and hay-fever, suggesting a common etiology.—*W. H. Manwaring.*

7252. **BEHREND, MOSES. Efficiency of the various types of anastomoses of the hollow viscera. Clinical and experimental data.** *Ann. Surg.* 91(4): 514-519. 1930.—All types of gastrointestinal anastomosis were performed on dogs. The x-ray and the general nutrition of the animal were used to determine the efficiency of the operation. In almost all instances the dog died after a Billroth No. 2 or a resection of the stomach, and the reason was not evident. If the dog survived the operation, the type of operation was not important, and the anastomoses were all efficient. An x-ray of the normal stomach of the dog can well be compared to those taken in man. Only the physical results of anastomoses in animals can be compared to those in man, for in the latter there is present some disease of the viscera. In man the kind of anastomosis is immaterial, if the stoma is proper in size and position.—*B. C. Russum.*

7253. **BÉNARD, HENRI, JACQUES LENORMAND, et FÉLIX-PIERRE MARKLEN. Étude comparative des variations du chlore et du sodium sanguins dans l'acidose rénale.** *Bull. et Mém. Soc. Méd. Hôp. Paris* 45(23): 894-902. 2 fig. 1929.—Both blood chloride and Na show considerable variation in renal acidoses. Certain types of nephritis are associated with low alkaline reserve and low blood chloride. There seems no relation between Cl ion and Na ion, and their relation alone does not afford an explanation of the mechanism of acidosis in nephritis. Often hyperchloremia is associated with low Na content and vice versa. In renal acidosis, then, with or without edema, the two minerals may show independent values. Other factors must enter into disturbance of the acid-base equilibrium, probably organic substances and proteins.—*B. Bickel.*

7254. **BERGAMI, GINO. Variazioni del potere uricolitico del fegato di cani operati di stenosi della vena cava. [Variations of uricolytic activity of liver in dogs with stenosis of the vena cava.]** *Boll. Soc. Ital. Biol. Sperim.* 5(4): 522-524. 1930.—Following operative stenosis of the vena cava in dogs the uricolytic activity of the liver is subnormal.—*M. Comel.*

7255. **BERLINER, M. Untersuchungen über optisch wahrnehmbare Phänomene an Punktionsflüssigkeiten bei Carcinom- und anderen Krankheiten. Zugleich ein Beitrag zur Kenntnis der Gerinnungsvorgänge.** *Zeitschr. Krebsforsch.* 32(1/2): 171-181. 4 fig. 1930.—In 20 puncture fluids, 12 of which were from cancerous patients, the effect of admixture of these with sera from various sources was studied by means of the nephelometer. In all those of cancerous origin there was a development of definite turbidity in such mixtures regardless of the source of the serum. A lesser reaction was shown by tuberculous exudates, still less by those of pneumonia and by transudates and cystic fluids. The author suggests the value of study of the earlier stages of colloidal aggregation by means of the nephelometer.—*H. E. Eggers.*

7256. **BICKEL, A. Dysoxydative Carbonurie und Krebskrankheit.** *Zeitschr. Krebsforsch.* 32(1/2): 110-111. 1930.—By the term "dysoxidative carbonuria" Bickel designated a relative increase in the urinary output of C over N—a finding which is frequent in cancerous disease. This he ascribes to the anoxidative destruction of glucose in the cancer cell, as well as the general sharing in this process of even the non-cancerous tissues. As the phenomenon is not constant, B. urges that the conditions in which it occurs should be more closely investigated.—*H. E. Eggers.*

7257. **BODNÁR, J., und JOHANN STRAUB. Biochemische Untersuchung des endemischen Kropfes in Ungarn, auf Grund der Jodmangeltheorie.** *Biochem. Zeitschr.* 227(1/3): 237-244. 1930.—The iodine modification obtained in connection with the great goitre endemic (82% of school children and 24.6% of the general population were found goitrous), in Bodahegykozseg, Hungary, leads to the following conclusions: (1) The I content of the drinking water is 0 to 1γ per liter. (2) The I introduced through the food supply of each child amounts to 15.8γ daily. The daily urine of goitrous children contains an average of 8γ of I, while that of healthy children and adolescents contains 31 to 25γ. All of these results, as well as the fact that the goitre of children regresses markedly with I, prove, at least in the cases presented, the undoubted correctness of the I deficiency theory of goitre.—*Authors' summary (transl. by E. H. Boyer).*

7258. **BONOMO, VINCENZO. Sulla patogenesi dello shock traumatico. [The pathogenesis of traumatic shock.]** *Arch. Ital. Chir.* 24(2): 145-174. 1929.—A hemostatic ligature was applied to 3 dogs (part of the body not stated) without anesthesia, for about 7 hrs., with production of intense pain. Immediate fall of arterial pressure with all the signs of grave shock followed removal of the ligature, with death in 10 minutes in one case and after 6-10 hrs. in the others. In 2 dogs the left femoral artery and vein of 1 hind leg, and in another the femoral vessels of both hind legs, were compressed without anesthesia for about 3 hrs. None showed sign of shock or change in arterial pressure, though one interrupted the experiment by repeated vomiting and died in 12 hrs.; the others survived. In another dog, after compression for 5 hrs. of the left iliac artery and "primitive" iliac, the limb was cold and the tissues became livid. Removal of the compres-

sion was followed by very slight fall in arterial pressure; the femoral pulse began to beat and the color of the tissues improved. There was no sign of shock after 3 hrs. The author's conclusion is that some other factor than interruption of circulation (or the entrance into the blood of toxic substances from the forcibly checked region of circulation) enters into the production of shock, and that this factor is pain or intense stimulation of the nerve centers.

7259. **BRDICZKA, GEORG. Beiträge zur Kenntnis der biologischen Einwirkung der Röntgenstrahlen bei Tuberkulose. I. Biologische Leukocytenkurven bei röntgenbestrahlten Fällen von Lungentuberkulose.** *Beitr. Klin. Tuberk.* 72(3): 298-311. 11 fig. 1929.—Blood pictures of patients with a productive cirrhotic type of tuberculosis were studied during and after radiation. Heavy filtered rays (½ mm. Zn) were used at 30 cm. focal distance and applied in doses of 1/40 to 1/10 of a skin unit dose. These doses were given weekly up to a total of 20 to 70% of the skin unit dose. For comparative blood examinations, 200 cells were counted 2-3 times a week. The sedimentation rate was studied at the same time. Of the 31 patients, 4 responded with an eosinophil reaction, 4 with a predominantly monocytic, 12 with a polymorphic and 2 with a reduction reaction (temporary disappearance of eosinophils and drop in lymphocytes), while 4 showed no reaction.—*O. Glasser.*

7260. **BRICKER, F., und F. SUPONIZKA. Zur Lehre von der Entzündung. III. Der Kohlenhydratstoffswechsel des entzündeten Gewebes im Initialstadium der Entzündung.** *Arch. Exp. Path. u. Pharm.* 129: (1/2): 100-107. 1928.—Examination of venous blood from normal rabbits' ears revealed little variation in carbohydrate metabolism. In inflamed ears there was a greater amount of sugar than normal. Conclusions were that: 1. Sugar is not abstracted from arterial blood of inflamed tissue; 2. More sugar is formed in inflamed tissue. Results are the same in tissue fluids as in blood. The amylolytic index indicates that there is an increase of carbohydrate splitting in inflamed tissue. Degree of reduction of respiratory coefficient indicates decreased combustion and less sugar resorption in inflamed tissue. Methods and tables are included. Short bibliography.—*A. E. Taft.*

7261. **BRICKER, F., und J. LASARIS. Zur Lehre von der Entzündung. IV. Der Stickstoffwechsel im Anfangsstadium der Entzündung.** *Arch. Exp. Path. u. Pharm.* 129(1/2): 122-132. 1928.—Metabolism in inflammatory tissue is characterized by the fact that more protein is split, but that less completely than in the normal. Determinations showed that the first split products of protein in blood from inflamed rabbits' ears were the important factors. When poured into the blood stream, these give rise to secondary phenomena in the organism, with production of proteases and peptones. These produce the same effect as protein therapy. The greater the coefficient of qualitative oxidation of protein, so much less is protein split, and conversely. In fractional examination of tissue cultures, the substance which most increases growth is represented by the first split products of protein. The peptose forms are the most active. Methods and tabulated results, with a brief bibliography, are included.—*A. E. Taft.*

7262. **BRICKER, F. Zur Lehre von der Entzündung. V. Azetonkörper im Blute des entzündeten Gewebes.** *Arch. Exp. Path. u. Pharm.* 129(5/6): 285-287. 1928.—In the blood which streams from the inflamed ear, the acetone content is greater than in the blood from the non-inflamed ear. This increased acetone formation is sometimes weakly and again strongly expressed. Evidently, in the processes of increased metabolism, split products are formed, due to an incomplete oxidation of organic materials.—*J. S. Latta.*

7263. **BUCHMAN, JOSEPH, and ISAAC F. GITTLEMAN. Inorganic blood chemistry in the osteochondritides.** *Amer. Jour. Dis. Children* 40(6): 1250-1261. 8 fig. 1930.—A series of 43 cases, including vertebral epiphysitis, osteochondritis of the vertebral body, Legg-Perthes' disease, Osgood-Schlatter's disease, Koehler's disease of the tarsal scaphoid and cases of displaced upper femoral epiphyses, furnished no evidence of rickets; the inorganic P, Ca, Na, K and Mg content of the serum was well within normal limits.

7264. **CAPUANI, GIAN FRANCO. La colloido-labilità plasmatica nella tubercolosi. [Lability of the plasma colloids in tuberculosis.]** *Policlinico [Sez. Med.]* 37(7): 329-337. 1930.—From about 1200 plasma reactions (about 1000 with the Fahraeus reaction, 200 with the Costa method, of which 100 were parallel with the Fahraeus) and 40 serum reactions (Matefy and Daranyi methods), Capuani concludes that plasma lability is caused by disturbance, due to the toxemia of necrobiosis, of the normal equilibrium among the various protein constituents of the plasma, and that it is not specific for any disease.—*From author's summary (transl.).*

7265. **CAUER, H. Neue Untersuchungsergebnisse über das Jodvorkommen und sein Zusammenhang mit dem Kropf.** *Zeitschr. Ges. Physikal. Therap.* 39(1): 10-50. 5 maps. 1930.—In the provinces of Upper Hesse, Rhenish Hesse and Starkenburg, there appeared to be no direct relation between the I content of the soil and the occurrence of goiter, but a very clear relation between goiter and lack of I in the water (and also bad social conditions). The factor which Cauer emphasizes, however, is the I content of the air. In agreement with von Fellenberg, he finds that rain, fog and snow wash I out of the air, but that the air is again enriched by evaporation from the soil. Hence it would be expected that the air of predominantly cloudy and foggy regions would be poor in I. That part of the I in inspired air is resorbed by the lungs Cauer shows by a table of I values of air in a dark room (av. 0.545γ per cu. meter, and in exhaled air, 0.43γ per cu. meter) showing a retention of the lungs of 0.115γ I per cu. meter inhaled air, or about ¼ the I content of the air. At Bad Kreuznach in fine weather the average daily I content of the atmosphere is about 2γ per cu. meter; if resorption were only ¼, a man would get a daily dose of 25-30γ I per day. That inhalation of I has a favorable influence on goiter is indicated by a clinical experiment on a goiter patient, in whom 14 days' inhalation treatment produced a marked reduction in the size of the goiter, which again increased in size on cessation of treatment. Cauer found a much higher percentage of I in chlorophyl-rich than in chlorophyl-poor leaves, and a larger proportion of the I in organic combination in the chlorophyl-rich leaves. Hence he deduces that I is not a foreign substance in plants, but has a function to perform. In the green leaves of *Campanula rotundifolia* from Kühtai, Tyrol, 2000 meters above sea level, he found an average of 5041γ per kgm., while green leaves of the same plant from Kuhberg near Kreuznach, only 250 meters above sea level, where the air is rich in I, gave an average of 3300γ per kgm. This might at first glance seem to indicate that the I content of the air is without influence on vegetation, and that vegetable I is drawn from the soil. Cauer calculates, however, that the I content of a blackberry bush, for instance, could not possibly be drawn up by the roots or derived from the earth. He suggests that the decay of organic material in the earth may set free gaseous I, which is resorbed by the leaves; and that intensive solar irradiation may enable plants which grow at high altitudes to resorb more I than the plants which grow in the I-rich atmosphere of lower levels. Fog maps and goiter maps of the 3 provinces studied show a certain degree of correspondence.

7266. **CHINI, VIRGILIO. Ricerche sperimentali sull' azione locale dell'acido urico sui tessuti. [Local action of uric acid on tissues.]** *Boll. Soc. Ital. Biol. Sperim.* 5 (4): 519-522. 1930.—Injection of uric acid solutions is followed in rats by local response in subcutaneous and muscular tissues, an inflammatory process leading to a granuloma being developed; the latter is gradually enclosed by a reactive connective tissue capsule. When uric acid suspensions are injected, the uric acid is chiefly retained locally, and exerts on the surrounding

tissues an irritant action. Granulations grow to involve the injected matter, and gradually an incapsulation by connective tissue follows. Some morphological data observed (such as presence of giant cells, and aspect of the stroma in the zone of uric acid deposition) recall morphological findings recorded in arthritis and gout.—*M. Comel.*

7267. **CIAMBELLOTTI, E. Erpete recidivante del volto di probabile natura anafilattica. [Recurrent herpes facialis of probable anaphylactic nature.]** *Dermosifilografo* 3: 523-543. 1928.—In 1 case of recurrent herpes facialis the hypersensitivity to ovarian products is shown. By means of intradermal injections of such products, premonitory phenomena of herpetic efflorescence were elicited. These were reduced and finally made to disappear by recurrent menses. In order to explain the appearance of a center of hypersensitivity so limited and constant, something in the nature of anaphylaxis is suggested aside from the herpetic virus inducing herpetiform efflorescence. Data on a theory of anaphylactoid syndromes are set forth.—*E. Ciambellotti (transl. by J. G. Edwards).*

7268. **CIAMBELLOTTI, E. Valore e costanti di errore nella ricerca del quoziente respiratorio e del metabolismo basale nei dermopatici. [Value and constants of error in the study of the R.Q. and B.M. in dermopathics.]** *Arch. Ital. Dermatol. Sifilogr. e Venereol.* 4(2): 101-165. 1928. Determinations of R.Q. and B.M. in dermatological patients can be of great service, but a systematic and prolonged study is necessary in the same subject and in the different phases preceding and following the disease. Such measurements indicate the condition of the system at the time they are made and the development of the dermatosis as well as the disturbing action that the cutaneous form exercises on the interrelation, directly and through reactions arising within the organism. The determination is frequently vitiated because of unavoidable error depending on the same dermatosis: pruritus, excitement, insomnia, abnormal reactions of the central and sympathetic nervous systems through functional and anatomical changes of the skin, large anatomico-pathological lesions, exudates, vicarious hyperfunction, absorption from necrotic and suppurative processes,—all these are active causes introducing error in the study. Account is taken of all these causes. The experimental data cannot be precise in their absolute value but interpretative. Examples are given and interpretations set forth.—*E. Ciambellotti (transl. by J. G. Edwards).*

7269. **CIMINATA, A. Guarigione del diabete pancreatico sperimentale, con la enervazione operatorio delle glandule surrenali. [Cure of pancreatic diabetes by denervation of the suprarenal gland.]** *Boll. Soc. Ital. Biol. Sperim.* 3(9): 1251-1260. 1928.—Extirpation of the pancreas produced diabetes in the dog. After denervation of the suprarenal the diabetic symptoms disappeared. Within a few days the diabetes was cured although mixed diet with high carbohydrate was given. The immediate response of the glycogen curve within 3 days proved the effect of suprarenal nerves upon diabetes. The number of Islands of Langerhans in the pancreatic tissue was found small. Four laparotomies were required for this experiment. The animal tolerated the intervention well, and began to gain weight and spirit immediately after the section of the suprarenal nerves.—*B. Bickel.*

7270. **COLLAZO, J. A., B. VARELA, y P. RUBINO. Hipervitaminosis D y tumores. Adenomas difusos con degeneración maligna inicial del estômago del conejo, producidos por la ergosterina irradiada en exceso. [Hypervitaminosis D and tumors. Diffuse adenoma with beginning malignant degeneration of the rabbit stomach, produced by excessive irradiated ergosterol.]** *Arch. Argentinos Enfermedades Aparato Digest. y Nutricion* 4(1): (1-16). 5 pl., 6 fig. 1928.—Rabbits fed corn meal, green alfalfa, water, and irradiated ergosterol in doses 5,000 times the therapeutic dose, receiving a total of 250 mgm., developed initial symptoms of epithelioma with invasion of the submucosa, and died in 30 days. Thus experimental tumors were produced by biologic agents which are constantly present in the food of man and animals.—*B. Bickel.*

7271. **DRAKE, T. G. H., P. MARSH, and J. L. GAMBLE. The alkalosis of vomiting and the acidosis of advanced renal disease.** *Amer. Jour. Dis. Children* 40(4): 705-717. 1930.—The data presented show the changes in the ionic composition of the blood plasma produced by continued vomiting [7 cases] and those found in the presence of advanced renal disease [in 2 cases]. The extent of repair obtained by the subcutaneous and intravenous injection of water and the substances indicated is also recorded by means of direct measurements of the chief factors of plasma structure.—*Authors' summary.*

7272. **DULIÈRE, W. Action sur l'intestin isolé de Mammifères de nouveaux amino-ethers du groupe des éphédrines. [Action on the isolated intestine of mammals of new amino esters of the ephedrine group.]** *Compt. Rend. Soc. Biol.* 97(26): 905-906. 1927.—Amino esters of the ephedrine group usually inhibited the isolated intestine (rabbit and cat) in concentrations of 1 in 500,000 and upwards but liminal doses sometimes produced stimulation. Natural ephedrine on the other hand always augmented the intestinal movements.—*A. J. Clark.*

7273. **EASTWOOD, ARTHUR. Systemic influences in immunity and cancer.** *Jour. Hyg.* 30(3): 267-299. 1930.—The idea that there are systemic influences concerned with the genesis of cancer has assumed many forms and is often expressed ambiguously. Does it mean that normal cells have a "natural tendency" to malignancy and will actually become malignant if freed from systemic control? Eastwood does not accept this; unrestrained growth does not suffice to explain the origin of cancer. By "systemic control" the author means control which regulates normal cells and he believes cancer cells to be independent of it; nor does he agree that there is a special kind of antimalignant systemic control which may destroy the fully fledged cancer cell. By "susceptibility" Eastwood means an essentially cellular property, not a humoral or systemic influence, though he admits that irritant material which gains access to the circulation may increase the susceptibility of particular cells. Eastwood also discusses the meaning of "resistance" (either local or systemic) to cancer. Owing to the recuperative powers of the animal body, local disturbances of metabolism are often corrected and there is a return to the normal condition; some of these disturbances, if left uncorrected, might have led to cancer and the fact that they have been corrected may, the author feels, be called resistance to the genesis of cancer. It is also known that true cancerous foci or metastases may remain quiescent for a considerable time. But Eastwood does not believe that such quiescence has been shown to be attributable to a specific kind of antimalignant "resistance" (either local or systemic). While there is no satisfactory evidence, either direct or indirect, of a systemic influence which causes cancer, systemic influences are so complex and obscure that this possibility cannot be definitely excluded. But the author does not feel there is any cogent reason for dissenting from the view that the production of the malignant variant is due to its local environment.

7274. **EICHHOFF. Experimentelle Appendicitis.** *Arch. Klin. Chir.* 162(Kongressbericht): 178-181. 1930.—Attempts to produce appendicitis in 18 rabbits without stenosis or with incomplete stenosis were unsuccessful, even with trauma to the mucosa and injection of enterococci, colon bacilli, pneumococci, streptococci or Fränkel's bacilli. Complete stenosis without bacterial infection produced appendicitis in 2 out of 6 rabbits. Complete stenosis produced gangrenous appendicitis in 3 out of 4 rabbits injected with streptococci, and in 15 out of 19 injected with Fränkel's bacilli. Trauma made no difference in the production or non-appearance of appendicitis.

7275. **ELSNER, ERICH. Die unspezifische Bereitschaft der Haut zur Blasenbildung bei Hautkrankheiten.** *Arch.*

Dermatol. u. Syph. 161(3): 574-585. 1930.—The following conclusions are drawn from experiments on 100 dermatologic patients and 23 healthy subjects. According to Hahn, intracutaneous injections of aqueous urea solutions may produce bullae within a few minutes without notable discomfort or damage. By this method the "blister threshold" of the skin may be determined quantitatively within a short time. The threshold or effective point is a constant in any given individual and region on his body. Flexor surfaces show a response to concentrations varying from 10-12%, exceptionally exhibiting vesiculation with concentrations as dilute as 9%. One hundred patients suffering from various dermatoses were given tests in areas of non-involved skin, and 95 of these showed normal threshold values. The presence of dermatoses has no influence on the responsiveness of the skin to non-specific vesicle-producing urea solutions. Of the 5 patients exhibiting atypical response, 2 developed blisters on the forearm after injection of an 8% solution, and 3 required a concentration of 13%. These exceptions cannot be attributed to the associated dermatoses, as other patients showing the same dermatoses evidenced no alteration in blister-threshold values. Lowered threshold values were seen in involved areas of patients with epidermolysis bullosa and naevus anaemicus. Elevated values occurred in zones showing dermatographic or urticarial wheals. It seems probable that the increased permeability seen in these disorders lasts for a variable length of time, as suggested by the varying concentrations required to produce vesiculation.—*Author's summary* (*transl. by J. A. Gammel*).

7278. **FAULEY, GORDON B., and A. C. IVY. Experimental gastric ulcer: the effect of the consistency of the diet on healing.** *Arch. Internal Med.* 46(3): 524-532. 6 fig. 1930.—In 9 rabbits a simple ulcer produced by excision healed within 30 days irrespective of the consistency of the diet (5 rabbits on soft diet, 4 on rough). Of 22 rabbits with anterior lesion plus silk suture, all fed on soft diet, 5 died prematurely; of 17, killed on the 30th day, only 3 showed unhealed ulcers. Of 12 rabbits with anterior lesion plus silk suture, fed on rough diet, all that were killed on the 30th day had typical chronic ulcers; 1 killed at 42 days showed complete healing, but others kept for longer periods than 30 days failed to show complete healing. These results indicate that the consistency of the diet has an influence on the healing of an ulcer.

7279. **FERRARI, RODOLFO. Influenza delle proteine del sangue sulla scomparsa dell'edema nella rana salata. [Influence of blood proteins on the disappearance of edema in the perfused frog.]** *Boll. Soc. Ital. Biol. Sperim.* 5(6): 838-840. 1930. The diminution of edema in perfused frogs is related to an increase in blood protein, the edema showing the greatest intensity when blood protein is lowest, diminishing when the latter increases, and disappearing when the blood protein reaches normal values.—*M. Comel.*

7280. **FISCHER. Züchtung von Karzinomgewebe in vitro.** *Arch. Exp. Zellforsch. bes. Gewebezücht.* (*Explantation*). 6: 138-141. 1928.—Mammalian carcinoma cells may be grown indefinitely in vitro, retaining malignancy. Mouse carcinoma cells infiltrate and destroy normal tissue, living or dead, homologous or heterologous. They grow unhindered in an animal medium into which the carcinoma can not be transplanted. Carcinoma cells outgrow all normal cells, even fibroblasts; in sharp contrast to all normal epithelium. They can utilize intercellular growth principles, besides those specific for their own cell type.—*Author's summary* (*transl. by M. C. Marsh*).

7281. **FISCHER, A., H. LASER, und H. MEYER. Ein 3 Jahre alter Carcinomstamm in vitro. Einige Betrachtungen nach den bisherigen Arbeitsergebnissen.** *Zeitschr. Krebsforsch.* 32(1/2): 99-106. 3 fig. 1930.—During 3 years' continuous cultivation in vitro of mouse cancer tissue (Ehrlich's mouse carcinoma) a study was made of the relative growth of the tissue in heterologous and homologous media; its powers of infiltration in homologous and heterologous tissues; humoral and cellular growth factors; the reactions between normal and malignant tissue cells; the growth of cancer cells in plasma and serum-constituents; the effect on their growth of varying concentration of embryonal extract in the culture medium; the effect of varying H-ion concentration; the effects of varying O tension, of x-rays and radium emanations; the production of lactic acid; respiration experiments and chromosome counts. All these studies have been reported in detail; they show principally that the active proliferation of cancerous tissue in an individual cannot be regarded as the result of a general enhancement of growth rate, and that as yet no essential qualitative differences have been found between cancerous and normal tissues. Such differences as do exist are quantitative in character. If this conclusion is confirmed by the application of more delicate methods than those now available, it will follow that no sharp line can be drawn between normal and malignant tissues. The alleged importance to malignant growth of the association of stroma is not confirmed in the writers' experiments, since no normal tissues have been added to the cancer cultures for the last 1½ years, and the growth is that of a pure strain of epithelial cells. The cultivated cancerous tissue was extraordinarily sensitive to alteration of environmental conditions, and even with normal conditions it showed an early tendency to central necrosis not observed with normal tissues. A comparison of cancerous growth with the processes of normal growth and regeneration led to the somewhat paradoxical conclusion that the cause of the unlimited proliferation of cancer cells was to be sought in their short life duration and lessened resistance. As a matter of fact, in vitro cancer cells frequently grow more slowly than normal tissues, despite the relatively much more frequent appearance of mitoses among them. Their characteristic trait would appear to be an extreme lability, enabling them to respond by proliferation to irritants insufficient to affect normal cells, along with a tendency to chronic disintegration which itself serves as a stimulant to regeneration.—*H. E. Eggers.*

7282. **FISCHER, ALFRED E., and MIRIAM REINER. Pentosuria in children: with laboratory data on four cases.** *Amer. Jour. Dis. Children* 40(6): 1193-1207. 1930.—The unusual opportunity to observe 4 juvenile cases within a short time led the authors to study the relationship between pentose ingestion, pentosemia and pentosuria. The method of Somogyi for the separation of dextrose from nondextrose reducing substances in the blood by the addition of yeast lends itself very well to the study of pentosuria following the ingestion of pentose. It appears that the nonfermentable reducing substances of the blood are not increased in pentosuric persons. Their tolerance for dextrose is unchanged. When pentose is given to normal persons, the rise in pentose is slower than that in dextrose and reaches its maximum later, but is maintained longer than the rise in dextrose. The blood pentose curve in pentosuric persons is similar to that in normal persons. Only a small amount of the ingested pentose is accounted for in the urine and the stool. Fischer and Reiner were unable to determine the fate of the remainder. The output of ingested pentose by a pentosuric person lasts somewhat longer and is slightly greater than that by normal persons. Pentosuria is a metabolic disease and

is not due to an increased permeability of the kidney for pentoses.

7283. **GAETANI, G. F. DE. Ricerche sulla influenza dell'alimentazione sui tumori sperimentali da catrame. [Studies on the influence of nutrition upon the experimental tar tumors.]** *Boll. Soc. Ital. Biol. Sperim.* 5(3): 439-441. 1930.—Mice fed with spleen, meat and liver showed (especially when fed with crude spleen) an early development of the tar tumor growth. The mice fed with spleen show greater resistance to application of tar, whereas those fed with liver died from cachexia. The further development of the tumor depends upon the state of nutrition, being greater when the animal is in good condition, whereas the tumor regresses in weakened subjects.—*M. Comel.*

7284. **GATEWOOD, WESLEY E., OLIVER H. GAEBLER, EDWARD MUNTWYLER, and VICTOR C. MYERS. Alkalosis in patients with peptic ulcer.** *Arch. Internal Med.* 42(1): 79-105. 1928.—The authors studied the acid-base balance on a series of 46 patients with peptic ulcer undergoing the Sippy alkali treatment. A definite correlation was observed between the alkalemia and a group of clinical symptoms which were chiefly nervous in character. About ⅔ of these patients at some time showed a high CO_2 content or pH or both, and 21 showed an uncompensated alkalosis, i.e., electrometric pH values of 7.48 or above. These 21 cases all showed an increased bicarbonate concentration. In a number of cases pyloric obstruction was found to be the important factor in the production of the alkalosis. In such cases surgical relief of the pyloric obstruction restored the acid-base balance. When alkalies are used in the amounts called for in the Sippy treatment of peptic ulcer they almost always produce characteristic changes in the blood chemistry, even though symptoms of alkalosis may not occur. When $CaCO_3$ and MgO were employed without $NaHCO_3$, there was little evidence of alkalosis, if the complication of obstruction or vomiting was not present. The alkalosis was most marked at the end of the day and tended to return to normal during the night. With the rise in the blood bicarbonate there was a corresponding fall in the plasma chloride. The rise in the bicarbonate appeared to be accompanied in many cases by a slight rise in serum Na.—*V. C. Myers.*

7285. **GECK, OTTO F. Pellagra and tuberculosis—some remarks about the pathogenetic factors.** *Virginia Med. Month.* 57(4): 256-262. 1930.—From a review of the literature and a study of a large number of cases the author concludes that at the present status of our knowledge of pellagra, the dietary factor in the pathogenesis is not fully established, nor is the infectious hypothesis entirely rejected. In both directions further experiments are suggested. Chewing tobacco could be tested for eventual pellagra-preventive properties. Collection of data is needed to answer the questions how far are pellagrins "immune" against pulmonary or other tuberculosis, and whether pellagra itself is not possibly a special (nervous) form of tuberculosis.—*From author's summary.*

Edizioni Sapientia: Rome, 1930.—A polemic treatise, explaining and defending Gregoraci's theory that tumors are due to symbiosis between the body cells and certain "saprophytic" organisms living in these cells.

7288. **GRANT, AGNES H. The effect of rachitic diets on experimental tuberculosis. IV. Effects of disturbing optimal ratio between calcium, vitamin C and vitamin D.** *Amer. Rev. Tuberc.* 21(1): 115-125. 1 fig. 1930.—Resistance to tuberculosis can be decreased from a natural immunity to moderate susceptibility, without destroying the growth impulse, by a prolonged disturbance in the optimal balance between Ca, vitamin C and vitamin D of the diet. A prolonged excess of vitamin D in the diet, either with a deficiency of Ca or with a normal amount, hastens the spread of tuberculosis through the lungs. The substitution of vitamin C for vitamin D at the time of inoculation or the addition of vitamin C to a diet deficient in vitamin D tends to increase the amount of tuberculosis in the lung, rather than decrease it. The addition of vitamin C to a diet containing vitamin D tends to increase resistance to tuberculosis. The degree to which diets corrected after inoculation can retard the spread of tuberculosis in white rats depends upon the type of deficiencies and excesses in the diet before inoculation, and upon how long the deficient diets have been given.—*M. Lederer.*

7290. **GRAY, H., and JEAN M. STEWART. Quantitative diets versus guesswork in the treatment of obesity and diabetes.** *Sci. Monthly* 32(1): 46-53. 1 fig. 1931.—Gives figures to contrast 3 types of diabetic diets: high fat, i.e. FA/G 1.5, average, i.e. FA/G 1.0 approx., and high carbohydrate, i.e. FA/G about 0.5. All these are iso-caloric and iso-protein. If in the same clinic, in order to rule out the personal equation, patients should be fed now one of these types, now another, evidence as to relative merit might be obtained.—*H. Gray.*

7291. **GREENBERG, D. M., and LEWIS GUNTHER. III. The diffusible calcium of the blood serum in allergic diseases.** *Arch. Internal Med.* 46(1): 72-74. 1930.—Analyses of the serum in 14 cases of allergic disease show values for diffusible Ca that vary within the normal range. Other data collected by the authors indicate that except in diseases in which there is a marked reduction in serum proteins (which causes abnormal variation in the non-diffusible Ca), physiologic variations in the Ca occur ordinarily in the diffusible Ca fraction, often with little concomitant variation in the total Ca values, as shown strikingly in the tetany of parathyroid deficiency. Hence the observation that the total and diffusible blood serum Ca vary together within the normal range in allergic diseases indicates that physiologically available Ca is present in the blood in adequate amounts.

7292. **GUBIN, W. M., und R. B. GOLDINA. Ueber die aktuelle Reaktion der Hirnsubstanz bei experimenteller Tollwut.** *Zentralbl. Bakt. I. Abt. (Orig.)* 116(1): 76-80. 1930.—The various parts of the brain of the normal guinea-pig and rabbit showed some differences in pH, but were on the whole weakly alkaline, almost neutral. Intracerebral infection of a series of rabbits (number not stated) with fixed virus of rabies produced by the 3rd day an acidification of the brain reaction which was unchanged until the 6th day, when an alkalinization set in, reaching its maximum on the 8th day (day of death). Subcutaneous infection of 5 guinea-pigs with a fatal dose of tetanus bacilli produced weak acidification of the brain substance on the 2nd day; on the 3rd day (day of death) it became alkaline again.—*Author summary (transl.).*

7293. **GUNTHER, LEWIS, and DAVID M. GREENBERG. II. The diffusible calcium and the proteins of the blood serum in malignant diseases.** *Arch. Internal Med.* 46(1): 67-71. 1930.—Following out the suggestion that abnormal Ca metabolism may be concerned in neoplastic development, Gunther and Greenberg determined total and diffusible Ca in the sera of 15 patients. Their observations indicate that the diffusible Ca is within the limits of normal variations in malignant diseases. If the diffusible Ca may be considered a measure of the physiologically available Ca, it may be concluded that it is present in adequate amount in malignant disease, and that the blood Ca is apparently not a factor in the etiology of such disease.

7294. **GUREWITSCH, N. A. Über den Kreislaufshock bei dem akuten Darmverschluss.** *Arch. Klin. Chir.* 154 (3): 584-596. 7 fig. 1929.—The lower intestinal content (after definite methods of preparation) of normal dogs and the blood serum and stomach content of dogs after

acute intestinal obstruction cause a decrease in the perfusion rate through the isolated rabbit's ear, a fall in blood pressure and a dilatation of the skin capillaries in a manner entirely analogous to the action of histamine. The intestinal contents above the obstruction from living animals do not cause these phenomena, but the same contents 4 hours after death produce the circulatory changes. There is a progressive fall in blood pressure after acute obstruction and this is paralleled by an increase in the coagulability of the blood. The therapeutic use of large amounts of isotonic saline before and after operation is recommended. Acute verrucose endocarditis was observed in 7 of 12 animals with acute intestinal obstruction of 4 to 7 days duration.—*R. A. Moore.*

7296. **HANDLEY, W. SAMPSON. Lymph-stasis the precursor of cancer.** *Brit. Med. Jour.* 2(3587): 607-611. 17 fig. 1929.—Cancer is an ativistic reversion of certain cells of the body to the state of their one-celled ancestors. The cancer cell is living among the body cells as a parasite. It is an anarchist in the body politic representing either a spontaneous reversion or a product of disorders. Origin of cancer is intimately associated with local lymphatic obstruction. This must have lasted for 20 to 30 years. As seen in cancer following x-ray, epithelial hyperplasia follows an obliterative lymphangitis. Change in connective tissue precedes development of tar carcinoma, thus a lymphatic obstruction followed by papillary hypertrophy is the precursor of papillomatous formation which frequently precedes cancer. Author cites frequency of lupus carcinoma and tuberculous origin of intestinal and vesical polyposis. Papillary hypertrophy precedes many breast cancers, especially of the duct type. Papillary hypertrophy occurs only when the central lymph vessel of the papilla blocks, stasis occurs, supply of O and hormones (growth inhibitors) is blocked. This chronic lymphatic block or lymphangitis may be caused by tuberculosis, syphilis, pyogenic infections, or many of the agents which have been considered as irritants.—*L. H. Jorstad.*

7297. **HASSIN, GEORGE B. Hydrocephalus: studies of the pathology and pathogenesis, with remarks on the cerebrospinal fluid.** *Arch. Neurol. & Psych.* 24(6): 1164-1186. 16 fig. 1930.—Hassin criticizes previous explanations of the cause of hydrocephalus as based on anatomy rather than histology, and results of experimental work on the subject as not in agreement with observations in clinical cases. In 12 cases of hydrocephalus of the so-called communicating type large amounts of fluid were observed to coexist with a deficient or defective choroid plexus. Hassin therefore concludes, in opposition to Dandy and Blackfan, that the choroid plexus is not responsible for hydrocephalus, which is but a partial manifestation of a hydropic condition of the brain, of which such phenomena as distention of the subarachnoid spaces and rarefaction of the cerebral tissues are probably more important and sometimes the sole manifestations; that the sole avenue of escape or absorption of the cerebrospinal fluid is from the subarachnoid spaces by way of their prolongations along the perineural spaces of the cranial nerves and spinal roots; and that occlusion of the cisterns and the perineural spaces of the cerebral nerves preventing the escape of fluid, may be an important factor in the production of hydrocephalus.

7298. **HELLNER, HANS. Ergebnisse der Übertragung menschlicher Geschwülste auf Mäuse.** *Arch. Klin. Chir.* 161(1/2): 1-48. 23 fig. 1930.—This work was undertaken 2 yrs. ago to test the conclusions of Heidenhain, who had reported the production of carcinomata and sarcomata in mice by use of autolysates of human tumors. Hellner injected autolysates and fresh tumor pulp into 381 mice, and obtained 14 tumors, or 3.7%. Of 327 controls, 7 developed tumors (2.77%). Of the controls, 176 had received injections of embryonic extract or other tissue; 5 of these (2.8%) developed tumors, while of the uninjected controls 2 (1.3%) developed tumors. Hellner concludes that the difference between the percentages of tumor developing in experimental animals and controls (3.7% against 2.2%) is too small to justify deductions as to the part played by the autolysate, particularly since the autolysate tumors are not distinguished in any way from spontaneous tumors, and occur in percentages no higher than those for spontaneous tumors.

7299. **HERRMANN, FRANZ. Harnsäureuntersuchungen bei Psoriasis.** *Arch. Dermatol. u. Syph.* 161(1): 114-126. 1930.—Different methods of determination of the uric acid content of the blood serum gave varying results. Numerous comparisons showed that the Benedict method is the most suitable provided that the NaCN solution used is freshly prepared each day. A total of 179 individuals were examined. Of 140 patients with psoriasis, 44 showed a serum uric acid of 5 mgm.% or more. Thus in 31.4% of the patients a uric acidemia was found. An increase is observed most frequently in patients with arthritis psoriatica. A considerable percentage of the patients with retention of serum uric acid showed a retarded uric acid elimination in the urine, therefore a lower urine/blood uric acid ratio. In 50% of the cases "Ambard's Constant" for uric acid (Steinitz) was .07 and more. No relationship between psoriatic skin manifestations and the serum concentration of uric acid could be established. The cause of the increased serum uric acid and its relation to psoriasis is unknown. The observation of Scherk that there is a difference in the uric acid content of blood serum and bullae produced by cantharidinum could not be confirmed.—*Author's summary (transl. by J. A. Gammel).*

7300. **HESS, ALFRED F., MILDRED WEINSTOCK, H. RIVKIN, and J. GROSS. The lack of relationship between the development and cure of rickets and the inorganic phosphorus concentration of the blood.** *Jour. Biol. Chem.* 87(1): 37-46. 1930.—Rickets may be associated with normal concentrations of inorganic P in the blood. If milk is incorporated in a standard rickets-producing ration, a peculiar chain of circumstances can be brought about. On the addition of small amounts of irradiated ergosterol, the inorganic P is raised to the normal level without accompanying signs of healing of the rachitic lesion. Animals which receive supplements of cod liver oil do not attain as high a concentration of P but do show definite evidences of healing. Of course, if full doses of irradiated ergosterol are given, prevention or cure can be relied upon. Irradiation may elaborate a factor which increases the inorganic P in the blood, quite apart from any antirachitic action. This paradoxical phenomenon—a rise of inorganic P unaccompanied by a healing of the epiphyses—shows that although rickets usually is associated with a decrease of the inorganic P of the blood, this diminution cannot be regarded as an essential or inherent feature in the pathogenesis or the healing of this disorder. In addition to the systemic disturbance characteristic of rickets, there is probably a local disturbance at the epiphyses which prevents the anchorage of Ca and P in cartilage and bone.—*Authors' summary.*

7301. **HIEGER, IZRAEL. The spectra of cancer-producing tars and oils and of related substances.** *Biochem. Jour.* 24(2): 505-511. 2 pl. 1930.—The fluorescence spectra of many cancer-producing substances show the same bands at wave-lengths 4000, 4180 and 4400 Å. These bands are quite similar to those of the fluorescence spectrum of 1:2-benzanthracene. The absorption spectra in the ultra-violet lend support to the view that there is some connection between the cancer-producing substances and 1:2-benzanthracene.—*E. B. Carmichael.*

conclude that in chronic lead-poisoning as in congenital hematoporphyrinuria an increased destruction of erythrocytes furnishes a supply of hemoglobin as mother substance of the hematoporphyrin.

7303. **HORSTERS, HANS.** Studien über den Diabetes mellitus des Menschen. I. Mitteilung. Über den Phosphat-Kohlenhydratstoffwechsel beim Diabetes mellitus (nach experimentellen und klinischen Untersuchungen). *Zeitschr. Ges. Exp. Med.* 66(1/2): 89-128. 1929.—Studies of the carbohydrate-phosphoric acid balance in diabetes mellitus depend on the quantity of insulin. In most instances insulin causes an increase of the CH-PO_4 balance. Often moderately severe and severe diabetics which show a negative K-H-PO_4 balance without insulin become positive on insulin and in proportion to the quantity of insulin up to a certain optimum which varies for every patient. Insulin can activate the utilization of the carbohydrates through the activation of phosphates.—*H. Horsters (transl. by H. J. John).*

7304. **HORSTERS, HANS, und HEINRICH BRUGSCH.** Insulinstudien. III. Mitteilung. Über den Insulingehalt menschlicher Organe beim Diabetes mellitus. *Zeitschr. Ges. Exp. Med.* 66(1/2): 143-156. 7 fig. 1929.—In diabetic patients who died from various causes, one finds (also in coma, diabetic coma) in the organs a relatively large quantity of insulin. Insulin deficiency alone cannot be the cause of diabetes. There must be in a diabetic a faulty distribution of insulin; the insulin in diabetes does not reach its necessary physiological substratum to enable it to act.—*H. Horsters (transl. by H. J. John).*

7305. **ICHIMI, TAKEO.** Über Adrenalinempfindlichkeit des Blutdrucks und des Blutzuckerspiegels bei Hypertonikern. *Tohoku Jour. Exp. Med.* 13(5/6): 405-423. 6 fig. 1929.—The author refers to the accumulated evidence demonstrating the sensitivity of the blood pressure in hypertensives as compared to normal individuals, and to the absence of information respecting the effect of small doses of adrenalin on the blood sugar in hypertensives. His investigations lead to the following conclusions. In benign hypertension there is a slightly increased adrenalin sensitivity, very seldom inverse; with malignant hypertension it is also increased. In secondary renal atrophy a preliminary lowering of blood pressure is followed by a rise. In uremia the adrenal sensitivity is diminished sometimes below the normal. The blood sugar in general is increased in hypertensives, especially in those that have azotemia. Intravenous injection of minimal adrenalin doses yields blood pressure fluctuations in hypertensives of all forms that can not be considered typical.—*W. F. Jacobs.*

7306. **ITO, WASHIMI, ICHIYA SEKI, und FUSAKICHI NAKAZAWA.** Studien über den kolloid-osmotischen Druck des Bluts bei normalen und pathologischen Zuständen. I. Kolloid-osmotischer Druck des Bluts bei Lungentuberkulose. *Tohoku Jour. Exp. Med.* 14(2/3): 254-264. 1929.—The author prefaces his study by citing the established evidence that in tuberculosis there is an increased rapidity in the sedimentation reaction of the blood while the manner in which this occurs is not clear. The normal colloidal osmotic pressure was found to range between 40.5 and 49.5 with an average of 46.5. In 1 series of moderately advanced tuberculosis the range was 48.1 to 40.1 with an average of 42.9. In a 2nd series the range was 39.9 to 30.6 with an average of 37.6. Summarizing the study of normal Japanese, the average colloidal osmotic pressure was 385 mm. of water pressure and about 46.2 per 1% serum albumin. In moderate tuberculosis normal values were approximated. In severe tuberculosis reduction to 301 mm. of water with colloidal osmotic pressure mm. per 1% serum albumin, 40-30.—*Wm. F. Jacobs.*

7307. **JACOBY, M.** Betrachtungen über Proteolyse und Carcinom. *Zeitschr. Krebsforsch.* 32(1/2): 107-109. 1930.—Jacoby points out that by the application of recent methods to the study of proteolysis in cancer,—the recognition that between a complex protein and its final cleavage into amino-acids there intervene a whole series of separate enzyme actions,—it should be possible to add greatly to our knowledge not only of the ferments of cancer, but of its nature as well by the qualitative and quantitative study of the ferments themselves, and of known ferments acting on cancerous tissue as a substrate.—*H. E. Eggers.*

7308. **JACQUEMART, L., et CH. PFEIFFER.** Tréponème et Néoplasmes. 165p. N. Maloine: Paris, 1927. Pr. 15 fr.—The authors maintain on purely clinical and speculative grounds, with no experimental evidence other than observations of Carrel, Gye, and others, which they reinterpret as supporting their conclusions, that:—All tumors, cancerous or non-cancerous, benign or malignant, are due, in man, to syphilis. Human cancers are quaternary syphilides. Early syphilis does not give rise to cancer. The older the syphilis, the more cancerogenic it becomes. Early syphilis is the manifestation of the visible, non-sporulated *Treponema*, susceptible to the action of treponemicides. Old and heredo-syphilis are the manifestations of an invisible, sporulated *Treponema*, (of the type of an infra-virus or ultramicroscopic virus), not susceptible to treponemicides. The cancer cell is a product of syphilis. The sporulated *Treponema* infects this cell and causes repeated mitoses, to the point of producing a neoplasm. Syphilis explains cancer families and cancer centers in villages and houses, as well as cancer epidemics. Peoples free from syphilis suffer little or not at all from cancer. The war on cancer therefore resolves itself into a war on syphilis. Tumors of the lower animals are due to infra-viruses, invisible forms of common and visible parasites. Plant tumors are parasitic tumors.—*R. C. Whitman.*

7309. **JEZLER, ADOLF.** Beitrag zur funktionellen Leberdiagnostik. *Zeitschr. Klin. Med.* 111(1): 48-70. 13 fig. 1929.—A review of methods of liver function tests for diagnostic purposes. The author gives several tables of his own results, using the best known methods. The qualitative diazo test, accompanied by a quantitative bilirubin estimation, indicates parenchymatous disorder if the bilirubin is not above 425 mgm. %. The bilirubin excretion value is a simple test for diffuse parenchymatous damages of the liver. Tetrachlorphenolphthalein adds nothing to the value of methods in diagnosis of disorders of liver function. Galactose tolerance tests are of value in differentiating between mechanical and parenchymatous malfunctions of the liver. The changes in reducing power of the blood should be considered as well as the secretion of galactose in the urine. Takata's flocculation reaction is always positive in decompensated cirrhosis of the liver with ascites. It is not known that this test is specific.—*D. R. McCullagh.*

7310. **JOLTRAIN, E., T. KÉVÉSZ, et R. WOLFF.** Cancer et troubles du métabolisme des sucres. *Bull. Assoc. Française Étude Cancer [Paris]* 17(3): 125-138. 3 fig. 1928.—In normal subjects a known quantity of sugar absorbed induces, during the following hours, a marked elevation of the respiratory quotient. From 0.700-0.900 before ingestion, for instance, the quotient rises to 0.960-1.04 after ingestion; ordinarily the highest value is reached at the end of 2 hrs. This shows that the R. Q. of normal persons increases by 15-20%. The same is true of most patients examined. After ingestion of sugar the R. Q. increases in about the same proportion as in normal individuals. An analogous increase was even seen in patients with cachexia with considerable emaciation and in very poor general condition. However, in patients suffering from cancer at whatever point, the R. Q. increases only slightly, or not at all, after sugar ingestion. The greatest increase did not exceed 12%, while it is 16% in normal persons and those suffering from other ailments. This marked difference in changes of R. Q. in normal and other pathologic conditions as compared with cancerous patients is most manifest in the curves we have assembled. These new results show that the cancer patients do not burn their sugar as do normal individuals or those suffering from other diseases. This is another incontestable proof of some disturbance in the sugar metabolism in cancer.—*Authors' conclusions (transl. by B. Bickel).*

7311. **KIRITA, KENZABURO. Experimental studies in gall-stone formation. 4. A contribution to the knowledge of the etiology of gall-stone formation. 1. Studies on the influence of the functions of the autonomic nervous system on gall-stone formation.** *Japanese Jour. Gastroenterol.* 2(1): 41-54. 1930.—Previous work by Ohta dealt in the main with the quantitative estimation of some inorganic constituents in bile and not the changes in the reaction of bile. The present work investigated the H-ion concentration, cholesterol content, surface tension, viscosity and specific gravity of rabbit's liver bile, when autonomic nerve poisons were given, or when a portion of the autonomic nervous system was mechanically stimulated. Stimulation of the parasympathetic nervous system was studied by injecting pilocarpine hydrochloride, electrically stimulating the vagus, and by section of the major splanchnic nerve. The sympathetic system was stimulated by injecting adrenalin hydrochloride and atropine sulphate, electric stimulation of the splanchnic ganglion and by section of the vagus. In the latter series the pH of the bile tends to decrease, while in the former it increases, suggesting an intimate relationship between the function of the autonomic nervous system and the formation of gall-stones. The cholesterol content, specific gravity and viscosity of bile were changed, suggesting that when the parasympathetic system is excited, bile is concentrated, affording strong evidence of intimate relationship between the function of the autonomic nervous system and gall-stone formation. Increased concentration and total quantity of cholesterol in the bile seem especially important as a factor in lithogenesis. The surface tension of bile changed, but its relation to stones is not clear.—*B. C. Russum.*

7312. **KLAUDER, JOSEPH V., and HERMAN BROWN. Experimental studies in eczema. V. Studies of the potassium, total and diffusible calcium ratios in the blood of patients with diseases of the skin.** *Arch. Dermatol. & Syphilol.* 22(5): 877-892. 1930.—Eleven determinations were made of the K-Ca ratio in 8 normal persons. The total serum Ca ranged from 9.5 to 12.8 and the K from 19.1 to 24. The K-Ca ratio was within a normal range, 1.72-2.08. A total of 120 determinations of total serum K and total serum Ca and diffusible Ca was made in patients with different diseases of the skin. From these data the percentage diffusible Ca of total Ca, the K-Ca ratio and the K-diffusible Ca ratio were calculated. In 107 patients with 24 different diseases of the skin the K-Ca ratio was within normal limits in 78 patients, and an abnormal ratio ranging from 2.11 to 2.46 was observed in 29 patients with 11 different diseases of the skin. The following figures were regarded as within normal limits: total serum Ca, 9-11; total serum K, 18-20; percentage of diffusible Ca of total Ca, from 45-55%; K-Ca ratio up to 2.10; K-diffusible Ca ratio, from 3.50-4.50. There was no disease of the skin in which the K-Ca ratio was uniformly altered in all patients.

7314. **KYLIN, ESKIL. Studien über den kolloidosmotischen Druck. VII. Über den kolloidosmotischen Druck des Blutserums bei Diabetikern, besonders während der Insulinbehandlung. VIII. Der kolloidosmotische Druck des Blutserums bei Morbus Basedowi und Myxöden.** *Zeitschr. Ges. Exp. Med.* 72(5/6): 650-658. 5 fig.; 659-665. 1930.—VII. The values for the colloid-osmotic pressure of the blood-serum in 20 diabetics lay in general within the normal, but frequently on the upper border. The average pressure for the 20 was in general 19 mm. H_2O higher than those found in normal cases. During insulin treatment of the diabetics the colloid-osmotic pressure sank distinctly, and (with one exception) an accumulation of water became, a little later than the fall in pressure, a clinically recognizable edema. Kylin presents reasons against the theory that insulin edema is produced by fall in colloid-osmotic pressure.—VIII. The colloid-osmotic pressure in 15 cases of Basedow's disease was often (and especially in the most refractory cases) subnormal, the average for the 15 being near the lowest normal value. During improvement of 3 Basedow cases under x-ray treatment the colloid-osmotic pressure rose to normal. In both of 2 untreated cases of myxedema the colloid-osmotic pressure was high, in 1 case about on the upper limit of the normal, in the other far above. Under thyroid treatment the pressure in both cases sank decidedly, indicating a reducing effect by the thyroid hormone on the colloid-osmotic pressure.

7315. **LAKHOVSKY, GEORGES. À propos de la théorie étiologique du cancer basée sur la nature biologique du sol.** *Rev. Gén. Sci. Pures et Appl.* 39(12): 357-362. 1928.—Cancer preferentially develops in districts where the soil is clay or alluvial, rather than those where the soil is sand or sandstone. Soil is the underlying cause of cancer while injury may be the accidental cause. The cosmic rays are absorbed to a depth of 100 meters. In soils such as sandstone they are reduced to ½ of their amplitude at a depth of 80 meters. Conflicting theories are discussed.—*Z. E. Taylor.*

7316. **LEITES, S., und D. EBITSCH. Zur Charakteristik der Stickstoffwechseldynamik bei Tuberkulosekranken.** *Beitr. Klin. Tuberk.* 75(5/6): 662-675. 1930.—As a stimulus peptone was fed and the curve of the residual N in the blood and the N of the urine served as the index of reaction. In all, 63 determinations after feeding 43 patients and 7 determinations after feeding clinically healthy subjects, were made. The following types of reactions were noted in tuberculous patients: (a) Direct reaction: elevation of the residual N of the blood; N of the urine unchanged or elevated. (b) Inverse reaction: residual N reduced; N of the urine either unchanged or diminished. (c) Torpid reaction: only slight changes in the residual N of the blood. (d) Mixed reaction: periods of elevation and diminution of the N of the blood. The inverse reaction of the blood, coupled with a clear-cut, direct reaction in the urine are modifications of a direct reaction, obviously modified by the function of the kidney. The designated types of azotemia and azoturia permit the setting up of 3 main types in the reaction of N metabolism in tuberculous patients, namely: normal, hyper and hypo reactions. The normal reactions run parallel with the compensatory phases, the hypo and hyper reactions constituting the decompensatory phases. Rich nitrogenous diets bring the hypo reactions nearer the normal; the decrease of protein in the diet bringing the hyper reactions nearer the normal. Obviously the character of the azotemia and azoturia depends on the N reserve of the organism.—*W. W. Herrmann.*

7317. **LENNOX, WILLIAM G., and MARGARET B. ALLEN. Studies in epilepsy. XI. The calcium content of the blood and of the spinal fluid.** *Arch. Neurol. & Psych.* 24(6): 1199-1205. 1930.—Measurements of serum and spinal fluid Ca were made in 77 unselected patients who were subject to recurring convulsions. Average concentrations and average spinal fluid-serum ratios were within normal limits. As compared with measurements in non-epileptic patients there was an abnormally wide distribution of values, with a special tendency toward low spinal fluid measurements. In ⅛ of the patients the ratio of spinal fluid to serum Ca was less than 45%. Only 1 of the patients had clinical tetany.—*Authors' summary.*

7318. **LICKINT, FRITZ. Über den Gehalt des Serums an stickstoffhaltigen Bestandteilen und Kochsalz bei der Prostatahypertrophie zugleich unter Betrachtung der Funktion der hydronephrotischen Schrumpfniere.** *Deutsches Arch. Klin. Med.* 163(1/2): 51-64. 1929.—Conclusions are drawn from 150 cases, for a part of which detailed urinary analyses are tabulated. The concentrating capacity of the kidneys ordinarily suffers before their capacity to excrete N compounds. This latter capacity is impaired, not uniformly, but chiefly for uric

acid and urea, and least for creatinine. From this difference in the excretion capacity it is concluded that the various N compounds are secreted from different localities: the creatinine, which suffers least retention, from the glomeruli, on which the urinary engorgement inflicts least damage; the other urinary constituents from the more seriously injured tubuli.

7319. **LUISADA, A. Ipertensione encefalica ed edema polmonare sperimentale di natura riflessa. [Encephalic hypertension and experimental reflex edema of lung.]** *Boll. Soc. Ital. Biol. Sperim.* 5(4): 528-530. 1930.—In dog and cat the experimental increase of encephalic pressure was accompanied by edema of lungs. The author suggests that edema was produced by nervous reflexes increasing the permeability of the lung vessels.—*M. Comel.*

7320. **McCLINTOCK, JOHN T., and HARRY M. HINES. Occurrence of a toxic proteose fraction in material from various sources.** *Arch. Surg.* 21(5): 860-864. 1930.—A toxic proteose fraction was isolated from normal intestine, obstructed small and large intestine, intestine of animals with obstruction of the portal vein and liver and from tissue allowed to undergo anaerobic autolysis in the presence of intestinal flora. The presence of this fraction was determined by the symptoms, changes in the blood and pathologic processes produced by its injection into dogs. It is suggested that the presence of this toxic material in various pathologic conditions should be regarded as indicating increased amounts of a material normally present rather than the elaboration of a new and specific substance.—*Authors' summary.*

7321. **MAGAT, J. Phosphatidhaushalt der Krebszelle und des Krebsgewebes. Histochemische Untersuchung des Ehrlichschen Adenocarcinoms.** *Zeitschr. Krebsforsch.* 31(6): 557-564. 1 fig. 1930.—Magat finds that the injection of a stable emulsion of lecithin into tumor animals is followed by the storage of phosphatids in the spleen and in the cancerous tissues, regardless of whether these are living or necrotic. Storage in other sites may take place,—there is evidence for its accumulation in the red cells,—but in a dispersed state which does not lend itself to ocular observation, as is the case with the first-named tissues. It appears that spleen and tumor tissue have an elective affinity for phosphatids, without having the power to effect their intracellular dispersion. Apparently the altered relations of lecithin and cholesterol so usually shown by tumor tissues are to be explained by this phenomenon, as well as their altered physico-chemical properties,—in natural conditions with the phosphatids coming in part from cellular decomposition, in part from the accumulation without dispersion of endogenous phosphatids. Magat suggests the possibility of these substances being used as carriers to tumor tissue of active therapeutic agents.—*H. E. Eggers.*

7322. **MARINO, S. Contributo allo studio delle variazioni quantitative dei lipoidi e dei loro rapporti nel sangue delle anemie sperimentali e cliniche. [The quantitative variations of the lipoids and their ratio in the blood in experimental and clinical anemia.]** *Policlinico [Sez. Med.]* 37(11): 541-556; (12): 566-591. 1930.—Studies on the cholesterol, fatty acids and lipid P in 9 dogs (4 subjected to anemia from repeated bleedings and 5 to anemia by toxic hemolysis) and 18 cases of clinical anemia, showed important variations in the blood lipids and their ratio, but no such significant relation between the total cholesterol: phosphatid ratio and the degree or kind of anemia as some authors believe they have found.

Calcutta* 16(4): 1019-1022. 1929.—Marked fibrosis, thickening and eosinophilic infiltration of submucosa, fibrosis and cellular infiltration of muscularis, together or even singly, are diagnostic in the microscopical determination of chronic appendicitis.—*I. Davidsohn.*

7324. **MERTENS, V. E. Über zwei bisher unbekannte Stoffe im Blut und ihre Beziehungen zum Krebs.** *Arch. Klin. Chir.* 162(Kongressbericht): 341-344. 1930.—The 1st substance, which Mertens calls "pathodyne," is a neutral yellowish-white powder obtained in carcinomatous or sarcomatous tissue. Administered to white mice, it does not act for 2 hrs. or so; then it produces typical convulsions in which the animal lies prone, its eyes closed, its whole body twisting while the paws are raised first on one side and then the other; the agitation increases, the animal rolls and leaps and sometimes goes into opisthotonos, while the temp. falls to about 21°. After about 12 hrs. the animal may either recover or die, having first lain motionless for a long time. The other substance, which Mertens calls "normodyne," is obtained from healthy human blood; it produces in mice convulsive movements and death inside of 5 min.

7325. **MERTENS, V. E. Zigarettenrauch eine Ursache des Lungenkrebses? (Eine Anregung.)** *Zeitschr. Krebsforsch.* 32(1/2): 82-91. 4 fig. 1930.—Mice kept in an atmosphere of cigarette smoke showed 2 cases of bronchial adenocarcinoma, out of 125 animals with which the experiment was started. Only one of these certainly originated during the experiment, and the writer leaves a causal relationship open to question. The animals in general showed various degrees of acute inflammation of the trachea, bronchi and lungs. M. records changes observed in the spleen, skin and intestine. The animals bore no young, but the cause of this was not determined. —*H. E. Eggers.*

7326. **METZLER, F. Experimentelles zum Wundschock.** *Deutsche Zeitschr. Chir.* 228(6): 340-348. 1930. —Experiments (number of animals not stated) involving either laceration of muscle tissue or ligation of extremities for variable lengths of time, using the method of H. Pfeiffer for the determination of peptidase content in the organism, demonstrated that as cause for traumatic shock both a protein decomposition poisoning and a nervous component are operative. Careful avoidance of traumatic shock is essential in operations. This is made possible by operations which spare the tissues and by putting injured regions at rest; to influence the nervous components, by elimination of pain and the use of modern methods of narcocsis, as avertin with nitrous oxide.—*Author's summary (transl. H. M. Zimmerman).*

7327. **MONTEIRO, HERNÂNI. Simpático e vasômotricidade. [The sympathetic and vasomotor action.]** *Portugal Méd.* 1930(4): (3-26). 8 fig. 1930.—The writer studied the rôle of the sympathetic nervous system in vaso-motor phenomena, calling attention to facts which explain various therapeutic effects encountered by surgeons. He describes some anomalies of the cervical sympathetic of surgical importance and has noted the effects of cervical sympathectomies (in dogs and rabbits) on vaso-motor phenomena, temperature, leucocytosis, and the cicatrization of experimental wounds.—*H. Monteiro (transl. by N. D. C. Lewis).*

7328. **NAKAHARA, WARO, and EIICHI SOMEKAWA. Vitamins and tumor growth. IV. On the vitamin B consumption by growing rat tumor.** *Proc. Imp. Acad. [Tokyo]* 6(8): 345-347. 1930.—Of 120 albino rats which had been kept a week on a diet of unpolished rice and water, ½ were inoculated with Fujinawa rat sarcoma, and all were then transferred to a diet (horse meat protein 15%, starch 65%, butter 15%, McCollum's salt mixture 5%) deficient in vitamin B. All were killed 2 weeks later, and the vitamin B content of the livers of sarcomatous and healthy rats (dried at 80° C) was assayed by feeding to young albino rats on the above vitamin B-deficient diet. Results showed that the livers of tumor-bearing and healthy rats were not significantly different in the amount of vitamin B reserve. The authors conclude that growing tumors do not consume vitamin B in the body of the host. These results confirm those previously obtained with Rous chicken sarcoma.

7329. **NEAL, M. PINSON, and MAX M. ELLIS. Etiological factor of fat necrosis.** *Southern Med. Jour.* 23(4): 313-320. 5 fig. 1930.—A lipase fraction has been

isolated, by accredited chemical methods, from fresh hog's pancreas, dried pancreatin and the dried seeds of *Arachis*, the peanut, and *Helianthus*, the common sunflower. Each of these lipase fractions produced definite fat necrosis when injected intraperitoneally into white rats. These lipase fractions: (a) Were not thermostabile, and were rendered inactive, in so far as the production of fat necrosis was concerned, by treatment with ethyl alcohol in strengths above 50%. (b) Were water soluble and were not injured by the presence of ether, toluene, or xylol. (c) Were not adsorbed by blood or animal charcoal from either acid or alkaline solutions. (d) Were extracted from both acid and alkaline material. (e) Did not digest fibrin, but were active in splitting ethyl butyrate. Histologic lesions of fat necrosis were found 6 hrs. following injections of the lipase fraction derived from *Arachis*. There was damage to cell walls, cytoplasm, nuclei, and cell fat content. Loss of nuclear material within 6 hrs. after injections showed the critical character of the process. The lesions were demonstrable 8 days after injections of the *Arachis* material. Anatomic lesions were found 16.5 hrs. after injections of the lipase fraction from hog's pancreas. There were no definite clinical manifestations in the animals injected. The assumption of Langerhans that lipase is an etiological factor of fat necrosis has been proved experimentally by the use of lipase fractions derived from animal and vegetable materials.—*From authors' summary.*

7330. **NEUBERG, C., M. KOBEL, und H. LASER. Über den Mechanismus der Zuckerspaltung im Tumor und embryonalem Gewebe.** *Zeitschr. Krebsforsch.* 32(1/2): 92-98. 1930.—By the extraction of rat sarcoma tissue with alcohol and ether or acetone a dried preparation was obtained containing active glycolase. In this procedure the co-ferment is so inactivated or destroyed that in the action of the tumor preparation on hexose-phosphate the methylglyoxyl produced is not utilized, and is accumulated. Some of the methylglyoxyl, however, is affected, or added methylglyoxyl disappears, so that the mode of lactic acid formation in tumors is similar to that of other glycolytic systems. Similar results were obtained with embryonic tissues.—*H. E. Eggers.*

7331. **NOTKIN, J. Basal metabolic rate in untreated and treated patients with epilepsy.** *Arch. Neurol. & Psych.* 24(6): 1231-1237. 1930.—The basal metabolic rate in a group of 50 untreated epileptic patients (29 women and 21 men) was normal in a high percentage in both sexes; Notkin's observations showed a relatively smaller group of patients with a rate below −10 than the reports of some other workers; there is a higher percentage of below −10 readings in the ♀ group than in the ♂ group. No correlation could be established between the chronological age and the basal metabolic rate. The basal metabolic rate in a group of 16 epileptic patients treated with phenobarbital showed a considerable decrease in the percentage of normal readings and a threefold increase of the percentage of readings below −10. He concludes that phenobarbital definitely decreases the basal metabolism. The basal metabolic rate of a group of 26 patients treated with bromide showed no rate above the normal range, a decrease in the percentage within the normal range and an increase in the percentage of the lower readings. A comparative study of basal metabolism in a group of 12 patients before treatment and during the course of treatment with bromide tends to show a decrease, with only a few exceptions. The decrease is marked in some instances.—*Author's summary.*

Sperim.* 5(4): 510-514. 1930.—Following administration of tyrosin, Millon's reaction and Buscaino's Ag nitrate reaction were found positive in blood and urine in some cases of dementia praecox, the reactions being given by substances of the phenol group.—*M. Comel.*

7333. **OHTA, RYUICHI. Experimental studies in gall-stone formation. 2. Alkali and alkaline earth and metal content in bile. 3. Effect of abnormal functioning of the vegetative nerve system on alkali and alkaline earth metals contained in bile.** *Japanese Jour. Gastroenterol.* 2(1): 19-40. 1930.—Studies were made on the relations between the quantities of Ca, Na, K, and Mg in bile when the chlorides of these metals are injected into the blood. Bile was collected for 4 hrs. through a biliary fistula and the quantities of the metals excreted determined. It was shown that these metals are excreted by the liver and not by the gallbladder; they are increased in the bile after intravenous injections. The effects of the injection of a chloride of one of these metals on the distribution of the other kinds of alkali and alkaline earth metals in bile was also studied. When NaCl was injected, the content of the metals showed no marked difference from the normal but when the chloride of any other metal was injected, varying increases followed, with changes in the distribution of metals in bile. By raising the concentration of the chloride of one of these metals in the blood, a change was also produced in the distribution of the other metals in the bile. The process is not understood. To properly investigate changes in amounts of substances in bile, observation must be conducted on single animals, since there are marked individual differences in the quantity of hepatic bile excreted by rabbits. The normal concentration of K, Na, Ca, and Mg in bile has the following average ratio: K: Na: Ca: Mg = 6: 180: 6: 1. The hypothesis is advanced that in conjunction with various other conditions that tend to raise concentration of these metals in the blood, the injection of the chloride of one of these metals promotes biliary concretion.—3. To clear up doubt concerning the relation of gall stones to abnormally contracted bile ducts and qualitative changes in bile caused by abnormal functioning of the vegetative nerve system, studies were made on the changes in the quantities of alkali and alkaline earth metals in rabbit's bile after injecting autonomic poisons and applying mechanical stimuli to certain parts of the autonomic nervous system. Animals and methods of securing bile were those described by the author in his Report No. 2 detailing studies of the alkali and alkaline earth metal content in bile. By injecting pilocarpine, electric stimulation of the vagi, and section of the splanchnics, thereby impeding the sympathetic, there were quantitative changes in bile collected from the liver, with increased total content and concentration of Ca and K. Ca showed the most marked change. Injection of pilocarpine hydrochloride increased the total content and concentration of Mg, while with the various stimuli the quantity of Na was unchanged. The content of the metals was not due to condensation of bile. It is concluded that a certain change is produced in each of these metals in the blood when the above-mentioned stimuli are applied; the changes in the quantities of these metals in the bile are secondary. With sympathetic stimulation hepatic bile was decreased, while the metals in the bile tended to decrease in total quantity, and all except Na decreased in concentration. These changes were not due to condensation of bile. Since metals have a precipitative effect on hydrosols of bilirubin and cholesterol it is thought there is an intimate relation between the function of the vegetative nerves and gall-stone formation. The fact that Ca, which has a powerful condensing influence on both hydrosols, was most markedly increased in total content and concentration in bile when the parasympathetic was stimulated, points to augmented function of the vagus as a factor in biliary concretions. It is thought that the lithogenesis is caused by quantitative changes in bile due to stimulated function of the parasympathetic, but not to abnormal contraction of the bile ducts as Westphal thought.—*B. C. Russum.*

7334. **PARTOS, ALEXANDER, und FRANZ SVEC. Regulation des Kohlehydratstoffwechsels. V. Die syner-**

getische Wirkung der Milchsäure auf das Insulin. *Pflüger's Arch. Ges. Physiol.* 222(3): 287-292. 1929.—Human blood corpuscles take up increased amounts of glucose from plasma of rabbits which have received a lactic acid injection. Rabbit blood corpuscles take up no glucose from rabbit plasma or glucose-salt solution, but do so when the plasma comes from a rabbit injected with lactic acid or a glucose-salt solution to which lactic acid has been added. The paradoxic behavior of lactic acid injected simultaneously with insulin (instead of compensation, a more intense hypoglycemia than from injection of insulin alone), previously observed by Partos, is thus explained as due to increase in the capacity of the blood cells to absorb glucose.—*A. Partos (transl. by G. T. Cori).*

7335. **PINNER, MAX, and GEORGINE MOERKE (in collaboration with D. H. SALEY). Pleural effusions. Laboratory findings and clinical correlations.** *Amer. Rev. Tuberc.* 22(2): 121-183. 2 fig. 1930.—Experiments on rabbits show that the normal pleura is highly permeable in either direction for the constituents of the blood. In patients under pneumothorax treatment for pulmonary tuberculosis and with pleural effusions, a marked decrease of the pleural permeability is shown by actual experiments and must be assumed to exist from the results of chemical studies of the blood and the pleural effusion. In 16 such patients, 32 specimens of pleural fluid and blood were examined chemically. The results, more complete than any heretofore reported, are discussed particularly from the standpoint of pleural permeability. Cytological, bacteriological and serological studies on these 32 specimens are reported. Neither chemical, nor cytological, nor serological data afford per se dependable diagnostic or prognostic criteria. The failure of resorption of pleural effusions cannot be explained by their chemical constitution; it must be due to an alteration in the pleural permeability.—*Authors' summary.*

7336. **PITTS, HERMAN C., and HELEN R. JOHNSON. A comparative study of body fluids in cancerous and non-cancerous individuals.** *New England Jour. Med.* 202(9): 415-423. 1930.—The blood serum of cancer patients contains essentially the same amounts of K, Ca and Na and has the same pH as non-cancerous serum, although the pH and K are perhaps a bit higher in the cancer cases. In the blister fluid of cancer patients the Ca and pH are lower and the K and Na higher than in non-cancerous individuals. The Ca of the blister fluid of tuberculosis patients is higher than that of normal or cancer cases. Cancer is not more prevalent in individuals of any one blood type than in any other.—*Authors' summary.*

7338. **POLAYES, S. H., E. HERSHEY, and M. LEDERER. Postmortem blood chemistry in renal disease.** *Arch. Internal Med.* 46(2): 283-289. 1930.—From a postmortem study of the creatinine and urea contents of blood specimens in 100 cases, the following conclusions may be made: Blood creatinine determinations are often helpful as an aid in determining the status of the renal function during life. The urea values are less helpful. A creatinine content of 4 mgm. or more per 100 cc. of blood obtained post mortem indicates marked creatinine retention during life and therefore severe renal insufficiency.—*Authors' conclusions.*

7339. **PYBUS, F. C., and H. T. FAWNS. The effect of variations in the media on the growth of normal and malignant tissues in vitro.** *Journ. Path. & Bact.* 34(1): 39-44. 1931.—Pregnant serum is shown to have a growth stimulating effect on tissues grown in it. A technique is described whereby the growth promoting properties of tissue extracts, etc., may be compared with each other, and experiments with embryo and testis extracts are cited as examples. Pre-heating the media at 55° C. for ½ hr. favoured the growth of carcinoma but retarded the growth of normal embryonic tissues irrespective of whether complement was added to the media after heating or not. Embryonic heart and kidney were used as the normal tissues and mouse carcinoma (I. C. R. F. No. 63) as the malignant.—*H. T. Fawns.*

7340. **RICCI, ALFREDO. Zolfo e glicemia. [Sulphur and glycemia.]** *Policlinico [Sez. Med.]* 37(12): 561-566. 1930.—In healthy subjects Ricci found 0.07-0.10 cgm. S per liter blood serum; in 4 pulmonary tuberculosis patients (1 with diabetes also), 0.06-0.07 cgm.; in 3 diabetes patients, 0.05-0.08 cgm. Intramuscular injection of 1 mgm. colloidal S slightly increased the blood S; the time of elimination by the kidneys exceeded 24 hrs. In 2 diabetic cases the respiratory quotient and blood sugar were studied after injection of colloidal S; the respiratory quotient (which is regularly lower in the diabetic than in the normal subject) was raised, and the blood sugar was lowered. Ricci concludes that S hastens the combustion by which the blood sugar is consumed.

7341. **RICHTER, L. E. Der ausgestorbene Schornsteinfegerkrebs.** *Zeitschr. Krebsforsch.* 31(6): 565-569. 1930.—Chimney-sweeps' cancer, reported with some frequency in Germany a number of years ago, is now practically non-existent in that country. Richter believes that it resulted from a combination of chemical, mechanical and thermal irritation, and that its disappearance is to be explained solely by the greater cleanliness now observed by chimney-sweeps there. It has not disappeared nearly so completely in England, where it always was more frequent—apparently these facts being due to properties of English coal.—*H. E. Eggers.*

7342. **RIDDLE, MATTHEW C. Pernicious anemia: blood regeneration during early remission.** *Arch. Internal Med.* 46(3): 417-439. 1930.—From evidence collected from a group of 68 patients with pernicious anemia undergoing remission as a result of liver treatment and from a consideration of the theoretical factors that influence blood-regeneration under these circumstances, it appears that the magnitude of the reticulocyte response is governed directly by the dosage of the active principle contained in liver. As the magnitude and the rate of the reticulocyte response are to a certain extent interdependent, the condition of the bone-marrow apparently influences indirectly the rate of the response, and the dosage of liver used influences indirectly the magnitude of the response. The percentage of reticulocytes expected, on the average, at the peak of the reticulocyte response can be formulated in terms of the concentration of erythrocytes before treatment. The equation $R = 0.73 - 0.2E_0/0.73 + 0.8E_0$ which represents this relationship can be used in determining the efficiency of treatment and in testing the potency of extracts of unknown value. For 4 patients whose collected data were satisfactory for mathematical analysis, the blood regeneration was formulated according to an equation used by Robertson to express a general law of biologic growth and regeneration. When the rate at which the reticulocytes in the blood of these patients were transformed into mature erythrocytes was estimated by this equation, the curve representing the concentration of reticulocytes during the reticulocyte response could be duplicated mathematically. It was estimated in these patients 2 days were required for the differentiation of reticulocytes in the blood into mature erythrocytes. In 2 other patients in whom the stimulus to regeneration of blood was less intense, it was estimated that between 3 and 4 days were required for the maturation of reticulocytes in the blood to their mature form. A correlation of the relative maturity of the reticulocyte with the amount of reticular material it contained showed that, under the circumstances present, reticulocytes containing small amounts of reticular material disappeared during the following day. When the amount of reticular substance in a reticulocyte was used as a standard for estimating its degree of maturity, it was found that during the early part of the reticulocyte response reticulocytes were liberated in an earlier stage of development than toward the end of the re-

sponse. The rate at which reticulocytes are liberated from the bone-marrow into the blood appears to be a factor of importance which influences the rate and magnitude and velocity of the reticulocyte response. The rate of the liberation of the reticulocytes into the blood seems to be proportional to the rate at which they are formed from the more primitive red blood cells within the bone-marrow and to the numbers of reticulocytes being formed there. An increase of a million red blood cells per cubic millimeter of blood is accompanied by an excretion of approximately 10 gm. of endogenous uric acid in patients with pernicious anemia during early remission.—*Author's summary.*

7343. **RIECKER, HERMAN H., with the technical assistance of MARY E. WINTERS. Iron metabolism in pernicious and in secondary anemia.** *Arch. Internal Med.* 46(3): 458-469. 1930.—It had already been known that a partly diffusible Fe compound present in blood serum is increased in hemolytic diseases of the blood and decreased in the presence of long-continued hemorrhage or a dietary deficiency of Fe. In 19 cases of pernicious anemia the level of the serum Fe usually was higher than normal but became normal during remissions in the disease. A remission in pernicious anemia was accompanied by an increase in excretion over the intake of Fe, as determined by analyses of stool and urine. In 20 cases of secondary anemia, as marked Fe starvation was rarely found as in experimental hemorrhage in animals on a diet low in Fe.

7344. **RIEDER, W. Die Bakterienausscheidung der Niere infolge Gefässschädigung und ihre Beziehung zum vegetativen Nervensystem.** *Arch. Klin. Chir.* 162(Kongressbericht): 695-700. 1930.—It had previously been shown by Müller and Petersen that organs and tissues are receptive to infections during vascular contractions of vegetative origin, as in fever, ague and chilling. To test this theory by interruption of the autonomic nervous supply, Rieder and Müller denervated one kidney in animals (kind and number not stated), the kidney being chosen as a bilateral organ which could be left normal on one (control) side. A bacterial suspension was instilled into the femoral vein by the drop method for 18-24 hrs. about 14 days after the operation. Urine and blood were repeatedly examined. The urine remained sterile for 40-60 min. after the production of bacteremia. At length, after contraction of the cutaneous and renal vessels, albumin, blood and bacteria appeared in the urine on the normal side, while water secretion was decreased. On the operated side the urine remained sterile, clear and free from blood and albumin up to the 17th hr., and the water secretion was unchanged, though urea and creatinine were excreted much more abundantly than on the unoperated side. In some cases, isolated bacteria and a little blood and albumin appeared in the urine on the denervated side toward the 24th hour. If the animals were chilled by ice packs, albumin, blood and bacteria appeared immediately (instead of after 40-60 min.) in the urine from the unoperated side, while on the denervated side the urine remained normal. Rieder concludes that, contrary to accepted views, organs with a vegetative nervous supply are especially receptive, so long as they are in vascular contraction, toward bacteria circulating in the system, the local cell activity being damaged and rendered less resistant by O insufficiency induced by the vascular contractions. This throws light on the origin of acute hemorrhagic nephritis and on the connection between chill and infection.

7345. **RIEHM, W. Experimentelle Übertragung eines lokalen Überempfindlichkeitszustandes von einem paarig angelegten Organ auf das andere, zugleich ein Beitrag zur Genese der sympathischen Ophthalmie.** *Deutsche Med. Wochenschr.* 55(22): 907-910. 1929.—Injection of horse serum in the eye of the rabbit shows that from an immunological standpoint there are various layers in the organism, each susceptible to individual immunization. This newly discovered phenomenon of anaphylaxis explains the origin of sympathetic ophthalmia, which causes in both uveae an "elective tissue sensibility" to either bacterial antigen or to decomposed sarcoma tissues. The same phenomenon no doubt also plays a rôle in tuberculosis and accounts here for the predominating presence of a definite tissue. (Tuberculosis of skin, bones, iris and kidneys.)—*W. Riehm (transl.).*

7346. **ROCCHI, F. Le alterazioni chimiche della saliva parotidea nella parotite epidemica. [Chemical changes in the parotid saliva in epidemic parotitis.]** *Policlinico [Sez. Med.]* 37(11): 509-532. 1930.—In 12 cases of epidemic parotitis the Ca and Cl content of the parotid saliva rose up to the 13th or 15th day, then gradually fell, reaching normal level on about the 27th-30th day from the onset of the disease. The HCNS and the amylolytic power underwent no appreciable changes.

7347. **ROHRBÖCK, FRANZ von, und JOSEF ISTVÁNCSICS. Untersuchungen zum Studium des Zusammenhanges zwischen Blut- bzw. Plasma-Chlor und Magensekretion bei pathologischen Verhältnissen im Kindesalter.** *Jahrb. Kinderheilk.* 119(1/2): 90-99. 1928.—Studies were made on 7 cases of hypo-acid and normal and 10 of hyper-acid gastric content. The conclusions are: Contrary to the findings in adults and infants, the findings of simultaneous determinations of gastric secretions and plasma chlorides in childhood do not run parallel. The cause lies in the fact that the pathologic conditions found in the stomach in childhood are rarely severe. For the determination and recognition of changes in the stomach during childhood, since only orienting values are necessary, the ordinary test breakfast is simplest.—*Author's summary (transl. by W. W. Herrmann).*

7348. **SALOMON, M., et F. de POTTER. La cholestérinémie de la grossesse chex les femmes tuberculeuses.** *Ann. Méd.* 19(6): 587-608. 1926.—In pulmonary tuberculosis cholesterolemia undergoes changes in accordance with the development of the disease. Almost always hypocholesterolemia is seen with great fluctuation of temperature in severe cases rather in accordance with the activity than with the extent, of the lesions. In tuberculous women cholesterolemia shows variations depending on the form of tuberculosis, during pregnancy and after confinement. In inactive tuberculosis changes, such as are seen in the course of normal pregnancy and confinement, are encountered. In active tuberculosis, on the other hand, only slight hypercholesterolemia is seen during pregnancy, with marked and persistent decrease of the cholesterol index after confinement. The amount of cholesterol in the blood may afford an interesting indication for the prognosis of tuberculous pregnant or paturient women. Comparison of allergic reactions and arterial tension with blood cholesterol in pregnant tuberculous women and other tuberculous patients shows that there is no interrelation between cholesterolemia, allergy to tuberculine and arterial blood-pressure.—*Authors' conclusions (transl. by B. Bickel).*

7349. **SCHNEIDER, HERM. Über das Vorkommen und über die Bedeutung von Gewebsgiften bei Shockzuständen des Menschen.** *Arch. Klin. Chir.* 162(Kongressbericht): 561-563. 1930.—The resemblance between histamine shock and traumatic shock has suggested that human traumatic shock may be caused by the presence of histamine or histamine-like substances in the general circulation. Taking the blood-pressure-lowering property of histamine as its most salient characteristic, Schneider sought to determine pharmacologically the presence or absence of histamine in 37 cases (including 23 of traumatic shock, the remainder being burns, postoperative collapse and isolated tissue injuries). He found no trace of any blood-pressure-lowering substance, but in all cases intestine stimulating substances in a concentration which would correspond to a single injection of 12-15 mgm. histamine for the given individual appearing 2-4 hrs. after trauma, reaching its height generally in 12-20 hrs., and disappearing after recovery. Schneider concludes that histamine cannot be the cause of traumatic shock,

but that the connection of the intestine-stimulating constituent of the blood with tissue breakdown is indubitable.

7351. **SILVA-MELLO, A. da. Autochthone Wasserbildung im Körper bei Myxödem.** *Wien. Arch. Inn. Med.* 15(1): 183-194. 1928.—In a typical case of myxedema in an adult thyroid therapy yielded intense effects upon water metabolism in the beginning. This resulted in excessive diuresis with corresponding loss of body weight. Thyroid therapy was particularly effective in the presence of the myxedematous changes even if the doses applied were rather small. The effect of thyroid was altogether different after disappearance of the infiltration. In this stage there is a disturbance of the water metabolism which may be influenced by thyroid but cannot be completely relieved. This disturbance consists in an autochthonous production of water within the tissues, similar to that previously described by the author in genuine nephrosis.—*Author's summary (transl. by M. A. Goldzicher).*

IX. Мед. (*Acta Univ. Asiae Mediae, Ser. IX. Med.*) *No.* 10: 1-5. 1928.

7353. **STEINBACH, M. MAXIM, ALFRED F. HESS, and MILDRED WEINSTOCK. The effect of ultraviolet irradiation on tuberculous peritonitis in guinea pigs.** *Amer. Rev. Tuberc.* 22(1): 35-47. 1930.—The varying therapeutic results of others led the authors to undertake an experimental investigation of ultraviolet therapy in experimentally induced tuberculosis. The procedure consisted of intraäbdominal inoculation into guinea pigs of avirulent tubercle bacilli. One group of animals, 16, received an avirulent strain of tubercle bacilli intraperitoneally, and general irradiation at a distance of 2 feet for ½ hr. every other day. Autopsy found these treated animals with more extensive tuberculous disease, macroscopically and microscopically, than the controls. A second group, 22, was inoculated with 0.01 mgm. of tubercle bacilli; all the animals in this group were treated locally on the shaved abdomen, 10 exposures in all. Subsequently they were given general irradiation. At autopsy the treated animals were found uniformly to have more diffuse lesions than the controls. Because of the poor results obtained in the first 2 experiments, the authors thought that the infecting dose might still be too large, or that the time interval between infection and treatment was too long, or that the animals were very susceptible to tuberculous infection, although they used an avirulent strain not considered highly pathogenic for guinea pigs. With a smaller dose, 0.001 mgm., treatment was begun on the 2nd day after infection. All the animals were also immunized with dead Rl bacilli subcutaneously. By this last procedure they hoped to hold the infection more or less in situ. The guinea pigs (18) were inoculated intraperitoneally; 9 were irradiated, and 9 served as controls. The 9 treated animals once more showed more extensive disease than did those not exposed to ultraviolet rays.—*Authors' summary.*

7354. **STEWART, HAROLD J., and NORMAN S. MOORE. The number of formed elements in the urinary sediment of patients suffering from heart disease, with particular reference to the state of heart failure.** *Jour. Clin. Investigation* 9(3): 409-421. 1930.—From study of 30 cases it appears that the number of casts found in 12 hrs. is usually increased in patients suffering from cardiac disease. If averages are considered, the greatest numbers were passed by patients suffering from heart failure of the congestive type; the numbers were fewer after recovery and fewer still in those who had never suffered from this illness. Granular casts were frequently found. The number of red blood cells in the urine of patients who had experienced cardiac decompensation was frequently greater than the highest normal value, but within the limits in those who had never suffered from heart failure. The average number of red blood cells found in cases which had never experienced heart failure was twice as great as in normal individuals; in those who were suffering from heart failure or had recovered from it, however, the average number was 10-15 times the normal. The number of white blood cells was normal in the urine of patients who had not suffered from heart failure, but the average number was approximately twice the average observed in normal individuals. The number was usually within the normal range both during and after recovery from cardiac decompensation; the average numbers, however, were greater approximately 9 and 3 times respectively than in normal individuals, the average being less in patients without heart failure than in those who had recently recovered from it and less than in those who were still suffering.—*Authors' summary.*

7355. **STIMSON, CHENEY M., and HAROLD W. JONES. The erythrocyte sedimentation test in gynecology.** *Amer. Jour. Obstetr. & Gynecol.* 17(7): 81-93. 1 fig. 1929.—Following a concise review of the literature the authors give their observations. They used the Cutler method as it shows not only the distance of settling in a given time but also, the equally important, manner of sedimentation (in 4 types). In early abortion, the frequent acceleration of sedimentation and temperature elevation with associated sapremia made the determination of definite infection questionable unless there was leucocytosis also. In pelvic inflammatory disease "sedimentation will indicate the exact time when operation may be undertaken with the minimum of risk," the temperature and leucocyte count to the contrary in some instances. The incidence of complications was indicated by the test in cases of myoma, pelvic relaxation and displacement, and ovarian cyst. Sedimentation in cancer was increased in all but early, superficial growths,—"the further advanced the malignant process, the more marked the sedimentation reaction." Unruptured and early ruptured ectopic pregnancies with slight hemorrhage showed little disturbance of sedimentation; whereas, those with marked bleeding and those with rupture for several days gave marked reactions. Uncomplicated cervicitis gave practically normal sedimentation. The reaction in urological conditions depended upon the extent of the inflammatory process. Attention is called to the fact that lesions in the body distant from the one in question can cause an increased sedimentation rate.—*R. S. Siddall.*

7356. **TAKATA, M., and I. SUZUE. On the relation of physical constitution to tumors of uterus, with special reference to uterine cancer and myoma.** *Japanese Jour. Obstetr. and Gynecol.* 11(1): 51-53. 1928.—Studies were made of 278 patients: 81 cases of carcinoma uteri, 35 cases of myoma uteri, 33 cases of ovarial cyst, 5 cases of papilloma ovarii, 1 case of sarcoma uteri, 3 cases of chorioepithelioma, the rest controls. The following conclusions were drawn: 1) Patients having carcinoma uteri were of strong constitution. 2) Myoma uteri was found in general among women of moderate or relatively weak constitution: adenomyoma uteri (6 cases) appeared among women of more or less strong constitution. 3) Ovarial cyst appears more likely to occur in women of strong constitution. The authors believe there are 2 sorts of ovarial cyst; 1, the simple retention cyst and the other, the genuine tumor. 4) Papilloma ovarii appeared among women of strong constitution. 5) Chorioepithelioma appeared (3 cases) among women of rather weak constitution, but cannot be definitely affirmed as the number of cases examined was so small. 6) Cancer of vagina or ovary appears more likely among women of strong constitution.

7357. **TAYLOR, HOWARD C., Jr. The etiology of neoplasms of the breast, with notes on their relation to other tumors of the reproductive system.** *Arch. Surg.*

21(3): 412-443. 4 fig.; (4): 597-665. 1930.—Taylor's is a more individualized study than Janet Lane-Claypon's massive report on 508 cancer cases and as many controls. He prefaces his study by observing that: It is the ovarian secretion to which the breast cell is specifically responsive throughout life. In many respects a normal response of the parenchyma of the breast to the ovarian secretion differs only slightly from that of certain neoplastic processes. As illustrated by the work of Eugen Albrecht, tumors resemble organs in structure, behavior, and probably origin. Tumors of other parenchymatous organs of the reproductive system have in many cases been shown to be caused by ovarian dysfunction, which, according to evidence now given, also probably causes certain borderline hypertrophies and hyperplasias between physiologic and neoplastic growths. Experimental evidence is cited concerning mammary cancers in animals. It may be highly significant, Taylor suggests, that in mice, tumors, strongly hereditary and affected by oophorectomy, are glandular cancers as in women, while attempts to produce mammary cancers in rabbits by a local irritant resulted only in epithelioma. The parenchyma of the breast has been shown to depend on the sexual cycle for all its normal variations of structure and to be capable of rapid growth and transformations under certain physiologic conditions of ovarian activity. In this respect the breast is similar to the endometrium, the thyroid and certain ovarian structures. Pathologically, the various forms of tumor of the breast have their counterparts in the tumors of the 3 organs mentioned and of the prostate. What clinical observations can be collected from the literature and from this study of 271 cases indicate that etiologically the tumors of the breast, including carcinoma, are closely related to those of the endometrium, thyroid and ovary, are somewhat allied to myomas of the uterus and are in a way equivalent to tumors of the prostate. The tumors of these 5 organs, therefore, form a group, the etiology of whose members shows many points of resemblance. To attempt to relate inflammatory accidents of lactation to cancer of the breast is to classify it etiologically with cancer of the cervix, which on both inductive and deductive grounds appears unjustifiable. It is possible that the contrast afforded by the causes of these 2 common types of new growth may lead to the formulation of a general principle. Such a principle would amend the teaching that cancer results from chronic irritation by adding that the stimulus must as a rule be of the same type as that to which the particular tissue is biologically best adapted to respond with poliferation. Such a conception would appear, superficially at least, to reconcile the conflicting theories of numerous authors, who have formed their opinions of the causes of cancer from the study of the new growths of entirely different tissues. With this view it would be entirely consistent for mechanical or chemical irritants to produce cancerous changes in the protective epithelial cells covering the surface of the body and lining the walls of the intestinal tract, for an infectious agent to induce new growth in lymphoid, myeloid or granulomatous tissue, for trauma to produce tumors by evoking the reparative function of fascial and osteogenic cells and finally for hormonal influences to be effective in producing hypertrophy, hyperplasia and neoplasms in the breast and other organs whose normal growth processes are under endocrine control.

7358. **THOMPSON, A. RALPH. Renal and ureteric stone formation.** *Guy's Hosp. Rept.* 79(2): 173-200. 1929.—Post-mortem records at Guy's Hospital from 1890 to 1909, at the London Hospital for 1909 and 1910, and the Victoria Hospital for Children from 1889 to 1912, totalling 12,888, were read, and among them 2200 cases were found with some urinary interest. Stone, defined as any collection of precipitated mineral matter in the urine, was found in 162 instances, about equally divided between the sexes, more often on the right, and bilateral in ⅓ of the total. Bright's disease is sometimes diagnosed when a stone is present, and may be caused by the stone, occurring more often in males. Bilateral pyonephrosis is more common in females. Stone may form in the urinary tract as the result of some wasting disease. Stone more commonly forms in the kidney pelvis. Compensatory hypertrophy of one kidney, when the other is diseased, is not common. Stones may recur after operative removal. Three tumors were recorded in which stone appeared important as a cause. The travelling stone is serious, especially if it becomes impacted. Local spread of disease of the kidney following on the presence of a stone is very rare.—*B. C. Russum.*

7359. **VOLTERRA, M. Ricerche sperimentali della patogenesi delle leucemie. Riproduzione del quadro leucemieo negli animali con iniezione di ultrafiltrato del sangue leucemico. [Reproduction of the leucemia picture in animals following injection of an ultrafiltrate of leucemic blood.]** *Lo Sperimentale* 84(4): lxx-lxxiii. 1930.—Ultra-filtrates of blood of individuals with myeloid leucemia reproduced a transitory picture of leucemia when injected into white mice or guinea pigs. It is postulated that cause of leucemia is of chemical nature. —*M. L. Menten.*

7360. **WAKEMAN, A. MAURICE, and CLARENCE A. MORRELL. Chemistry and metabolism in experimental yellow fever in Macacus rhesus monkeys. I. Concentration of nonprotein nitrogenous constituents in the blood. II. Nitrogen metabolism.** *Arch. Internal Med.* 46(2): 290-305; (3): 382-401. 1930.—I. Determination of total nonprotein N and the individual nonprotein nitrogenous components (urea, amino-acid, ammonia, uric acid and creatinine) have been made on the blood of [31] normal *Macacus rhesus* monkeys and similar animals with experimentally produced yellow fever. Uric acid, creatinine, rest N and ammonia are not constantly altered, although creatinine and rest N usually rise to a variable extent in the terminal stages of the disease. The constituents chiefly affected are urea and amino-acids. Amino-acid N rises rapidly in the terminal stages of the disease; urea N may rise, but sometimes remains constant or falls. In any case amino-acid increases proportionately far more and urea far less than total nonprotein N, evidence that the power of the liver to deaminize amino-acids and to produce urea is greatly impaired or destroyed. This functional derangement becomes apparent only during the last hrs. of life.—II. Studies of changes in the nonprotein nitrogenous substances in the blood and urine of [5] *rhesus* monkeys suffering from yellow fever are presented. The nonprotein N, amino-acid, urea and rest N of the blood, increase by considerable amounts during the last hrs. of life. Blood creatinine, uric acid and ammonia change little if at all. Amino-acid increases both in absolute amount and in proportion to the nonprotein N, while urea decreases in proportion to nonprotein N. A few cases were found in which there was an absolute decrease in blood urea N. These changes were found to be terminal events. No significant alterations occurred during the early stages of the disease or in monkeys which recovered. There were no marked alterations in the partition of these substances in the urine. The changes in the terminal period are much more pronounced when the accumulation of these substances in the body fluids is considered. Organic acid and P excretion usually increased considerably during the disease. The changes observed were interpreted as resulting from a loss of liver function. No definite evidence of serious impairment of kidney function was observed, except a terminal anuria probably due to extreme reduction of blood pressure.—*Authors' summaries.*

7361. **WIECHMANN, ERNST. Hypertension und Blutzucker.** *Arch. Klin. Med.* 161(1/2): 92-110. 1928.—The author investigated the question as to whether hypertension is more frequent in diabetics than in similar aged individuals with normal metabolism and the blood sugar factor in hypertension compared to that in diabetics. He concludes that there is a close relation between hypertension and diabetes mellitus, that hyper-

tension is more frequent in diabetics than in non diabetics, that the blood sugar condition in hypertension is characteristically like that in diabetics. Hypertensives exhibit the same partition of sugar between plasma and erythrocytes as diabetics. The blood sugar difference of venous and arterial plasma in the morning without breakfast is as a rule less in hypertensives than in normals, while in the main this difference was not found marked. It was, however, more pronounced when glucose was administered. A latent diabetes exists in a majority of hypertensives.—*W. F. Jacobs.*

7362. **WILLIAMSON, RAYMOND. Observations on the pulmonary ventilation and oxygen consumption in pulmonary tuberculosis, and on the effect of the respiratory quotient on the relation between pulmonary ventilation and oxygen consumption.** *Quart. Jour. Med.* 21(83): 371-382. 10 fig. 1928.—O consumption and pulmonary ventilation in patients with pulmonary tuberculosis when examined over a considerable period under basal conditions vary together; the results of the experiments when plotted out graphically give a curve approximating to a straight line. Even under varying conditions there is an approximately direct relationship between the O consumption and pulmonary ventilation. Experiments on a normal subject show that there is a relationship between O consumption and pulmonary ventilation which is close under basal conditions, but not so close under other conditions, being considerably modified by the respiratory quotient. The results of the experiments when plotted out show that the points do not fall on a straight line, but within a narrow band, their position in the band depending on the respiratory quotient. For practical purposes the relationship between O consumption and pulmonary ventilation seems sufficiently close to permit the assumption that the measure of pulmonary ventilation indicates the rate of metabolism. It is suggested that in pulmonary tuberculosis measurements of the pulmonary ventilation at intervals under similar conditions may be a useful method of investigating the progress of the patient. For the same amount of work a greater pulmonary ventilation is required by a tuberculous subject than by a normal one, and in consequence dyspnea will ensue earlier in the tuberculous subject.—*Author's summary.*

7363. **YOSHIDA, YONETARO. Malignant tumours and blood catalase.** [In Japanese.] *Jour. Gastroenterol.* 1(8): 791. 1926.—In experimental malignant tumors in hens, rabbits, and albino rats, blood catalase (by *Inoue-Ochi-Shirai's* method) and hemoglobin were estimated. The ratio obtained is called the hemoglobin-catalase index. The index shows a marked difference according to the kind of animals. The individual difference is most marked in hens and rabbits and relatively small in albino rats. In the same individual the daily difference is very small. Hen myoma, rabbit myoma, albino rat myoma, and albino rat carcinoma were transplanted in the experimental animals; the blood catalase decreased gradually with the lapse of time after the transplantation. The degree of the decrease was most marked in the case of hen myoma, then in rabbit myoma, least marked in albino rat myoma and albino rat carcinoma. As in all the cases the hemoglobin-catalase-index rather decreases with the growth of the tumor, the decrease of the blood catalase is not due merely to anemia.—*Courtesy Jap. Jour. Gastroenterol.*

7364. **ANTHONY, D. J., F. W. JACKSON, and T. G. JOYCE. "Black gut."** *Vet. Rec.* 11(31): 801-803. 1931.—A black discoloration sometimes found in the caecum and colon of pigs is shown to consist of ferrous sulphide. Specimens of the caecum in which the discoloration is present possess pH values over 6.5; normal specimens show lower values. The view is advanced that ionic Fe in process of excretion emerges through the intestinal wall into a neutral or alkaline medium containing soluble sulphide, with resulting precipitation in situ. Occurrence or non-occurrence of the deposit thus depends on variations in the reaction of the large intestine. These variations may arise through diverse methods of feeding or differences in intestinal flora. The importance of the discoloration commercially and in post-mortem work is mentioned.—*D. J. Anthony.*

Vet.* 12(5): 35-40. 1931.—A résumé of the results of studies by American investigators, of diseases involving the upper respiratory tract of fowls including fowl-pox and avian diphtheria, coryza, vitamin A deficiency, and infectious laryngotracheitis. A bibliography of 32 references is appended.—*J. R. Beach.*

7366. **BECKER, R. B., W. M. NEAL, and A. L. SHEALY. I. Salt sick: its cause and prevention. II. Mineral supplements for cattle.** *Florida Agric. Exp. Sta. Bull.* 231. 5-23. 1931.—I. "Salt sick" of cattle on certain iron-deficient sandy and residual soils has proved to be a nutritional anemia due to deficiency of Fe, or of Fe and Cu in the forage crops. Symptoms are progressive loss of appetite, emaciation, retarded growth, low hemoglobin content and diminished blood volume. The spleen parenchyma is atrophied, the heart muscle lacks tonus, and the tissues are pale. Cattle of all ages, as well as sheep, goats and swine, are affected. Animals recover when changed to clay range areas, or when the deficient minerals are supplied. II. There is a popular discussion of the following mineral supplements for cattle: NaCl, Ca, P, I and S. The Ca, P and Fe contents of some local forages are presented; also salt and bonemeal consumption by cattle.—*R. B. Becker.*

7367. **BENESCH, F., und K. STEINMETZER. Klinisch-experimentelle Untersuchungen über die normale und medikamentell beeinflusste Uterusbewegung am lebenden Rind im Involutionsstadium Puerperium.** *Wien. Tierärztl. Monatschr.* 18(3): 65-70. 2 fig. 1931.—A rubber balloon was introduced and inflated into the uterus of 5 cows, 4 hrs. to 7 days post partum, for observation to determine whether an epidural anaesthesia of the genital apparatus in the puerperium would disturb the movements of the uterus. The curves revealed the fact that the contractions of the uterus during the anaesthesia remained the same and that the anesthesia merely inhibited the voluntary pressure.—*F. Benesch (transl. by C. S. Simkins).*

7368. **BLIECK, L. de. Een haemoglobinophile bacterie als oorzaak van coryza infectiosa gallinarum. [A hemoglobinophilic bacterium as cause of coryza infectiosa gallinarum.]** [With German, English and French summaries.] *Tijdschr. Diergeneesk.* 58(6): 310-314. 1931.—The author separated coryza from fowlpox-diphtheria by infecting birds immunized against fowl-pox with antidiphtherin. He succeeded in infecting birds in series with pure coryza. No filterable virus as the cause of coryza was

found. From a case of pure coryza the author isolated a bacterium of the "influenza group." With subcultures in 8 passages, 17 fowls were infected, showing typical coryza symptoms. It was also possible to infect other birds from those originally infected by cultures. With other bacterial species cultivated from coryza cases, no experimental infections were achieved.—*Author's summary.*

7369. **BLIECK, L. de, en JAC. JANSEN. Gasoedeem bij kippen na bloedtappen. Pathogeniteit van anaërobe gasoedeembacillen voor kippen. [Pathogenicity of anaerobic gas edema bacilli for fowls.]** [With English, German, and French summaries.] *Tijdschr. Diergeneesk.* 58(16): 862-864. 1931.—3 strains of bacilli cultivated from fowls dead from malignant oedema were also found in the soil of the poultry farm and on the feathers of live fowls. After a comparative soil research, it appeared that the poultry farm was highly contaminated with anaerobic bacilli pathogenic for fowls. Of the 3 strains, the bacilli of Fraenkel and of Novy were pathogenic to fowls, but *Bacillus parasarcophysematosa* showed no pathogenicity.—*Authors' summary.*

7370. **BRAGA, AMERICO, e MOACYR ALVES de SOUZA. O cholera das gallinhas. [Chicken cholera.]** [With English summary.] *Rev. Zootech. e Vet. [Rio de Janeiro]* 17(2): 115-128. 1931.—Results of vaccination with killed cultures of *Pasteurella* as a control procedure in an outbreak of fowl cholera are discussed. As a diagnostic procedure, agglutination was tried, but with poor results. The authors point out that where fowl cholera is endemic, agglutinins for the casual organism may be demonstrated in the blood of fowls.

7371. **CAMPBELL, J. A., and P. FILDES. Tetanus. X: the effect of the oxygen tension of the tissue fluids in controlling infection by B. tetani.** *British Jour. Exp. Path.* 12: 77-81. 1931.—Experiments were done on guinea pigs the O tension of whose tissue fluids was altered by changing the composition of the air breathed, the animals being enclosed in 2 air-tight chambers and provided with sufficient water, food and bedding for 4-5 days. The chambers were fitted with pans to keep the air mixed. The CO_2 produced by the animals was absorbed by soda lime and the O used was automatically replaced. Experiments showed that the tissue O tensions of such animals could be varied in a regular manner by such measures. When the guinea pigs were inoculated with tetanus spores and aleuronate, the incidence of germination and tetanus could be reduced by increasing the O tension of the tissue fluids and facilitated by reducing it. This supports the view that the O tension of the tissue fluids controls the germination of tetanus spores.—*J. Bland.*

7372. **COTTIER, HENRI. Hygiène et médecine vétérinaire à la ferme. Encyclopédie des connaissances agricoles.** 508p. 5 pl., 168 fig. Hachette: Paris, 1929. Price 25 fr.

7373. **DALLING, T., and G. H. WARRACK. Bacillary white diarrhoea (B.W.D.).** *Eggs. (Sci. Poultry Breeders' Assoc., England)* 23(5): 79-81. 1930.

7374. **DEARSTYNE, R. S. Fundamental aspects of bacillary white diarrhea (pullorum disease).** *Proc. 21st Ann. Meet. Poultry Sci. Assoc. 1929.* [In: *Bull. Alabama Polytech. Inst.* 25(1): 77-79. 1930.]—The relative ease with which negative adult birds contract pullorum disease and develop into chronic carriers is indicated by experimental oral infection of negative birds; in about 75% the disease was established, and antibodies were demonstrated 14-18 days after infection. Studies of variations in serum titer of adult carriers indicate the possibility of temporary bacteriemias in such birds. Studies on direct transmission of pullorum disease through the egg indicate the probability of a greater ratio of infection existing than heretofore recognized.—*R. S. Dearstyne.*

7375. **DE KOCK, G. Are the lesions of jaagsiekte in sheep of the nature of a neoplasm?** *Union So. Africa Dept. Agric. 15th Ann. Rept. Dir. Vet. Serv.* 2(5/9): 611-641 15 fig. 1929.—It is concluded that there may be 2 specific lung diseases in sheep in So. Africa, viz., a chronic indurative catarrhal pneumonia, and multiple papilliform cystadenoma complicated by terminal pneumonia. Local congestion of the alveolar capillaries as a stage in the formation of primary lesions of jaagsiekte could not be confirmed. Neither could the presence of inter-alveolar infiltration as primary lesions be substantiated in the lung sections of clinically healthy So. African sheep from known jaagsiekte-infested areas and of those still believed to be free of the disease. The early lesions of jaagsiekte consist of papilliform proliferations arising mainly from alveolar epithelium. These multiple adenomata become complicated with pneumonia from which the animal succumbs.—*F. Volkmar.*

7377. **EBER, AUGUST. Sektionsbefunde bei Legehennen, die an den Folgen gestörter Legetätigkeit gestorben sind. (Ein Beitrag zur Frage der Ursachen und des Wesens der Legestörungen beim Haushuhn.)** *Berliner Tierärztl. Wochenschr.* 46(40): 688-696. 1930.—In autopsies of hens from 1911 to 1928, the author observed soft eggs (i.e., eggs with weak shells or shell-less eggs). The defect was associated with many conditions,—deficiency of lime salts in the food; inflammation of the oviduct caused by *Prosthogonimus pellucidus* or *Plegiorchis arcuatus;* catarrhal enteritis which interfered with Ca metabolism and excited sympathetic peristalsis of the egg duct; and improper maintenance of flocks.—*H. Bunyea.*

7378. **FELDMAN, WILLIAM H. A study of the subcutaneous lesion of cattle reacting to tuberculin.** *Cornell Vet.* 21(3): 268-285. 2 pl. 1931.—An attempt was made to demonstrate the etiologic agent in subcutaneous lesions of cattle reacting to tuberculin. Most guinea pigs and rabbits used were inoculated intracerebrally. From one of the cases a *Mycobacterium tuberculosis* was isolated, which proved virulent for rabbits and chickens, but not for guinea pigs. This was considered of avian origin and may represent a chance infection. In 5 other instances, definite collections of epithelioid cells, constituting lesions resembling those of tuberculosis, were observed in the brains of 6 rabbits. Failure of the lesions to appear in the thoracic or abdominal viscera would indicate an etiologic agent of slight aggressiveness, which may or may not have been *M. tuberculosis.* The possibility of the experimental lesions being caused by dead tubercle bacilli or by strains of mycobacteria ordinarily assumed to be non-pathogenic, is considered.—*Author's summary.*

7379. **FIKENTSCHER, R. Tierische Ochronose und Porphyrie.** *Virchow's Arch. Path. Anat. u. Physiol.* 279(3): 731-739. 1931.—Presence of porphyrin in the bones was demonstrated by the fluorescent spectroscope and in histologic sections from slaughtered cattle showing ochronosis. The author failed to find it in bones of normal cattle. This refutes the suggestion that porphyrin originates from the breakdown of blood pigment during chemical examination, since primary fluorescence, spectroscopically analyzed as porphyrin, of the morphologically undemonstrable, diffusely distributed, brownish-red pigment, was obtained from bone sections which had undergone no chemical treatment. Chemical and spectrochemical examination by H. Fink showed the extracted porphyrin to be uroporphyrin. The study shows that, in at least some cases, ochronosis (osteochromatosis) of slaughtered animals is due to the presence of porphyrin. —*Author's summary (transl. by I. E. Newson).*

7380. **FRIEDRICH, Weiteres zum Problem der Sennekrankheit.** *Tierärztl. Rundschau* 37(34): 604-606. 1931.—Senna sickness of horses is not produced by molds or chemical poison as previously thought. Before the disease appears, an incubation time of 4 or more weeks is needed, indicating that it is produced by a microorganism.

7381. **GIORELLI, G. Contribution à l'étude des bactériémies post-opératoires consécutives aux extirpations des dents infectées des chiens.** *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(7/8): 355-359. 1931.—Postoperative bacteriemias in dogs are relatively rare and when they do occur are of short duration.

7382. HEIM, F. Hühnergeschwülste. *Zeitschr. Krebsforsch.* 33(1/2): 76-125. 1 fig. 1930.—This is a review of the reported literature on fowl tumors, with bibliography of about 200 references.—*H. E. Eggers.*

7384. KFOURI, PHILIPPE. Étude de la sensibilité broncho-pulmonaire du cheval à divers agents pathogènes des voies respiratoires de l'homme. *Rev. Path. Comp. et Hyg. Gén.* 31(415): 465-477. 1931.—It was shown that the Pfeiffer coccobacillus from man is non-pathogenic for lungs of horses when inoculated for the first time. Intrapulmonary re-inoculation of a large quantity of culture (80 cc.) produced a broncho-pneumonia of average intensity. This infection seemed to develop in the respiratory tract a certain degree of active immunity, protecting against 2 large inoculations (100 cc.) given later. Association of the Pfeiffer bacillus with pneumococcus Types I, II, and III, and with Friedlander's bacillus did not modify the severity of the pneumonia.—*Author's summary (transl. by M. Pittman).*

7385. KFOURI, PHILIPPE. Recherches sur la sensibilité bronchopulmonaire du cheval aux pneumocoques type I, type II, type III, d'origine humaine. *Rev. Path. Comp. et Hyg. Gén.* 31(416): 545-559. 1931.—The first inoculation of pneumococci into the lungs of young horses is followed by a severe lobar pneumonia which heals spontaneously in about 8 days. After convalescence, injection of virulent pneumococci fails to produce infection, but the horse reacts with mild pulmonary congestion. No immunity results unless the first injection is followed by at least a subacute, temporary broncho-pneumonia. These experiments demonstrate that development of active immunity in lungs of horses depends on the development of the pneumonia.—*Author's conclusions (transl. by L. C. Havens).*

7386. KIESSIG, W. Zur Diagnose der Streptokokken-Mastitis. *Deutsche Tierärztl. Wochenschr.* 39(36): 570-571. 3 fig. 1931.—Cultural diagnosis is discussed.

7387. KLARIN, E. Undersökning över förekomst av B. abortus Bang i mjölk från kor, som kastat till följd av infektion med denna bakterie. [Bacillus abortus Bang in milk from aborting cows.] *Skandinavisk Vet.-Tidskr.* 21(8): 249-269. 1931.—Cows which have aborted from infection with *B. abortus* frequently show the organism in the milk, usually from the 1st week after abortion. Milk infection is probably due to autogenous infection from the uterus. Occurrence of the bacteria in the milk usually lasts 2 mo. or more, but may cease after 2-4 wks. If milk infection first appears 6-8 weeks after abortion, it is probable that infection of the cow has come from external sources. In affected herds, cows may secrete *B. abortus* with their milk, whether or not they have aborted.—*From author's English summary.*

7388. LACHENSCHMID, B. Ueber den Keimgehalt der Gallen gesunder Schlachtkälber. *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39(1/2): 94-101. 1931.—Examination of the bile of 550 healthy calves failed to reveal paratyphoid infection,—contrary to the prevailing opinion that healthy calves occasionally harbor organisms of this group.—*L. D. Bushnell.*

7389. LUND, L. Grundriss der pathologischen Histologie der Haustiere. [Elements of pathological histology of domestic animals.] xii+471p. 311 fig. M. & H. Schaper: Hannover, 1931.

7390. MEYER, J. R. Observações anatomo e histopathologicas feitas em orgãos de papagaios (Amazona amazonica e A. farinosa) mortos espontaneamente e após inoculação de um virus que se demonstrou filtravel. [Anatomical and histopathological observations on organs of parrots (A. amazonica and A. farinosa) dying spontaneously and when inoculated with a filterable virus.] *Arch. Inst. Biol. Defesa Agric. e Animal* 4: 25-38. 8 pl. (5 col.) 1931.—The research is based on 30 parrots—2 normal, 16 spontaneously infected with a disease similar to avian psittacosis, and 12 after inoculation with material from the diseased birds. The macroscopical lesions encountered in the psittacosis-like disease consisted in a general congestion, accumulations of a clear fluid in the serous cavities, and in a large number of whitish, yellow or grayish areas in liver and spleen. The main microscopical lesions were found in the liver and spleen. The acute processes were represented by focal necrosis and the presence of large, semilunar-shaped inclusions in the nuclei of both liver and splenic cells. The lesions of the chronic type consisted in proliferation of mesenchymatous cells around the small vessels of the liver or in proliferation of reticular cells in the splenic pulp. In several cases there was found, around the focal necrosis, a cytoplasmic mass containing numbers of nuclei. In other cases, leucocytes were found in the bile ducts.

7391. MIAOULIS, V. Coexistence du charbon bactéridien et de la babésiellose ovine. *Rec. Méd. Vét. École d'Alfort* 107(8): 463-464. 1931.—Autopsies and microscopical examinations of sheep in Greece, showing coexistence of anthrax and babesiellosis in sheep.

7392. PACHECO, GENESIO, e OTTO BIER. Epizootia em papagaios no Brasil e suas relações com a psittacose. [Parrot epizootic in Brazil, resembling psittacosis.] *Arch. Inst. Biol. Defesa Agric. e Animal.* 4: 89-120. 1 pl. 1931.—An epizootic was observed among parrots in an aviary in a Park in São Paulo. Clinical and post-mortem symptoms were similar to those of psittacosis; the organisms isolated were Salmonellas, but distinct from Nocard's *S. psittacosis*, which was isolated from 3 other cases. Attempts to transmit the disease were unsuccessful. From 2 parrots bought in a store a filterable virus was obtained, which could be transferred indefinitely to other parrots without alteration of pathogenic properties, but which was non-pathogenic to laboratory animals (guinea pigs, white mice, chicks, pigeons and monkeys). The reservoir of human psittacosis in Europe is attributed to *Amazona aestiva*, not *A. amazonica* [Psittacidae].

7393. PETERSEN, WILLIAM E., E. A. HEWITT, W. L. BOYD, and W. R. BROWN. Artificially induced hypoglycemia in the cow and the relationship to parturient paresis or milk fever. *Jour. Amer. Vet. Med. Assoc.* 32(2): 217-227. 1931.—Hypoglycemia: The bovine tolerates a much lower blood-sugar level than is reported for other species. The rather prolonged cases of hypoglycemia, going as low as 17 mg. per 100 cc., show that low blood sugar is not a cause of parturient paresis. Hypocalcemia: Beef animals gave some evidence of tetany, while only 1 of the dairy animals showed symptoms that could be likened to tetany. If only sufficient sodium citrate is injected to cause a marked staggering gait, spontaneous recovery follows promptly. $CaCl_2$ in 20% solution must be given intravenously. If not carefully administered, varying amounts of the solution will be deposited in the tissues, which may result in edema, abscesses, necrosis and Phlebitis.

7394. PROSCHOLDT, O. Gärtnerinfektionen der Kälber und Rinder. *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39(1/2): 115-140. 1931.—The author discusses numerous outbreaks of Gärtner bacillus infection in calves and cows. In all, he studied 505 strains of the Gärtner-paratyphoid group. Of these, 404 were Gärtner-enteritidis, 61 Breslau-enteritidis, 2 Schottmüller type, 1 *B. paratyphosus abortus equi*, and 37 undetermined strains. He considers a positive agglutination test in calves at dilutions of 1:100 as diagnostic of infection, although titers of 1:400 or higher are reported. In adult cows which become carriers, titers of 1:12,000 are reported. It is recommended that bacteriological examinations be made of the feces and blood of suspected animals to detect carriers.—*L. D. Bushnell.*

7395. REIS, JOSÉ, e ANNITA SWENSSON. Flora estreptococcica das mammites esporadicas. I. Revisão geral do assumpto e contribuições originaes para seu conhecimento no Brasil. [Streptococcic flora of infectious mastitis of cattle. General review and original contributions toward the knowledge of the subject in Brazil.] *Arch. Inst. Biol. Defesa Agric. e Animal* 4: 143-190. 2 pl.

1931.—The authors can not accept the use of media of lowered surface tension for differentiation of streptococci from sour milk and from mastitis, and show the absence of uniformity in results obtained by use of different techniques. From a study of 54 strains of streptococci, they conclude that assumption of specificity for mammitis streptococci is erroneous. *Streptococcus mastiditis* is critically studied. The conditions under which successful experimental production of mammitis in cows and goats may be accomplished are described. A bibliography of 7p. is appended.

7396. **REIS, JOSÉ. Estudos sobre cholera aviaria. I. Diagnostico de cholera em cadaveres em putrefacção. [Studies on avian cholera. 1. Diagnosis of cholera in putrefying cadavers.]** *Arch. Inst. Biol. Defesa Agric. e Animal* 4: 291-300. 1931.—In carcasses decomposed in the air, diagnosis of avian cholera by inoculation in a rabbit was successful 11 days after death; this was also possible in an exhumed bird, but search must also be made for *Pasteurella* in smears from decomposed organs. In 12-day carcasses determination was impossible.

7397. **RYDIN, KARL. Något om sjukdomar hos våra pälsdjur. [Diseases of our fur-bearing animals.]** *Svensk. Veterinartidskr.* 35(7): 199-204. 1930.—The author calls attention to the similarities of the maladies of dogs kept in kennels, to those encountered in foxes, martins and minks kept for fur-bearing purposes. A number of the now common ailments are discussed. —*B. Bickel.*

7398. **SIGWART, H.** Lamsiekte of sheep in South West Africa. *Jour. So. African Vet. Med. Assoc.* 1(3): 25-29. 1 fig. 1929.—The first cases occur during August and the losses increase as progressing drought reaches its culminating point in December or January. The majority of sheep affected are ♀♀. The disease is associated with depraved appetite. Symptoms and pathological lesions resemble those in cattle, but the course is more acute. *Clostridium parabotuinum* could not be found in blood smears. Feeding of bone meal prevented the disease.—*F. Volkmar.*

7399. **SMITH, DAVID T., NORMAN BETHUNE, and J. L. WILSON. Etiology of spontaneous pulmonary disease in the albino rat.** *Jour. Bact.* 20(5): 361-370. 1930. —An unidentified anaerobic coccus and an aerobic bacillus were isolated from the lungs of albino rats with spontaneous pulmonary disease. A symbiosis of the 2 organisms was demonstrated by failure to reproduce the disease from inoculation of pure cultures of either, while the combined pure cultures produced a lesion identical with the spontaneous disease. In the use of albino rats for experiments on pulmonary tuberculosis, care should be taken to exclude a spontaneous lung disease.—*J. B. Nelson.*

7400. **SOITUZ, V. Sur un staphylocoque adapté à la glande mammaire de la lapine.** *Rev. Path. Comp. et Hyg. Gén.* 30(392/393): 381-388. 1930.—Staphylococci found in the mammary gland of a lactating rabbit were thought to have been perhaps the result of a generalized infection, since Calmette and Petit have demonstrated that virulent staphylococci are capable of traversing the intestinal mucosa and eventually producing generalized infection.—*Author's summary (transl. by C. S. Gibbs).*

7401. **THOMSEN, AXEL. L'avortement épizootique à Brucella chez les porcs au Danemark.** *Rev. Gén. Méd. Vét.* 40(476): 457-466. 1 fig., 1 map. 1931.—This disease spread to 150 herds in central Jutland and was carried to Seeland by infected animals sold there. Spread is often brought about by the wind, but also by mating with an infected boar. The genitalia of 6 infected boars were examined and the organism was isolated from 6, especially in the seminal vesicle. All the stock cultures (22) grew aerobically in the 1st generation. Transmission from hogs to cows and vice versa was not demonstrated. Examination of 5,600 sows and boars from Danish abattoirs shows that the malady was limited to this outbreak.—*Author's summary (transl.).*

7402. **TRUCHE, C., et J. BAUCHE. Contribution à l'étude de la pseudo-tuberculose des oiseaux.** *Bull. Acad. Vét. France* 3(9): 391-394. 1930.—An account of pseudotuberculosis avium in the canary (*Passer canaria*) and duck (*Anas domestica*), due in both cases to the bacillus of Mallasez and Vignal.—*R. C. Whitman.*

7403. **VERSÉ, M. Bemerkungen zur Frage der Cholesterinkrankheit des Kaninchens.** *Beitr. Path. Anat. u. Allg. Path.* 80(1): 235-238. 1928.—Rabbits (24) were fed 0.7-340 gm. cholesterol and 14-2636 cc. oil as pure cholesterol, pure linseed oil, or cholesterol plus linseed or peanut oil, and observed for 1-650 days. The initial liver wt. was about 3 gm. per 100 gm.; the final, 55-250 gm.; the livers were markedly fatty. Rabbits fed pure cholesterol showed small, brown, cirrhotic livers with but little fatty degeneration. In cholesterol-oil feeding, the fat appeared predominantly in the central and middle zones of the lobules and, as in feeding pure linseed oil, fat drops were found in the epithelium of the small biliary ducts, rarely in the medium, and never in the large ducts. In animals receiving pure cholesterol, there was but little fat in the small biliary ducts but more fatty infiltration in the star cells. Normal feeding of cholesterol: oil in the proportion of 0.025: 0.5 gm. per 100 gm. animal per day and dose must be instituted to obtain values with which other experimental work may be compared.

7404. **WALL, SVEN. Nötkreaturstuberkulosnes utbredning i Sverige länsvis under åren 1918-1929 jämförd med människotuberkulosens utbredning i riket under åren 1911-1929. [Spread of tuberculosis in cattle in Sweden, according to Government districts, 1918-1929, compared with that of tuberculosis in man, 1911-1929.]** [With English summary.] *Skandinavisk Vet.-Tidskr.* 21(5): 121-173. 4 fig. 1931. —Investigation of tuberculosis in cattle shows with certainty that it is on the increase in most of the government districts of Sweden. The occurrence is now highest in the provinces lying around Lake Mälar, then follow the Scanian and Västgöta provinces, and the government districts of Halland and Kalmar. Lower % occur in the provinces of Göteborg and Bohus, Jönköping, Kronoberg, Blekinge and Västernorrland. The districts of Gotland, Västerbotten and Jämtland are relatively free. Investigation of the extent of tuberculosis in man shows it is diminishing in all the provinces. At present the number of deaths per thousand population is highest in the province of Norrbotten, followed by the districts of Västerbotten, Jämtland, Västernorrland, Gävleborg, Blekinge, Göteborg, Bohus, Gotland, Kopparberg, Värmland and Stockholm. A relatively low mortality is displayed by the districts of Kahmar, Kronoberg, Uppsala, Västmanland, Halland, Örebro, Älvsborgs, Jönköping, Skaraborg and Kristianstad, lowest mortality returns being found in the provinces of Malmöhus, Östergötland and Södermanland. Bovine and human tuberculosis spread throughout Sweden independently of each other. A more detailed investigation of mortality from tuberculosis in children up to 5 yrs. of age seems to point to infantile tuberculosis as having 2 sources of infection, viz., man, and cows with tuberculosis of the udder.—*From author's summary.*

7405. **WOLTERS. Über das Vorkommen von Geflügeltuberkelbakterien beim Rind.** *Deutsche Tierärztl. Wochenschr.* 39(35): 548-550. 1931.—By cultural methods, acid-fast bacilli were obtained from milk samples. Differentiation and culture in solid and liquid malachite green media and animal inoculations showed them to be avian tubercle bacilli. Tests from individual cows showed that the milk of some contained the avian bacillus. Such infections occurred on small farms. In 80 samples of bovine sputum, avian tubercle bacilli were found 4 times.—*Author's summary (transl.).*

7406. ADAMSKI, J. Sur la valeur biologique des lipoïdes isolés des antigènes, dans la réaction de Bordet-Wassermann, après fractionement par l'eau salée. *Compt. Rend. Soc. Biol.* 106(10): 857-858. 1931.—It is possible to obtain by fractionation of a great number of antigens, even the less active ones, lipoids from the sediment, the action of which in the Bordet-Wassermann reaction (in more than 2000 cases) is very close to that of secondary lecithin described by Kiss, as well as to that of standard antigens. It is necessary to determine their concentration, since, in the technique described, it does not pass 1 mgm. of lipoid for 4 mgm. of cholesterin in alcoholic solution in 14 cc. of saline.

7407. ALSTON, J. M., and D. STEWART. Some observations on passive immunity in the normal subject produced by antipneumococcic sera. *British Jour. Exp. Path.* 12: 49-56. 1931.—Normal healthy persons were given intravenous injections of different antipneumococcal sera, and at varying intervals after injection their blood was tested for bactericidal effect on types I, II, and III pneumococci, and their serum for power of protecting mice against lethal doses of the 3 types. The antipneumococcal sera used contained antibodies against types I and II but not against III. The bactericidal power of the blood and the protective action of the serum may be greatly increased for at least 72 hrs. as regards type I and II pneumococci, by such injections in therapeutic doses. The validity of the results was checked by the lack of change in bactericidal power of blood against type III organisms, and by the smaller or negligible increase in bactericidal power or protective action when the injection given was a fraction of a therapeutic dose of other preparations of immune serum.—*J. Bland.*

7408. ANTON, HELLMUT. Zur Frage nach dem Vorhandensein einer Beziehung zwischen Giftresistenz und Fettgehalt weisser Mäuse. *Arch. Hyg. u. Bakt.* 105 (5): 275-286. 1931.—After they had attained uniform wt., food was withheld from 56 mice for 16 hrs., 0.014-0.02 cc. 50% alcohol per gm. wt. (lethal dose, 0.02 cc. 50% alcohol per gm. wt.) was given with a sound, then food; 24 died; those not dying in 48 hrs. were killed, and fat was extracted; it varied from 4 to 25%. No relation between resistance to alcohol and fat content was found. After 70 ♂ mice were brought to uniform wt., they were divided into 2 groups, one fed abundantly (F) the other (M) very little (6 died). After 4 weeks, both groups were fed moderately for 2 days; group F averaged −8.6% and group M +1.5% of initial wt., though there were pronounced deviations. After injection the lethal dose (0.0125 cc. per gm. body wt.) of tetanus toxin (1: 100,000), 66⅔% of group F and 13⅓% of M died within 14 days. Relative to wt. before division into groups, however, animals which had lost most wt. showed lowest mortality; in group F there was lower mortality in those weighing least. Another group of 163 mice, after attaining uniform wt., were given 0.014 cc. of 1: 100,000 tetanus toxin per gm. wt.; here again, the lighter mice were more resistent than the heavier; of animals of the same wt., there appeared to be a higher mortality among the pronouncedly longer ones (tip of nose to root of tail).

7409. AREA LEAO, A. E. de. L'intradermo-réaction dans l'actinomycose. Réaction spécifique de la peau avec le filtrat de culture d'Actinomyces bovis. *Compt. Rend. Soc. Biol.* 98(17): 1575-1576. 1928.—Individuals with actinomycosis gave a local reaction (pain, oedema, rise in temp.); healthy controls did not. Use of inoculation in diagnosis of cases of internal actinomycosis is suggested.

7410. ARTHUS, MAURICE. Les anavenins (quatrième mémoire): I. Toxicité des sérums formolés pour les animaux anaphylactisés. 2. Réactions d'anaphylaxie provoquées par les anavenins. *Jour. Physiol. et Path. Gén.* 29(2): 256-269. 1931.—It is not possible by treating horse serum or ovalbumin with formaldehyde to render them harmless to anaphylactically sensitized rabbits. Anavenins, freed from formaldehyde, are able to evoke an anaphylactic response in rabbits previously sensitized to the anavenin, the corresponding snake venom, or even to other avenins or proteins.—*W. R. Fearon.*

7411. ASSIS, ARLINDO de. Sobre a vaccinação antituberculosa pelo BCG por via subcutanea. (Ensaios no Preventorio Dona Amelia.) [Subcutaneous vaccination of children with BCG in the "Preventorium Dona Amelia."] *Brasil Medico* 45(5): 97-103. 1931.—The paper deals with the subcutaneous use of BCG in 25 healthy children living permanently in a "preventorium" free from tuberculous contact. After testing each child several times intradermally with large tuberculin doses (1 mg.), only those with permanent − reaction to tuberculin were chosen for BCG vaccination. Doses of 0.01-0.1 mgm. of living BCG proved quite harmless, a marked local reaction being noticed in one case of cold abscess that healed completely after evacuation. A slight degree of tuberculin allergy was constantly found as the result of BCG inoculations, whenever the doses reached 0.06-0.1 mgm. of BCG. Large intradermal doses of tuberculin, as well as early readings of results (24 hrs.), are to be strictly observed to secure clear-cut results. Subcutaneous reinoculations of BCG in children whose tuberculin allergy had ceased, proved also to be innocuous, and carried out again the state of tuberculin hypersensibility that seemed to be somewhat more decided than after the 1st injection. Additional notes on variations of tuberculin allergy in apparently healthy children follow.—*A. de Assis.*

7412. BAILEY, G. HOWARD, and MARY SHAW SHORB. Heterophile antigen in pneumococci. *Amer. Jour. Hyg.* 13(3): 831-856. 1931.—An antigen corresponding in properties to the heterophile component of sheep erythrocytes is present in the various types of pneumococci and in certain strains of green-producing streptococci. Pneumococci stimulate production of the Forssman anti-sheep hemolysin in high titer when injected intravenously into rabbits, and after boiling absorb the hemolysin so produced when mixed with it in vitro; while the hemolysin itself has all the characteristics of the heterophile type, including primary toxicity for guinea pigs. There is an indication that heterophile antigen and antibody have a biological significance in pneumococcus infections, since immunization of rabbits with sheep erythrocytes renders them relatively resistant to pneumococcus infection.—*G. H. Bailey.*

7413. BARR, MOLLIE, and A. T. GLENNY. The preparation of fractions of different antitoxic quality from the same serum. *Jour. Path. and Bact.* 34(4): 539-543. 1931.—A diphtheria antitoxic plasma yielded, by successive precipitations with solid $(NH_4)_2SO_4$, a series of globulin fractions of different antitoxic quality as measured by the in vivo/in vitro ratio. The ratio of the fractions precipitated by the least quantities of $(NH_4)_2SO_4$ exceeded that of the original plasma (1.52) and a progressive decrease was obtained throughout the series, from 2.69 in the first fraction to 0.93 in the

last. The results suggest the existence, in the same serum, of different types of antitoxin qualitatively distinct.—*A. T. Glenny.*

7414. **BELEZKI, W. K., und R. M. UMANSKAJA. Über die Natur der Immunität bei Rückfallfieber. VII. Morphologische Untersuchung der Schutzfunktionen bei Rückfallfieber des Menschen.** *Virchow's Arch. Path. Anat. u. Physiol.* 272(2): 305-312. 5 fig. 1929.—Spirochaetolysins play an important rôle in combating the infection, lysis occurring both in blood stream and in organs. Phagocytosis was very active in the tissues and less so in the blood. Phagocytosis occurs in the reticulo-endothelial cells of the organs, the migratory and fixed histiocytes, and in the monocytes of histiocytic origin. In the central nervous system, the glia cells function as phagocytes.—*J. T. Myers.*

7418. **BOXWELL, W., and JOSEPH W. BIGGER. Autohaemagglutination.** *Jour. Path. and Bact.* 34(4): 407-417. 1931.—A case of autohemagglutination in a female, aged 65, suffering from anemia and an atypical leukemia, is described. The literature is reviewed and it is concluded that up to the present only 22 authentic cases of autohemagglutination have been described. The following definition is propounded: "Autohaemagglutination is a clumping of erythrocytes into irregular masses, visible to the naked eye, occurring in the presence of the individual's own serum, without bacterial action, at air temperature and reversible at body temperature."—*J. W. Bigger.*

7419. **BROWN, AARON, E. L. MILFORD, and A. F. COCA. Studies in contact dermatitis. I. The nature and etiology of pollen dermatitis. Preliminary report.** *Jour. Immunol.* 20(5): 393. 1931.

7420. **BURNET, F. M. The interactions of staphylococcus toxin, anatoxin and antitoxin.** *Jour. Path. and Bact.* 34(4): 471-472. 1931.—Toxin detoxicated with formalin is an effective antigen; its binding power is ½ that of the toxin from which it was derived. The theory of toxin-antitoxin combinations is discussed.—*A. E. Boycott.*

7421. **CAPUA, F. de. Sulla trasmissibilità di anticorpi per via placentare.** *Pediatria Rivista* 36(4): 186-195. 1928.—Studies on the rabbits prove that while hemagglutinins do not pass the placenta, hemolysins are thus transmitted, but not all rabbits born from the same delivery have the same quantity of hemolysins. The rapid disappearance of the hemolytic power of the serum after the birth suggests that it is due to a passive immunity.—*E. Ponzi.*

7422. **CARPENTER, C. M., RUTH BOAK, and O. D. CHAPMAN. The significance of Brucella abortus agglutinins in human serum.** *Rept. New York State Vet. Coll. Cornell Univ.* 1928/1929: 111-125. 3 fig. 1930.—Agglutination tests for evidence of *Brucella abortus* infection, on sera collected from 4050 Wassermann samples in Syracuse, New York, showed 7.3% to contain abortus agglutinins. Examination of 955 similar samples of serum collected in New York City, showed 2.4% to agglutinate a *Br. abortus* antigen. *Br. abortus* agglutinins could not be demonstrated in serum from adults who had been drinking pasteurized milk containing such antibodies. Evidence is submitted to indicate that *Br. abortus* agglutinins in the blood serum are a result of active production by the living micro-organism which has invaded the body tissues. *Br. abortus* agglutinins may disappear from human sera very slowly. One serum titer was 1: 405, 2 yrs. after apparent recovery from undulant fever. Because of the variable antigenic properties of certain strains of *Br. abortus*, no specific serum titer can be established as diagnostic of undulant fever.—*Authors' conclusions.*

7428. **CRAIGIE, J. A method of drying complement from the frozen state.** *British Jour. Exp. Path.* 12: 75-76. 1931.—The apparatus consists of a vacuum pump (Geryk); a desiccator containing dry $CaCl_2$, a thin glass dish; and a support for the latter, the most suitable form being an X-shaped wire frame with the 4 ends fixed into corks. The dish should have ample clearance from the sides of the desiccator and the $CaCl_2$. The com-

plement is placed in the dish in a layer at least 1 cm. deep, the desiccator luted down with rubber-vaseline compound and evacuated. Slight bubbling takes place, the complement freezes solid and rapidly dries. The dried complement is easily pulverized and resuspended in distilled water, and the suspension is indistinguishable in appearance and hemolytic titer from the original. 1 lb. of dry $CaCl_2$ should be used for each 75 cc. of complement. The method can be applied to other biological fluids.—*J. Bland.*

7429. **CROMWELL, HOBART W., and MARJORIE B. MOORE. Studies on pollen and pollen extracts. III. Skin reactions to pollen extracts in rabbits.** *Jour. Immunol.* 20(2): 161-167. 1931.—Skin sensitivity to pollen extracts was demonstrated in actively immunized rabbits, using trypan blue as an aid, after Ramsdell's method. The reaction is specific, and is more delicate than the precipitin test as indication of an immune response. Localization of trypan blue also occurs in the abdominal fluid of immune animals following intraperitoneal injection of pollen antigen. Passive transfer of skin sensitivity from immune to normal rabbits was accomplished by use of large quantities of immune serum.—*Authors' summary.*

7430. **DAVIS, NELSON C. Uso experimental de uma vaccina cloroformada contra a febre amarella. [Experiments with yellow fever vaccine treated with chloroform.]** *Brasil-Med.* 45(12): 268-270. 1931.—Saline suspensions of virulent yellow fever virus (monkey livers) remained virulent for at least 28 days under treatment with chloroform, if preserved at 10° C. 1 cc. of this yellow fever vaccine (virus attenuated with chloroform) protected animals against only 1 test dose of an active virus administered 40 days after vaccination.—*Author's summary (transl. by A. de Assis).*

7431. **DIENES, L. The specificity of the tuberculin type of sensitiveness produced with the different substances of the eggwhite.** *Jour. Immunol.* 18(4): 279-283. 1930.—According to observations here described, sensitiveness of the tuberculin type produced in guinea pigs with egg globulin, crystalline egg albumin, and ovomucoid is specific to the preparation with which the animals are treated. The specificity of this type of sensitiveness, like that of anaphylactic sensitiveness, corresponds to the antigen specificity.—*L. A. Barnes (from author's summary).*

7432. **DONADEI, G. Essais d'immunisation par la voie nasale, contre la toxine du streptocoque isolé des scarlatineux.** *Soc. Internaz. Microbiol. Boll. Sez. Italiana* 3(1): 21-22. 1931.—Preliminary experiments showed that it is possible to vaccinate rabbits by the nasal route, as well as by the subcutaneous or intravenous routes, against infection by streptococci isolated from scarlatina cases.

7433. **DURAN-REYNALS, F. On the spontaneous immunization of rabbits to vaccine virus.** *Jour. Immunol.* 20(5): 389-391. 1931.

7434. **FASTING, GEORGE F. On the concentration of antistreptococcus serum.** *Jour. Infect. Dis.* 45(5): 360-365. 1929.—A modification of the Felton method for precipitating antibody-euglobulin in antistreptococcus sera is described. Use of ether in the diluent, for lowering surface tension, appears to have technical advantages and does not destroy the therapeutic merits of the antibody-euglobulin. The antibody fraction was administered intramuscularly and subcutaneously in a large number of cases, over a long period, without observation of complications or undesirable features of whole serum or of that concentrated by the salting method. Prolonged immunization of horses with green-producing streptococci produces a change in the euglobulin, manifested by appearance and increase of a fraction with an isoelectric point near that of normal blood, which carries down the bulk of the agglutinin and other antibodies, and which is of definite therapeutic value.—*Author's summary.*

7435. **FIALHO, AMADEU, et GENESIO PACHECO. Influence du système réticulo-endothélial sur la virulence bactérienne.** *Compt. Rend. Soc. Biol.* 98(17): 1562-1564. 1928.—Rabbits in which the reticulo-endothelial system was blocked by lithium carmine, were inoculated with attenuated *Bacillus pestis.* The authors conclude that the reticulo-endothelial system plays a part in the alteration of virulence of infections, since cultures taken from the animals showed greater virulence than the infecting cultures.

7436. **FINDLAY, G. M. The fractionation of anti-vaccinia serum.** *British Jour. Exp. Path.* 12: 9-12. 1931.—A pooled immune serum from a number of rabbits was treated with $(NH_4)_2SO_4$, and euglobulin, pseudoglobulin and albumin fractions were obtained. These were compared with the untreated serum in neutralisation, flocculation and phagocytosis experiments. In antivaccinia immune sera from rabbits, the immune body responsible for the protective action, for flocculation of the virus, and for stimulating phagocytosis of the virus, is associated with the globulin fraction.—*J. Bland.*

7437. **GLENNY, A. T., A. G. HAMP, and M. LLEWELLYN-JONES. The absorption of diphtheria antitoxin.** *British Jour. Exp. Path.* 12: 21-30. 1931.—Rabbits and guinea-pigs were given a known dose of antitoxin and bled at various intervals afterwards; the antitoxin value of the serum was then determined by intracutaneous tests. The total amount of antitoxin absorbed after each interval is then calculated by multiplying the antitoxic value per cc. of the serum by the serum volume taken as 1/20 of the body wt. There is a considerable difference in total amount of antitoxin absorbed into the blood-stream by different guinea-pigs injected subcutaneously with the same amount of serum; therefore, no conclusions can be drawn from experiments on a limited number of animals. There is no significant difference between amount of antitoxin absorbed, whether given diluted or undiluted. Rate of absorption of antitoxin depends on amount of protein injected, as compared with body wt. of animal, and is greatly affected by it. This influence of protein is greatest when the amount is large in relation to body wt. The average concentrated therapeutic serum is absorbed at least as rapidly as unconcentrated serum containing the same number of units, with small dosage; and more rapidly, with large dosage.—*J. Bland.*

7438. **GORDON, J. The action of Congo red on streptococcal haemolysin and on B. welchii haemolysin.** *Jour. Path. and Bact.* 34(44): 439-445. 1931.—Certain concentrations of solutions of Congo red neutralize the hemolysins of *Streptococcus haemolyticus* and *B. welchii.* These neutralizations are reversible; in the case of the streptococcus, addition of cuprammonium artificial silk adsorbs the Congo red and liberates the hemolysin. This method can not be used with *B. welchii,* as the hemolysin is destroyed by artificial silk. Reversibility with both the hemolysins of *Strep. haemolyticus* and *B. welchii* can be shown by the adsorption of Congo red on ox serum. Reversibility is best effected where the concentration of Congo red is just sufficient to neutralize the hemolysin. Congo red does not neutralize the hemolytic activities of solutions of saponin, sodium taurocholate or sodium ricinoleate.—*J. Gordon.*

7439. **GRAHAM, ROBERT, and FRANK THORP, Jr. Antigenic value of botulinum toxoids kept one year at ice box temperature.** *Jour. Immunol.* 20(4): 305-312. 1931.—An antigenic decline in botulinum toxoids of 30-60% over a period of 1-12 mo. was measured by the increased number of arbitrary units required to protect guinea pigs against lethal amounts of homologous toxins. None of the 11 toxoids that proved non-toxic in 1-unit doses later became toxic in the same amounts, notwithstanding an occasional toxoid-inoculated pig died of intercurrent infection. 7 of 11 samples of botulinum toxins A, B, and C containing 0.3-0.9% formalin became detoxified at 37-42° C. in 1 mo. The remaining 4 of 11 samples required 2-5 mo. for detoxification. One sample retained its original antigenic properties for 5 mo.; another for 3 mo.; 3 for 2 mo.; and 2 for 1 mo. 10 of the 11 toxoids were atoxic and antigenic in 2-unit

doses at 10-12 mo. of age. Rate of detoxification in botulinum toxoids by formalin and heat seemed uncorrelated with longevity of antigenic properties. One toxin with 20,000 guinea-pig-lethal doses per cc. required a longer period for detoxification than other toxins containing 10,000 guinea-pig-lethal doses per cc. However, no consistent difference in rate of antigenic decline was observed between toxoids prepared from toxins containing 10,000 and 20,000 guinea-pig-lethal doses per cc. The pH of 11 botulinum toxoids changed from an original titer of 7.6 in the inoculated media to an average of 6.7 in 7½ mo.—*Authors' summary.*

7440. **GRASSET, E. Sérum anti-typhoïdique concentré et purifié. Technique de préparation. Applications cliniques.** *Compt. Rend. Soc. Biol.* 106(10): 810-812. 1931.—A method for preparing polyvalent serum (typhoid and paratyphoid A, B and C bacilli) is described. This serum, used for over 600 cases of typhoid, has a marked curative action. Fractional precipitation with anhydrous Na_2SO_4 showed that the pseudoglobulin contains practically all of the therapeutic antibodies, thus providing a method of concentrating the antibodies to 4-6 times the concentration in the serum. Therapeutic action varies with amount of serum injected and is not accompanied by shock. The practical dose is 3-4 intramuscular injections of 20-40 cc. of concentrated serum, given at intervals of 24-48 hrs.—*E. Weiner.*

7441. **HARVEY, W. F. Variations in blood grouping.** *Indian Jour. Med. Res.* 17(4): 1307-1311. 1930.—5 blood groups have emerged by testing the blood of a limited number of individuals strictly against every other, instead of by means of a standard serum. There is then a possibility that still more groups might be obtained if this method of testing were carried out. The gradation of agglutination found within the groups, as judged by using a time unit as a measure, points to the possibility of one group merging into another and to the possible existence of variant individuals of whom it can not be said positively that they belong to one or another of the selected groups or to a new group.—*Author's summary.*

7442. **HERHOLZ, GÜNTHER. Weitere Erfahrungen mit der aktiven Scharlachimmunisierung.** *Zeitschr. Kinderheilk.* 50(6): 680-690. 1931.—About 1400 children in an institution were injected with Dick toxin (12,500 skin test doses); 9 (0.6%) developed scarlatina more than 2 weeks after the last injection. Of 266 unvaccinated children, 14 (5.2%) were attacked.—*G. Herholz (transl. by L. C. Havens).*

7443. **JULIUS, H. W. Over agglutinatie van carcinoomcellen. [Agglutination by carcinoma cells.]** [With English, French and German summaries.] *Nederl. Tijdschr. Hyg., Microbiol. en Serol.* 6(1): 71-79. 1931.—Based on a series of experiments, the writer concludes that the phenomenon of agglutination in cancer cells, as discovered by Waterman, is not specific for carcinoma. A hypothesis is introduced that the reaction may be classed in the well-known system of heterogenetic antibodies and their heterophilic (Forssman's) antigen.—*Author's summary.*

7444. **KOLLER, SIEGFRIED, und MAX SOMMER. Zur Kritik der von S. Wellisch angewandten mathematischen Methoden in der Blutgruppenforschung.** *Zeitschr. Rassenphysiol.* 3(1): 27-44. 1930.—13 mathematical papers written by Wellisch on the theory of blood groups are criticized, and numerous serious mathematical errors are pointed out. A single positive result could not be obtained from all these works. In his rebuttal, Wellisch only defends a moot point.—*S. Koller (transl. by A. S. Wiener).*

7445. **KOULIKOFF, W., P. SMIRNOFF, et M. BOBKOVA. Conditions physico-chimiques de la thermostabilité de l'antitoxine diphtérique.** *Compt. Rend. Soc. Biol.* 98(17): 1503-1504. 1928.—Antitoxin (300 units per cc.) was acidified with N/10 HCl to pH 3.6-2.6 and heated 10 min. at 100°. No precipitation occurred until the solution was neutralized. The precipitate redissolved at pH 7.9-8.2. The serum retained 60-120 units immunizing power per cc. after this treatment.

7446. **KRITSCHEWSKI, I. L., und K. A. FRIEDE. Über die zelluläre Natur des anaphylaktischen Schockes. VII.** *Zeitschr. Immunitätsforsch.* 64(5/6): 493-509. 1929.—Experiments were carried out on blood vessel preparations (Friedberger & Seidenberg) of the hind legs of guinea pigs sensitized with sheep erythrocytes and of the ears of rabbits sensitized with sheep erythrocytes or horse serum. The blood vessels were thoroughly perfused with Ringer-Locke solution before addition of antigen. Controls were done with preparations from normal animals. Further experiments were done on blood vessel preparations of rabbit ears thoroughly perfused with Ringer-Locke solution and kept in the refrigerator over night before the test. The authors found that when antigen was added to guinea pig and rabbit blood vessel preparations previously perfused free of antibodies, the vessels contracted. Intensity of contraction was independent of amount of antibodies in the blood. The negative results of some of the preparations kept in the refrigerator over night are attributed to partial necrosis of the preparations. The authors believe that these experiments confirm the importance of cellular antibodies and their independence of humoral antibodies in anaphylaxis.—*H. L. Gruehl.*

7447. **KYES, PRESTON, and ROBERT T. PORTER. The antigenic properties of fibrinogens.** *Jour. Immunol.* 20(2): 85-88. 1931.—In further studies on blood fibrinogen as a source of serum shock, the authors prepared fibrinogen from the blood of Plymouth Rock cockerels, and administered 6 injections of 5 cc. of standard solution (i.e., dissolved in a volume of dist. water equal to the original volume of plasma from which the fibrinogen was obtained), at 2½ day intervals, into rabbits. About ½ the rabbits survived. As little as 0.005 cc. of this immunized rabbit serum precipitated fibrinogen from a dilution (1:20 of a 2% Na citrate solution) of the "standard." This anti-fibrinogen immunization was specific for fibrinogen from fowls; that from sheep or horses was not precipitated.

7448. **LEBEDJEWA, M. N., und L. B. LEVINSON. Über die Anaphylaxie gegenüber Lipoiden.** *Zentralbl. Bakt. I. Abt. Orig.* 117(7/8): 519-535. 1930.—A brief review of the literature is given. Guinea pigs were sensitized with 5 daily doses of 1.5 cc. of a mixture of lecithin and hog serum prepared by evaporating a 1% alcoholic solution of lecithin, redissolving in an equal volume of 1:10 hog serum, and holding at room temp. for at least ½ hr. Test was carried out 14 days later by the blood vessel preparation method of Friedberger and Seidenberg, perfusing with serum-lecithin mixture. Controls were done with serum and with lecithin. Sensitization was demonstrated to serum, but not to lecithin. Preparations from a desensitized animal showed similar results. Attempts to sensitize paramoecia to lipoids also failed. The authors conclude that lipoid anaphylaxis does not occur, since the reactions obtained with lipoid-serum mixture were reactions to serum alone.—*H. L. Gruehl.*

7449. **LEHNER, E., und E. RAJKA. Künstliche Sensibilisierung und Desensibilisierung der menschlichen Haut unter Vermittlung von Schleppersubstanzen.** *Zeitschr. Ges. Exp. Med.* 71(1/2): 128-136. 1930.—Artificial sensitization of human skin can be produced in almost every individual if the depot method of application is used. Here the substances are always applied to the same place on the skin. With some materials, application of the single substance is sufficient; with others, especially definite chemical substances, it is necessary to add some aiding substance. The best of these are blood serum, other protein-containing substances, cholesterol, and dextrose. Sensitization begins in the neighborhood of the depot and gradually extends to the entire skin. On further application to the depot, desensitization occurs; this also begins at the depot and extends over the entire body surface.—*J. T. Myers.*

7450. **LEWIN, J., et L. POJARISKAJA. Les réactions**

de l'anaphylaxie sur l'intestin isolé et son application. *Rev. Hyg. et Méd. Prévent.* 52(4): 267-270. 1 fig. 1930.—A preliminary series of experiments to determine the dosage in the isolated intestine reaction and a parallel series contrasting the efficacy of this reaction with that of the precipitin test, showed the former the more sensitive. The authors advance several reasons for use of the smooth muscle experiment in legal medicine.—*H. L. Gruehl.*

7451. **LUDFORD, R. J.** Resistance to the growth of transplantable tumours. I. The influence of vital staining on induced resistance. *British Jour. Exp. Path.* 12: 45-48. 1931.—Mice were vitally stained with repeated inoculations of trypan blue and were immunized by injection of finely minced mouse embryo skin. They were then transplanted with tumor. The effect on these mice was compared with similarly transplanted normal mice and immunized mice untreated with trypan blue. Vital staining with trypan blue breaks down the immunity to tumor transplantation induced by inoculation of embryo skin emulsion. A local cellular reaction in the immunizing process is shown to occur, and it seems most probable that vital staining modifies this reaction in some manner so as to affect the general reaction of host to inoculated tumor cells.—*J. Bland.*

7452. **LUDFORD, R. J.** Resistance to the growth of transplantable tumours: II. The influence of dyestuffs and of colloids on natural resistance. *British Jour. Exp. Path.* 12: 108. 1931.—Trypan blue, vital new red and various inorganic colloids—substances of very different chemical and physical properties—are capable of breaking down the resistance of mice to the growth of transplantable tumors. However, these substances have 2 properties in common: they are segregated by certain cells of the animal body, especially the macrophages; and, in the doses used, they reached the limit of toxicity. —*J. Bland.*

7453. **LUMIÈRE, AUGUSTE.** Le néologisme "anaphylaxie." *Rev. Gén. Sci. Pures et Appl.* 42(9): 258-260. 1931.—Note containing a brief history of our knowledge of anaphylaxis.

7454. **MARRACK, J., and F. C. SMITH.** Quantitative aspects of immunity reactions: the precipitin reaction. *British Jour. Exp. Path.* 12: 30-34. 1931.—The amount of precipitate obtained when antigen (horse-serum pseudoglobulin) and antibody (rabbit serum) were mixed in optimum proportions, was relatively independent of conditions under which precipitation took place. Addition of non-specific proteins had no effect and the effects of variation in concentration of electrolytes and temp. at which flocculation took place were appreciable only when the antigen-antibody mixture was much diluted. When antigen is in excess and the volume large, the amount of precipitate is greatly increased by addition of $BaCl_2$. This is thought to be due to neutralization of the negative charge of an insoluble suspension. The mixture of horse-serum pseudoglobulin and its antibody is slightly soluble in 0.9% NaCl. The precipitate is composed of protein; no substances soluble in fat solvents were detected.—*J. Bland.*

7455. **MAZZETTI, GIUSEPPE.** Comportamento del bac. del carbonchio negli organi di cavia uccisa con un ceppo asporigeno di tale germe e tenuti alla temperatura del ghiaccio fondente. (Esper. in "vitro.") [Behavior of anthrax bacilli in the organs of a guinea pig killed by a non-sporulating strain and kept at the temperature of melting ice. (In vitro test.)] *Boll. Soc. Italiana Biol. Sper.* 3(8): 1195-1197. 1928.—The author in previous experiments had demonstrated that the organs (particularly the spleen) of a guinea pig killed with anthrax bacilli and kept at the temp. of melting ice rid themselves gradually of these organisms. The author, using a non-sporulating, virulent strain of anthrax bacillus, found that the phenomenon in vitro was the same as that in the cadaver. The spleen is the organ showing a true and specific activity inhibiting the survival of anthrax bacilli even at low temp. The other organs—some more, some less—keep the organism viable. In muscular tissue it was still alive after 2 mo.—*G. Mazzetti (transl. P. Hillkowitz).*

Paris* 1928(5): 321-324. 1928.—The toxicity of viper serum is not affected by ultraviolet irradiation; its antigenic power is destroyed, as is its power of neutralizing rabies fixed virus.

7465. **PITTMAN, MARGARET, and I. S. FALK.** Studies on respiratory diseases. XXXIV. Some relations between extracts, filtrates and virulence of pneumococci. *Jour. Bact.* 19(5): 327-361. 1930.—A saline extract of pneumococcus prepared by Rosenow's method decreased the phagocytosis of avirulent organisms, reduced the opsonic content of serum, only slightly increased the virulence of a borderline culture after it had been transferred several times in presence of the extract, and failed to influence the virulence of an avirulent pneumococcus. When an extract of pneumococcus produced by freezing and thawing was inoculated into white mice

it produced purpura. This extract protected mice against infection with a pneumococcus of low virulence, when the extract had preceded the culture by 24 hrs. The protection lasted only as long as purpura was visible. If the extract was given simultaneously with culture or after a slight infection had developed, fatality resulted. When the extract followed the culture inoculation, the purpuric reaction was absent or less severe. The borderline culture, after having been transferred rapidly in a medium containing some of the extract, was not changed in virulence. Fresh filtrates of pneumococcus prepared with several different media were not sufficiently toxic for laboratory animals to cause death, but they tended to increase the localization power of avirulent pneumococci when mice were given the 2 substances simultaneously. Virulence of pneumococci was not significantly affected when they were transferred rapidly in presence of old culture filtrates containing a large amount of soluble specific substance, in enriched media and in media containing substances that lower and raise the electrophoretic potential of bacterial cells. Rabbits inoculated intravenously with 10 small doses of pneumococcus filtrate developed sufficient immunity to cause a localization of pneumococci in the lungs.—*Authors' recapitulation.*

7466. **PREDTECHENSKY, S. N.** Production of potent antitetanic serum. *Jour. Immunol.* 20(2): 143-148. 1931.—In the method described, a ground-immunity was obtained by a few injections of toxin and antitoxin; then the horses rested during 3-4 mo.; after that, they were immunized with doses of toxin doubled each time. The serum content of antitoxin reached 1500 or more units per cc.—*Author's summary.*

7467. **RAMON, G.** Sur la stabilité des propriétés de l'anatoxine diphtérique. *Compt. Rend. Soc. Biol.* 98(17): 1504-1506. 1928.—Diphtheria anatoxin kept at 3-4° C. or at room temp. was found, after 5 yrs., to have retained its immunizing power and not to have become toxic. Refrigerated serum precipitated antigens most rapidly.

7468. **RAMON, G., R. LEGROUX, et M. SCHOEN.** Sur l'anatoxine diphtérique extraite du floculat spécifique. Ses propriétés. *Compt. Rend. Soc. Biol.* 106 (10): 779-782. 1931.—Diphtheria anatoxin extracted from the specific flocculate retained its flocculating power after heating at 100° C. for 10 min. The dissociating power was also retained. The immunizing power was tested by injecting guinea pigs with samples of the recovered anatoxin, the value of which was determined by flocculation. After 1 mo. the animals were killed and the average amount of antitoxin was measured. The anatoxin, heated to 100°, had an immunizing power equal to that of anatoxin derived directly from toxin. This method of extraction of anatoxin provides a simple means of concentrating this antigen, since most of the nitrogenous substances are removed in the process.—*E. Weiner.*

7469. **RICHET, CHARLES, fils, [JEAN] DUBLINEAU, et RAYMOND COUDER.** La bactériolyse tissulaire du bacille de Koch. *Jour. Physiol. et Path. Gén.* 29(2): 277-287. 1931.—Bacteriolysis of Koch's bacillus can be brought about by a relatively simple, thermolabile lysin found associated with the proteins of liver, muscle and blood corpuscles.—*W. R. Fearon.*

Gén.* 29(2): 294-298. 1931.—In certain animals, onset of tuberculosis was retarded by simultaneous inoculation with meat juice or extract of blood corpuscles. This is believed to be due to the agent concerned in the beneficial results sometimes obtained in zomotherapeutic treatment of tuberculosis.—*W. R. Fearon.*

7471. **ROSLING, EYVIND.** Undersøgelser over difteridisposition og difteriimmunitet med saerlight henblik paa blodgrupper, Schickreaktion og arvelighedsforhold. [Investigations on predisposition and immunity to diphtheria, with special reference to blood groups, Schick reaction, and inheritable conditions.] [With English summary.] 135p. Arnold Busck: Copenhagen, 1928.—Determination of the blood groups of 339 normal children below 15 yrs. old yielded figures deviating from those of Thomsen for individuals over 65 yrs. old. There is some reason to believe that the proportionality between individual blood groups undergoes a change with advancing age, group II increasing at the expense of the other groups. Other investigations seem to point to the same conclusion. Blood group as well as sex influences the course of diphtheria, post-diphtherial pareses occurring more frequently and being more severe in group I than in group II; within each group; also these conditions are more frequent and more severe in boys than in girls. Cardiac complications are more frequent in group I than in group II, without displaying differences with regard to sex. Variations in the same morbidity curves of the same disease, and the cause of such variations, are discussed. A detailed survey of the history, technic and course of the Schick reaction and its variations is given. Schick reactions differ in the 2 sexes, there being more Schick-negatives among boys than among girls. Some statements regarding the duration of negative Schick reactions are criticized. It has been pointed out that the limit between positive and negative Schick reactions must be supposed to lie about 1/100 unit of antitoxin per cc. of serum. A difference in the relations of the Schick reaction within the different blood groups has not been observed. The author's investigations show that, even though clinical diphtheria is more frequently met in Schick-positive than in Schick-negative individuals, it is not infrequently observed in the latter. By following the Schick reaction during the course of mild cases which have not been treated with serum, and by re-examining patients with severe diphtheria sometime after onset, it has been shown that a production of antitoxin demonstrable by means of the Schick reaction commences rather late or in many cases fails to occur. Antitoxin production could most frequently be demonstrated in patients with mild diphtheria, whereas among patients who had had a severe diphtheria only 30% were found to be Schick-negative when examined 5-11 mo. after onset. The author's investigations bearing on the relations of the Schick reaction in the laboring classes of Copenhagen are recorded. In these as well as in other investigations, a distinct rise is witnessed in the number of Schick-negative individuals at age 13. There are 3 forms of immunity against diphtheria: (1) the capability of producing antitoxin, (2) a not yet definitely known function depending on the suprarenal capsules, and (3) antibacterial immunity expressed by pseudoreaction to the Schick test. Immunity against diphtheria is not merely a question of antitoxin; it depends also on a series of other factors, such as sex, blood group, the beginning of puberty, the ovarial function, and possibly also on a great many others, of which the importance and interrelations are as yet far from being clear.—*K. C. Berthelsen.*

7472. **ROSSET, WILLY.** L'action du choc par centrifugation sur la résistance du cobaye à l'infection par le Mycobacterium aquae Galli-Valerio. *Zeitschr. Immunitätsforsch.* 64(5/6): 510-520. 3 fig. 1929.—The problem was to determine whether a diminution of individual resistance could transform a non-pathogenic bacillus into a pathogenic one. The resistance of guinea pigs was lowered by daily rotations of 1 min. duration in a specially constructed centrifuge (Galli-Valerio). Normal guinea pigs were infected, subcutaneously or intraperitoneally, with *M. aquae* and then subjected to rotation. Controls were infected without rotation. The authors found that centrifugalization influenced the localization of the micro-organism and that it inhibited bacteriolysis, allowing the animals to become infected more easily. The central nervous system was never affected. The action of centrifugalization suggested an increase of virulence of *M. aquae* by lowering the resistance of the organism which it infected.—*H. L. Gruehl.*

7477. **SHIBUYA, S. The relation between tuberculosis and typhoid. Experiments on animals.** [In Japanese, with English summary, p. 27.] *Jour. Oriental Med.* 14 (3): 1931.—Inoculation of typhoid vaccine into tuberculous rabbits slightly encouraged phagocytosis against tubercle bacilli, but had no effect on outcome of the disease. In tuberculous rabbits inoculated with typhoid vaccine the output of agglutinin against typhoid bacilli was smaller, and the disappearance of agglutinin was quicker than in normal rabbits similarly immunized. Tuberculous rabbits immunized by typhoid vaccine showed less vigorous phagocytosis for a time. The process gradually became slightly more vigorous than in tuberculous rabbits not immunized by typhoid vaccine, but the outcome of the disease was not noticeably affected. Rabbits immunized by typhoid vaccine showed no increase of agglutinin against typhoid bacilli due to their infection with tuberculosis, but the agglutinin disappeared sooner than in non-tuberculous rabbits. The author found no specific relation between the 2 diseases with respect to phagocytosis or agglutination.—*Author's summary.*

7478. **SICKLES, GRACE M. Local skin reaction obtained by intravenous injection of agar following intracutaneous inoculation of meningococcus toxin.** *Jour. Immunol.* 20(2): 169-172. 1931.—Intravenous injections of agar may be followed by reactions in skin areas prepared by injections of meningococcus toxic filtrate. Local reactions did not occur at the site of intracutaneous injections of agar when followed by intravenous injections of agar or of toxin. No reactions were obtained after intravenous injection of other non-bacterial substances such as galactose, gelatin, serum or India ink, following intracutaneous injection of meningococcus toxic filtrate.—*Author's summary.*

Assoc.* 32(2): 241-243. 1931.—3 improvements in the technique of the rapid agglutination test are reported: a highly stained (gentian violet) antigen; a white porcelain plate for a contrasting background, thereby eliminating the necessity of artificial lighting; and standardized pipettes for delivering accurate quantities of blood and antigen.—*Authors' summary.*

7489. **COMINOTTI, LUIGI.** Der Kampf gegen die Maul- und Klauenseuche mittels der Simultanimpfung in der Lombardei. *Deutsche Tierärztl. Wochenschr.* 39 (32): 497-499. 1931.—Simultaneous inoculation with highly potent serum and virus very effectively protected against both the malignant and mild forms of foot-and-mouth disease.

7490. **CURASSON, G.** La prophylaxie de la peste bovine. *Rec. Méd. Vét. École d'Alfort* 3(4): 161-175. 1930.—A comprehensive review of immunization methods against rinderpest, with bibliography.

7491. **FORTNER, J.** Immunitätsbeziehungen zwischen Variolavakzine und Geflügelpocken beim Huhn. *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39(1/2): 150-159. 1931. —The author concludes that it is not possible to protect fowls against variola vaccine virus with fowl-pox virus, or vice versa. The variola vaccine gave a slight protection against a reinoculation, while the fowl-pox virus gave complete protection against a reinfection with homologus virus.—*L. D. Bushnell.*

7492. **HADLEY, F. B., and W. E. WELSH.** On the persistency of the agglutination reaction for Brucella abortus. *Cornell Vet.* 21(3): 286-291. 1931.—The data presented demonstrate that within 2 yrs. a relatively large number of high titer reactors became low reactors, while a smaller number became non-reactors. On the other hand, all the low titer reactors in the herd under discussion became non-reactors. Detailed results are given in tables.

7493. **HÄGERSTAD, GÖSTA.** Kvarkvaccinens immuniserande förmåga. III. [Immunizing value of strangles bacterin III.] [With English summary.] *Skandinavisk Vet.-Tidskr.* 21(9): 289-292. 1931.—The immunizing value of strangles bacterin was tested on a horse after a 2nd subcutaneous inoculation with 15 cc. of 0.1 volume-% of strangles bacterin (strangles streptococci killed by boiling and suspended in phenolated saline), as compared with the immunizing power after a 1st inoculation carried out in the same way. The immunizing value was estimated by the protective action of the horse-serum on mice, which, the day after treatment with serum, had been infected with a strangles strain which killed non-treated mice within 24 hrs. The serum (0.02 cc.) was injected subcutaneously. Both after the 1st and the 2nd inoculations, an increased immunizing value followed within 1 week and attained its maximum height in 3 weeks; subsequently the immunity-value decreased,—quickly after the 1st inoculation but more slowly after the 2nd.—*From author's summary.*

7494. **KARMANN, P.** Die Milzbrandimpfung nach Besredka. *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39 (1/2): 51-69. 1931.—The author describes results of treating white mice, guinea pigs, rabbits and sheep, cutaneously and intra-cutaneously, with Pasteur anthrax vaccines I and II (Besredka method). Some of the animals failed to survive treatment, but those which did showed a relatively high degree of immunity. The intracutaneous method was most satisfactory, since the cutaneous method led to more severe vaccination losses. —*L. D. Bushnell.*

7495. **KATRANDJIEFF, K.** Sur les propriétés précipitogènes du lait de Bufflesse. *Compt. Rend. Soc. Biol.* 98(17): 1508-1510. 1928.—Antisera of buffalo milk are specific for dilutions above 1 part per 100; below this dilution they precipitate cow milk, although more slowly. Cow antisera precipitate buffalo milk rapidly, and goat antiserum is specific only at about 1 part in 4,000. Equalization of protein content caused the cow antiserum to retain its specificity. The author concludes that casein played the principal rôle in precipitation.

7496. **LÜCKE.** Vergleichende Untersuchungen über die intrakutane Anwendungsmethode des Tuberkulins. *Zeitschr. Veterinärk.* 43(8): 286-297. 1931.—Intradermal tests, as compared with those on the conjunctiva, are at least of equal value; the reaction is clearer and permits a more objective estimate of results, and is not so easily effaced.

7497. **MENCK, FR.** Die Abortus-Klärungsreaktion (A.K.R.) eine neue einfache und sichere Methode zur Serodiagnose des Abortus Bang. [The abortus clearing reaction: A new and sure method for serodiagnosis of contagious abortion.] *Berliner Tierärztl. Wochenschr.* 47(12): 178-180. 1931.

7498. **NORDBERG, ÅKE.** Immuniseringsförsök på möss med rödsjukeympämne. (Immunization experiments with swine erysipelas vaccine on mice.) [With English summary.] *Skandinavisk Vet.-Tidskr.* 21(8): 231-247. 1931.—There are swine erysipelas bacilli which are perfectly avirulent for mice but which give rise in them to immunity against subsequent infection with virulent bacilli. It should be possible to employ this characteristic for diagnosing avirulent swine erysipelas bacilli. The latter may occur in company with virulent swine erysipelas bacilli, with which they may be obtained in cultures. From cultures of a mixture of the virulent and avirulent bacilli, the latter can be obtained pure by carrying for a long time on artificial media without mouse-passage, in which process the virulent form is so greatly checked in development that it finally dies. Inoculation with the avirulent bacilli (0.2 cc. of serum bouillon culture, 24 hrs. old) increases in high degree the power of resistance of inoculated mice against subsequent infection with the virulent bacilli. This was observed within 7 days after inoculation, and remained undiminished for a further 10 weeks.—*Author's summary.*

7499. **SCHAFFER, JACOB M., ANGUS D. MacDONALD, WALTER J. HALL, and HUBERT BUNYEA.** A stained antigen for the rapid whole blood test for pullorum disease. *Jour. Amer. Vet. Met. Assoc.* 32(2): 236-240. 1931.—The new antigen consists of a suspension of *Salmonella pullorum* in 0.85% NaCl adjusted to a turbidity 75 times that of Standard No. 1 of the McFarland scale, killed and preserved by addition of 1% liquor formaldehydi U. S. P., and stained by addition of 0.03% crystal violet. The test may be made by mixing 1 drop of antigen with a rather heavy blood smear on a glass plate.—*Authors' summary.*

7500. **SCHMEY, und HENKE.** Das Guttadiaphot in der Tierheilkunde. *Arch. Wiss. u. Prakt. Tierheilk.* 61 (6): 465-484. 4 col. fig. 1930.—The guttadiaphot is a non-specific blood test, useful in veterinary medicine along with other methods in establishing a diagnosis of tuberculosis or of parasitic invasion. The guttadiaphot is principally influenced by the age of the lesion (tuberculosis) or the severity of the invasion (parasites). The interpretation must be made with respect to age and general condition of the animal, since old age and poor condition may give a positive result.—*Authors' summary (transl. by I. E. Newson).*

7503. ADAMS, A. R. D. The action of various sera, in vitro, on the gut and salivary gland forms of T. rhodesiense and T. gambiense from Glossina palpalis. *Ann. Trop. Med. and Parasitol.* 25: 299-312. 1931.—This paper deals with the action in vitro of a variety of sera (mammalian, avian, reptilian) on the gut and salivary gland forms of 4 strains of *T. rhodesiense* and of 1 strain of *T. gambiense*, obtained from experimentally infected *G. palpalis*. The experiments were conducted at 24°-29°C., and it was found that all fresh, complement-containing sera are rapidly lethal to the gut forms of the *Trypanosoma rhodesiense* and *T. gambiense* strains used. It is shown that removal of hemolytic complement destroys the trypanocidal action of these sera, and that in these deactivated sera the gut forms survive up to 24 hrs. The salivary gland forms are not killed by hemolytic complement, thus differing from the gut forms. Presence of an anticomplementary substance in saline extracts of salivary glands and of mid-intestines of *G. palpalis* was demonstrated, and it was found that blood is deprived of its complement within 10 min. after ingestion. It is due probably to the presence of this anticomplementary substance that feeding of fresh blood fails to sterilize the infected fly.—*A. R. D. Adams.*

7504. AMAKO, T. H. Ueber die Rolle der Milz und der Leber bei der Antikörperbildung bei experimenteller Trypanosomiasis. *Zentralbl. Bakt. I. Abt. Orig.* 117 (7/8): 470-479. 1930.—The author studied agglomeration [agglutination] in *Trypanosoma gambiense*, using rabbits immunized with a trypanosome vaccine as source of immune serum. He concludes from the following type of experiments that the spleen and liver are the chief sites of antibody formation: Splenectomy or partial destruction of the liver by hepatotoxin (a rabbit antiliver serum) or chloroform 1-2 days before immunization, significantly lowered the titer of the agglutinins as compared to normal controls. The same procedure at height of antibody formation had no such effect. Transplantation of spleen and liver of immunized rabbits into normal rabbits was followed by antibody production. Direct injection of small amounts of trypanosome vaccine into liver or spleen led to demonstration of antibodies in the peripheral blood more quickly and in higher titers than intravenous injection. Examination of liver and spleen extracts taken at various stages during immunization showed antibodies earlier and in greater amounts than in other sites. Throughout, the spleen is more important in antibody formation than the liver. When the spleen is removed, its loss of function is compensated for by the liver; loss of liver function is similarly compensated for by the spleen.—*W. H. Taliaferro.*

7505. DUKE, H. LYNDHURST, and J. M. WALLACE. "Red cell adhesion" in trypanosomiasis of man and animals. *Parasitology* 22(4): 414-456. 1930.—An adhesion phenomenon is described in which, under certain circumstances, red blood corpuscles of primates adhere to trypanosomes. The substance responsible for this phenomenon, designated "adhesin," appears in the blood of an animal in the course of its infection with trypanosomes, whether or not the animal is treated with trypanocidal drugs. When citrated blood of such animals is mixed with a blood containing trypanosomes, and if one blood is that of a primate, red cell adhesion occurs. The mixed citrated bloods (1 vol. blood+1 vol. 2% citrated saline) are placed on a slide, covered with a coverslip and observed under the microscope, readings being taken 10 min. after mixing. A negative reaction does not exclude trypanosomiasis, but a positive reaction invariably indicates recent or actual infection. No absolute specificity was obtained in this reaction; *T. gambiense* adhesin bloods not uncommonly react with *T. rhodesiense*. It was impossible to differentiate between "passage" and "relapse" strains by this test. 216 treated and untreated cases of human trypanosomiasis in Uganda Protectorate were examined and positive reactions with *T. gambiense* obtained in 38.8%; of 19 untreated cases, 14 gave a strongly positive reaction. Of 92 cases tested with both trypanosomes, 6 gave positive reactions with *T. rhodesiense* as well as with *T. gambiense*, but none reacted to *T. rhodesiense* alone. Control tests with 96 natives and 9 Europeans, without trypanosomiasis and apparently healthy, were all negative. A preliminary study of the mechanism of the test showed that the red cells of some primates are essential. The relationship between red cell adhesion and the adhesion phenomenon described by other workers is discussed, and evidence is produced suggesting that all the reactions are due to the same hypothetical substance, "adhesin."—*H. L. Duke.*

7506. [KONSTANSOV, S. V.] КОНСТАНСОВ, С. В. Противомалярийные иммунитет, вакцина и вакцинация. [Anti-malarial immunity, vaccine and vaccination.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии. (*Russ. Jour. Trop. Med., Med. & Vet. Parasitol.*) 7(10): 645-657. 1929.—Vaccination of 5 patients was done with an anti-malarial vaccine. Quinine therapy was abandoned, since its plasmodicidal action prevents development of antiplasmodic factors. 2 cases had to be interrupted; in 3 the results, though slow to develop, were positive. In the periods of normal temp., plasmodial content of the blood gradually and steadily decreased and plasmodia were exclusively mature schizonts. Prior to complete disappearance of plasmodia, they showed signs of degeneration and necrosis. Clinical phenomena, morphological picture of blood and changes in the leucocytic formula fully corresponded to the apparent development of immunity.—*B. Van Rosen.*

7507. NIESCHULZ, OTTO, und A. BOS. Über den Einfluss der Milz auf den Infektionsverlauf von Surra bei Hunden. *Deutsche Tierärztl. Wochenschr.* 39(31): 488-489. 1931.—In 5 splenectomized dogs, the course of the trypanosomiasis differed essentially from that in 4 controls. In general, infections in splenectomized animals were more severe and of shorter duration.

7508. PFANNENSTIEL, W., und B. SCHARLLAU. Die Einwirkung menschlichen Blutes auf Dourineinfektionen. *Arb. Staatsinst. Exp. Ther. u. Georg Speyer-Hause, Frankfurt a. M.* 21: 133-151. 1928.—The trypanocidal principle of normal human blood is contained in the serum and not in the platelets, leucocytes or erythrocytes. Extraction with alcohol or precipitation of the globulin failed to give the trypanocidal principle in pure form; but that substance was enriched if the serum was dried, pulverized, and taken up in physiological saline. By injection of suitable doses of powdered human serum, infections with dourine trypanosomes were permanently cured. Mixing human serum or serum powder with inactive animal sera diminished the trypanocidal effect. Combined treatment with dried serum and germanin or neosalvarsan considerably increased the curative effect of these components.—*Authors' summary (transl.).*

7509. RAY, IYOTIS CHANDRA. Intrakutanreaktion zur Diagnose der experimentellen Leishmaniosen (Kala-azar, Orientbeule). *Arch. Schiffs- u. Tropen-Hyg.* 32(7): 369-376. 1928.—In 6 hamsters newly infected with kala-azar the intracutaneous reaction was positive with kala-azar antigens. A rabbit strongly immunized to a culture of kala-azar gave a strong positive reaction to a glycerine kala-azar antigen and a light reaction to an alkaline antigen. Of 2 hamsters locally infected with

kala-azar, 1 gave a light positive reaction, the other a negative with *Leishmania tropica* antigen. One rabbit strongly immunized to a culture of *L. tropica* gave a lightly positive reaction to *L. tropica* antigen. In hamsters infected with kala-azar and 1 rabbit immunized to kala-azar, the Oriental boil antigen gave a negative reaction. Against this, 1 of 2 hamsters immunized to Oriental boil and 1 rabbit immunized to *L. tropica* gave positive reactions to Oriental boil antigen. The author concludes that the reaction is specific.—*D. Koch.*

7516. **CONKLIN, R. L., and ALEX. D. BAKER.** Presence of the Lancet fluke, Dicrocoelium dendriticum (Rudolphi 1819), in Canada. *Jour. Parasitol.* 17: 18-19. 1930. *D. dendriticum* was found in sheep livers from the Lake St. John region of Quebec and from Nova Scotia. It has not previously been recorded from Canada or the U. S. A.—*A. D. Baker.*

7517. **CORRADI, GIOVANNI.** Della malaria latente e in particolare della sua attivazione spontanea e provocata. [Latent malaria and particularly its spontaneous and artificial activation.] 86p. Fresching: Parma, Italy, 1928.

7518. **DEY, DEBAKAR,** Generalized infection of Coenurus serialis or Multicepa gaigerii in goats. *Far East. Assoc. Trop. Med. Trans. 7th Congr.* 3: 656-657. 2 pl. (1 col.). 1927[1928].—Review of the author's previous studies and history of a case of generalized infection, including the brain.

7519. **[DIAGILEVA, A.]** ДЯГИЛЕВА, А. Случай множественного цистицеркоза мозга. [A case of multiple cysticercosis of the brain.] Русский Журнал Тропической Медицины. [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 6(10): 655-657. 1 fig. 1928.—80-100 *Cysticercus cellulosae* were found in the brain of a 14 year old boy. No worms were found in the intestines. Most parasites were partly disintegrated, and only isolated specimens fully preserved.

7520. **DOBELL, CLIFFORD** (with cooperation of **ANN BISHOP**). Researches on the intestinal protozoa of monkeys and man. III. The action of emetine on natural amoebic infections in Macaques. *Parasitology* 21(4): 446-468. 1929.—Most spp. of *Macacus* appear to be parasitized with two strains of an amoeba indistinguishable from *Entamoeba histolytica.* Double iodide of emetine and bismuth was administered daily per os to 5 healthy young tame acclimatized monkeys. By careful administration the total infections of this amoeba were repeatedly eradicated from 4 of the 5 animals, with no or only temporarily harmful effects to the hosts; on the other parasites, *Entamoeba coli, Endolimax nana, Enteromonas* sp., etc., it had no curative effect. Emetine affects the protozoon fauna of *Macacus* spp. as it does that of man, and therefore these monkeys may be used for the study of remedies for human amoebic dysentery. —*M. W. Kamm.*

7521. **DU, S. D.** Preliminary report on a fluke found in shrimps in Chengtu and its environs. *China Med. Jour.* 44(7): 679-683. 1 pl. 1930.—Of 769 shrimps dissected in Szechuan, 425 were river and stream shrimps. The infested shrimps (40.6%) came entirely from rivers and streams, none from ponds, and were found during

the spring and summer months. These flukes are not necessarily pathogenic to man as they lost their vitality in 10-20 min. on immersion in 0.3% HCl.

7522. [DZHAPARIDZE, P. S.] ДЖАПАРИДЗЕ, П. С. Клинические формы анкилостомидозов. [Ancylostomae in Abkhazia.] Русский Журнал Тропической Медицины. [*Russ. Jour. Trop. Med.*] 6(9): 584-587. 1928.—*Ancylostoma duodenale* and *Necator americanus* were found in many cases. Worm carriers showed various degrees of anemia, and lesions of gastrointestinal tracts and of the nervous system.

7523. **FAUST, E. C. Infection experiments in man and other mammalian hosts with Sparganum stage of Oriental diphyllobothrids.** *Proc. Soc. Exp. Biol. and Med.* 26(3): 252-254. 1928.—Collections from man, and from domestic animals and their wild relatives, in China included *Diphyllobothrium cordatum* from dog, *D. mansoni* from cat, wild-cat, and leopard, *D. ranarum* from cat, and *D. houghtoni* [nomen nudum] from man, cat, and dog; and heavy sparganum infections in frogs, snakes, and several mammals, from north, central, and south China. Sparganum larvae, indistinguishable as to species, were fed to various mammals including man. The sparganum from *Rana esculenta* gave infection in cat, not in man, and proved to be *D. mansoni;* that from *Microhyla sowerbyi* likewise gave infection in cat, not in man, and proved to be *D. decipiens;* that from *Canis procyonides* likewise infected cat, not man, and proved to be *D. ranarum;* that from *Erinaceus dealbatus* infected cat and dog, not rabbit or man, and proved to be *D. erinacei.* In no case was there indication that the parasite penetrated the intestinal wall or developed a somatic sparganosis. Sparganum larvae were found in man in 2 cases—an ulcerated thumb and an ulcerated wrist; both cases following the application of "split" frogs (presumably infected, as frog infestation is almost universal) to abscessed members as a therapeutic measure. To test the hypothesis that occurrence of sparganum infestation in the orbital region, or elsewhere in flesh or in adipose tissue, results from such application, sparganum larvae from the hedgehog were applied to the conjunctiva of a dog, and introduced aseptically into the thigh muscles of other susceptible animals. Infection apparently resulted; in some cases the parasites multiplied for several months.

7524. **FAUST, ERNEST CARROLL. A study of the rare human tapeworm, Taenia confusa, with a report of the fourth case.** *Southern Med. Jour.* 23(10): 902-906. 14 fig. 1930.—The entire living worm measured 495.5 cm. in length and consisted of 581 segments, an unsegmented length of about 5 mm. in the cervical region, and a scolex. The present study affords no new evidence as to the relationship of *T. confusa* and *T. bremneri* (Stephens), but the shape of the distal segments and the branching of the uteri in the 2 forms suggest that they are probably the same species. Moreover, the differences in length and breadth between the living and fixed examples of the terminal segments of the Louisiana specimen indicate that a marked variation in macroscopic appearance may obtain. A study of this latter material has shown that there is adequate evidence for retaining *T. confusa* as a separate species of the *T. saginata* type (subgenus *Taeniarhynchus*), in which the scolex is unarmed and in which the embryonic membrane is provided with polar projections.

7525. **FAUST, ERNEST CARROLL, and CLAUDE R. KELLOGG. Parasitic infections in the Foochow area, Fukien Province, China.** *Far East. Assoc. Trop. Med. Trans. 7th Congr.* 3: 268-278. 1927[1928].—The following important facts have been obtained from the survey of human parasitic infections: a small number of species and low incidence of intestinal protozoa; uniformly heavy infection with *Ascaris* and to a somewhat lesser degree of *Trichuris;* low (sub-clinical) incidence of hookworm infection in the area, except in the Hak Ka villages near Foochow, where a heavy infection of apparently pure *Ancylostoma duodenale* was encountered; absence of *Taenia, Echinococcus, Hymenolepis* and *Dipylidium* infection in the population; occasional presence of *Sparganum mansoni* in man and the possibility of human infection with the adult *Diphyllobothrium,* due to the high infectivity of the intermediate hosts commonly consumed as food without sufficient heating; incidental infection with *Schistosoma japonicum* and *Fasciolopsis buski* in the vicinity of Foochow; complete absence of *Clonorchis* infection in man and in dogs and its low percentage of infectivity in cats. It seems that human intestinal parasitic infections are not clinically so significant in northern Fukien as in the Yangtze Valley. Individuals may not infrequently manifest clinical symptoms due to infection with a particular species, and under certain local conditions a whole community may be seriously affected by a particular species; but the area as a whole is much less heavily parasitized than had been supposed. —*From authors' conclusions.*

7526. **FISCHER, WALTHER. Ein unbekannter Parasit der Leber.** *Virchow's Arch. Path. Anat. u. Physiol.* 269(1): 162-165. 3 fig. 1928.—Sections of a liver nodule showed a body which could not be identified as a foreign body, and which resembled no known parasite. The material, shown to several parasitologists, possibly represents one of the aberrant species of the Gastrotricha, common along the Baltic Sea.

7527. **GALIANO, E. FERNÁNDEZ. Los animales parasitos.** [Animal parasites.] 199p. 108 illus. Editorial Labor, S. A.: Barcelona & Buenos Aires, 1928.—In this small manual on parasitology the 1st section presents a general consideration of parasites, showing their various modes of adaptation, with brief morphological description, life history and mode of transmission. The remaining 3 sections are devoted to the description of arthropod, metazoan and protozoan parasites, with special reference to their life history, mode of transmission and the causation of disease in man. The book is especially recommended to pre-medical students.—*D. de Rivas.*

7528. **HAUGHWOUT, FRANK G. Note on the occurrence of "Sarcocystis" in the Philippine carabao (Bubalus bubalis Linn.).** *Philippine Islands Dept. Agric. and Nat. Resources Bur. Agric.* [*unnumbered pamphlet*] 8p. 1 pl. Manilla Bureau of Printing: Manilla, 1928.

7529. **HERRERA VEGAS, MARCELINO. Hydatid cysts of the lung in children.** 300p., 14 fig. S. A. Imprenta Lamb y Cia Ltd.: Buenos Aires, 1928.—A monographic study based upon exhaustive review of the literature and upon 50 cases under the care of the author, most of them operated by him. These cases occurred in a period of 20 years during which 25,000 children's histories were recorded. Each is reported in detail; there were 30 definite cures and 14 deaths. The volume treats of the life cycle of *Echinococcus granulosus,* the etiology and pathogeny of hydatid cysts, the pathological anatomy and symptoms of their formation, methods of examination, diagnosis, prognosis and treatment.—*H. W. Stunkard.*

7530. **HESS, WALTER N. Control of external fluke parasites on fish.** *Jour. Parasitol.* 16(3): 131-136. 1930.—Epidemics of external fish parasites of the genera *Ancyrocephalus, Dactylogyrus* and *Gyrodactylus* were successfully controlled by placing infected fish for 2 hrs. in large cement tanks containing 1 lb. $KMnO_4$ in 32000 gallons of water. The greater success of this method over the dip methods is attributed to longer exposure to a weaker solution. $KMnO_4$ was also very effective in controlling fluke epidemics on fish in open ponds. Since the chemical becomes ineffective due to oxidation in about 2 hrs. under such conditions, it does not permanently injure the fish. Hydrated lime was effective in killing those flukes and eggs left at the bottom of ponds after the ponds had been drained and the fish removed. Since the combined egg and larval stages of some of these flukes covered 9-18 days or longer, depending on weather conditions, the lime treatment was necessary following fluke epidemics if the ponds were

to be refilled and stocked with fry within the period referred to.—*W. N. Hess.*

7531. **HINDLE, EDWARD.** Further observations on Chinese kala azar. *Proc. Roy. Soc. London B* 103 (727): 599-619. 2 pl. 1928.—*Phlebotomus major* v. *chinensis* is the most favorable sp. for the development of *Leishmania.* The flagellates become attached to the lining of the mid-gut and grow forward until they reach the anterior part of the gut. Invasion of the pharynx usually takes 6 days, and under favorable conditions about 25% of the flies show a proboscis infection. *P. sergenti* is an equally favorable host for the early development, but the parasite remains confined to the broad posterior regions of the mid-gut, does not become attached to the lining of the gut, and never invades the proboscis. Infection depends on the presence of undigested food material and soon disappears when the gut is empty. Four out of 14 patients with kala azar gave positive results when sandflies were fed on them, but only about 5% of the flies became infected. Experiments with a large series of hamsters infected with Chinese kala azar show considerable variation (zero to practically 100%) in the proportion of sandflies showing development of flagellates after feeding on infected animals. In hamsters there is a marked correlation between the number of parasites in the skin and the proportion of flies becoming infected. No correlation was found between the presence of parasites in the circulating blood and infectivity to sandflies. A study of 5 human strains in hamsters showed the existence of varying degrees of virulence, ranging from a strain which was completely non-infective to sandflies, up to one highly infective both to hamsters and to sandflies. Both *P. major* v. *chinensis* and *P. sergenti,* infected with flagellates, gave negative results when fed on normal hamsters, and also when their contents were inoculated into the skin of hamsters. The intraperitoneal inoculation of the contents of 1 or more infected flies gave positive results in 7 out of 124 experiments with *P. major,* and 2 out of 41 with *P. sergenti.* There is evidence that Chinese kala azar may be congenitally transmitted, and also that a number of children recover from the disease without treatment.—*Author's summary.*

7532. **HOEPPLI, R.** Über Beziehungen zwischen degenerativen Gewebsveränderungen und Ausscheidungen parasitischer Nematoden. [Tissue degeneration and secretions of parasitic nematodes.] *Hamburg Univ. Abhandl. Gebiet Auslandsk.* 26: 177-183. 1927.—A review.

7533. **HOFFMANN, CARLOS C.** Über Onchocerca im Süden von Mexiko und die Weiterentwicklung ihrer Mikrofilarien in Eusimulium mooseri. *Arch. Schiffs- u. Tropen-Hyg.* 34 (9): 461-472. 5 fig., 1 map. 1930.—Hoffmann made a survey of onchocercosis in the southern part of the state of Chiapa. The infected regions are coffee-growing districts on the sierra slopes, about 400-1200 m. above sea-level, though isolated cases occur in the flat coast regions and on the mountains, presumably from migration of infected persons or insect carriers. On one plantation he found the characteristic nodules in 86% of the total population, microfilariae in the skin of the face and neck in 100%. Some nodules contained filariae of only 1 sex, and therefore no microfilariae. The microfilariae were found in the subcutaneous tissue in all parts of the body, but especially those exposed to the sun and air, like the cheeks and the nape of the neck. In many cases there were elephantiasis-like thickenings of the skin, especially of the ears; these, however, disappeared in part after operative removal of the nodules. Slight pain and transient disturbances of sight were present in a considerable number of cases, but Hoffmann saw no serious eye troubles and no blindness in those parts of Chiapa where the infection had existed for only 3-4 yrs. Blindness was observed only in neglected cases of at least 5-6 yrs. standing. The region was infested with 3 species of gnats, *Eusimulium ochraceum* Walker, the most abundant and universally distributed species, *E. mooseri* Dampf, which prefers shady places and forests, and *Simulium avidum,* a comparatively rare species, not obtained for study. Development of microfilariae after feeding on infected subjects was observed in *E. mooseri* but not in *E. ochraceum. S. avidum* is the only species of *Simulium* found in both of the Onchocerca-infected provinces of Mexico, Chiapa and Oaxaca. *Onchocerca volvulus* caecutiens (*O. c.*) (p. 471).

7534. [ЯКІМОV, V. L.] ЯКИМОВ, В. Л. К вопросу о паразитизме у пресноводных рыб. [Parasitism in fresh-water fishes.] Русский Журнал Тропической Медицины. [*Russ. Jour. Trop. Med.*] 6 (10): 649-651. 1 fig. 1928.—The author found trypanosomes in *Esox lucius* from lake Pid'mozero. He supposes leeches are the carriers.

7536. **IYENGAR, M. O. T., and PANCHANAN SUR.** Seasonal variations of the spleen-rate. *Indian Jour. Med. Res.* 17 (1): 11-32. 1929.—A single spleen census may lead to erroneous conclusions regarding the actual conditions of malarial endemicity of a locality because the spleen size, in areas so affected, shows seasonal variations. The spleen-rate is lowest during the dry season and greatest at the close of the wet season. The high level is reached Oct.-Jan. From Feb. the curve declines gradually, reaching the lowest level in June and July. In low endemic areas, there is also a spring rise in March and April. These findings are borne out by fever incidence records.—*E. M. Watson.*

7537. **JAMES, S. P.** A note on the Shute technique for staining malaria parasites with Leishman's stain and on the stippling in infected red blood corpuscles which it reveals. *Trans. Roy. Soc. Trop. Med. and Hyg.* 23 (3): 269-278. 1 fig. 1929.—A new and unfailing technique for staining blood cells is described in detail which demonstrates an unnamed type of stippling in the erythrocytes infected with *Plasmodium malariae* and the presence of Schüffner's dots and Maurer's spots in corpuscles infected with *P. vivax* and *P. falciparum* in younger stages than with the older Leishman's stain.—*M. W. Kamm.*

7538. **JAMOT, E.** La maladie du sommeil au Cameroun. *Rev. Prat. Malad. Pays Chauds* 9 (7): 326-337. 1929.—After diagnosis has been made all patients receive 5 or 6 injections of atoxyl. Some months later they are given 10 injections with tryparsamide. Jamot confirms the findings of others that the latter is the only drug which influences the trypanosomes in the central nervous system. By these methods the annual mortality has been reduced from 50 to 6%, the number of organisms, and hence the danger of transmitting the disease has been lessened, and the birth rate has risen.—*R. W. Linton.*

7539. **JOHNSON, THURSTON L.** In vivo trypanolysis with special reference to zones of inhibition, relapse phenomena and immunological specificity. *Amer. Jour. Hyg.* 9 (2): 260-282. 1929.—Suitable doses of specific antisera injected intraperitoneally into mice infected with *Trypanosoma equinum, T. brucei* and *T. equiperdum* resulted in trypanolysis and delayed death. In the *T. equinum* and *T. brucei* series, graded dosage of the sera resulted in a zone phenomenon, which occurred, however, only with blood infections of certain intensities. Relapse strains were susceptible in a small number of cases to the lytic action of a 2nd dose of serum. In such cases the zonal effect occurred during degrees of infection differing from those necessary to produce the phenomenon in the original infections. The action of antisera was not specific for the homologous strain.—*L. J. Davis.*

7540. **JOHNSON, THURSTON, L.** The non-occurrence of the zone phenomenon in the curative action of drugs and normal human serum in Trypanosoma equinum infection. *Amer. Jour. Hyg.* 9 (2): 283-291. 1929.—The administration of trypanolytic drugs and of normal human serum in graded doses to mice infected with *T. equinum* failed to produce a zonal effect. All doses above the effective minimum destroyed the trypanosomes.—*L. J. Davis.*

7541. **KAMISAKA, T.** How to differentiate between

the eggs of Fasciola hepatica and Fasciolopsis buski. *Taiwan Igakki Zasshi* [*Jour. Med. Assoc. Formosa*] 308. 71. 1930.—In *F. hepatica* the granules in the yolk cells accumulate around the nuclei; in *F. buski* they are equally distributed throughout the cell.—*E. C. Faust.*

7542. [KAZAKOV, P. T.] КАЗАКОВ, П. Т. К вопросу о распространении Hymenolepis nana в Ленинграде. [Hymenolepis nana in Leningrad.] [German summary.] Русский Журнал Тропической Медицины. [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 6(9): 588-597. 1928.—*H. nana* was found in 0.3% of cases. Invasion has increased since 1923. All ages and sexes are affected. Hemograms showed that *H. nana* chronically poisons the organism with hemolytic toxins. The author observed decrease of erythrocytes and hemoglobin, lymphocytosis, monocytosis, eosinophilia, and deviation of the leucocytic formula to the left.

7543. KOBAYASHI, HIDEKAZU. Studies on the development of Diphyllobothrium mansoni Cobbold, 1882 (Joyeux, 1928). II. On the conditions of development of the eggs of Diphyllobothrium mansoni. *Taiwan Igakki Zasshi* [*Jour. Med. Assoc. Formosa*] 307. 61-62. 1930.—The author studied the influence of temp., chemicals, light, bacteria, toxicity and humidity on the development of the eggs.—*E. C. Faust.*

7544. KORKE, VISHNU T. The relation of ankylostome infestation to the physical features of an agricultural area in India and to the social and economic status of its population. *Far East. Assoc. Trop. Med. Trans. 7 Congr.* 3: 249-257. 1 map. 1927[1928].—There is correlation between the agricultural and economic conditions and the hookworm prevalence among the agricultural class in the Gaya district. The value of the correlation assumes a diagnostic significance. Moisture plays an important rôle in determining the hookworm conditions of an area. A mean degree of infection by 20 hookworms per person (or 2,000 ova per gm. of feces) would represent one unit of moisture; or fertility of the soil of the first degree (Grierson-Moore classification). The mean degree of hookworm infestation among persons residing on a sloped surface was less by half than that of a level surface. Under circumstances where establishment of a proper conservancy system is impracticable and where promiscuous defecation unaided by conservancy has to be accepted, as is for the present inevitable, the agricultural population may be encouraged to defecate on a dry sloped surface.—*Author's conclusions.*

7545. KORKE, VISHNU T. The correlation between ankylostome disease and haemoglobin value as obtained in regard to the physical features of an agricultural area in India and to the social and economic status of its population. *Far East. Assoc. Trop. Med. Trans. 7th Congr.* 3: 258-264. 1927[1928].—The predisposing factor of the ancylostome disease is in direct relation to the physical features of an agricultural area and to the social and economic status of its population, these conditions expressing the degree of resistance of the groups to the disease. The group resistance is expressed in the terms of mean Hb value, which is in direct relation to the economic condition prevailing in an agricultural area. A comparatively small degree of mean hookworm infestation sufficed to bring on the disease in a group whose resistance had been lowered by economic conditions. In the groups of agricultural population the landless labour class was first to succumb. There was no direct correlation between the mean degree of hookworm infestation and the disease in the agricultural groups of population except through the medium of the agricultural features and the social and economic status of its population.—*Author's conclusions.*

7546. KORKE, VISHNU T. Prevalence of filariasis in some areas in British India. *Far East. Assoc. Trop. Med. Trans. 7th Congr.* 3: 304-310. 1927[1928].—There is a considerable prevalence of filariasis in the different groups of population in Bihar and Orissa. 14% of cases showed microfilariae in the peripheral blood where filariasis was suspected on clinical grounds, and 6% where not suspected. The microfilariae were detected most readily during the night; 11% of cases showed them during the day. The notable clinical features were affections of the glands (chiefly inguinal) and the genitals. The predominant species was *Microfilaria bancrofti.*

7547. KRIJGSMAN, B. J. Biologische onderzoekingen aan het systeem: gastheer-parasiet. Deel 1: De ontwikkeling van Trypanosoma evansi in de muis. [Biological investigations on the host-parasite system. 1. Development of T. evansi in the mouse.] *Ned.-Indische Bladen Diergenecsk.* 42(6): 499-563. 1930.—This study comprises the first part of a proposed systematic study of *T. evansi* in different species of mammals. After carefully standardizing such technical methods as the isolation of single-cell strains, procuring a standard mouse by special feeding, counting trypanosomes in different inocula and making various statistical determinations on the parasites during infection, the author amassed a large amount of pertinent data. Detailed studies were made of the parasites and their curves of development throughout the course of infections. The relation of these data to the mode of infection and the number of parasites used to start the infection was also investigated. Among the conclusions drawn the following are of particular interest: Death is associated with a constant number of parasites in the blood. Various types of data are obtained indicating that the velocity of growth of the trypanosomes is typically rhythmical. The increase in numbers taken over the entire infection does not follow a geometrical progression, although for a portion of the time during the highest velocity of multiplication it does. Degenerative forms appear toward the end of the infection and parasites without blepharoplasts [parabasal bodies] are always present in varying numbers. Up to a certain point development of the parasites in the blood resembles the growth of bacteria in artificial media. The author believes that the development of *T. evansi* in the mouse is largely a problem of metabolism.—*W. H. Taliaferro.*

7548. LABERNADIE, V. G. F. Documents statistiques sur les helminthiases à Pondichéry. [Statistical data on the helminths of Pondichéry, French India.] *Far East. Assoc. Trop. Med. Trans. 7th Congr.* 3: 198-199. 1927 [1928].

7549. LEVIN, A. L. The problem of eradication of Strongyloides intestinalis. *Amer. Jour. Trop. Med.* 10 (5): 353-363. 1930.—A fair number of individuals in Louisiana and Mississippi, and most probably in other southern states, have an infection. No age is immune. Infection is prevalent among males, with greater preponderance among whites. There is definite evidence of a mild anemia and eosinophilia. Nearly all cases presented symptoms of a gastrointestinal disturbance with a fair background of a biliary toxemia. Gastric acidity ranges from achylia to a mild hyperchlorhydria. Severe infections only can produce diarrhea and colic; the average patient is constipated. Infection can be present in the human intestinal tract for many years; ordinary infection does not undermine human health. No form of treatment has any permanent value. A drug, by the intra-venous route, may probably lead to permanent eradication.—*Author's summary.*

7550. LEWIS, E. ANEURIN. An account of a survey of the parasitic helminths of some domestic animals in Mid-West Wales. *Jour. Helminthol.* 8(1): 1-18. 1930.—Gives tables showing the helminthic infection of sheep in the Aeron, Valley and Borth districts, the variation of the infection in those districts, the annual helminthic infection in the whole area, the number of parasites collected from individuals, and the seasonal incidence of cestodes. For sheep are recorded: *Monodontus trigonocephalus, Nematodirus filicollis, Trichostrongylus vitrinus, Cooperia oncophora, Trichuris ovis, Oesophagostomum venulosum, Chabertia ovina, Ostertagia circumcincta, O. trifurcata, Haemonchus contortus, Dictyocaulus filaria. Muellerius capillaris. Protostrongylus rufescens, Capillaria longipes, Moniezia* spp., *Cysticercus tenuicollis, Echinococcus* sp., *Coenurus cerebralis, Fasciola hepatica.* From cattle: *Fasciola hepatica, Moniezia*

spp., *Capillaria* spp., *Monodontus phlebotomus, Dictyocaulus viviparus.* From pigs: *Ascaris lumbricoides, Trichuris suis, Oesophagostomum dentatum, Metastrongylus elongatus, M. brevivaginosus* (Gedoelst, 1927), *Cysticercus tenuicollis, Fasciola hepatica.* From chickens: *Heterakis vesicularis, Capillaria* spp., *Ascaridea lineata, Syngamus trachea, Davainea proglottina.* From ducks: *Capillaria anatis, Polymorphus minutus, Echinocotyle rosseteri, Porrocoecum crassum.* From geese: *Heterakis dispar, Capillaria* spp. From pheasants: *Syngamus trachea, Heterakis vesicularis, Capillaria* spp. From guinea-fowls: *Heterakis brevispiculosum, Capillaria* spp. In each case observations on the frequency and periodicity of the parasite are given.—*F. J. Meggitt.*

7551. **McCOY, O. R. Experimental studies on two fish trematodes of the genus Hamacreadium (family Allocreadiidae).** *Jour. Parasitol.* 17(1): 1-13. 2 fig. 1930.—The life history of *Hamacreadium gulella** Linton, a parasite of the gray snapper, *Lutianus griseus,* was found to parallel exactly that of *H. mutabile* Linton, also parasitic in the gray snapper. Both cercariae are of the cotylocercous type, occur in the same snail host. *Astraea americana,* and encyst in various small fish. The bluehead, *Thalassoma bifasciatum,* and slippery dick, *Halichoeres bivittatus,* are apparently the natural second intermediate hosts. In cross-infection experiments both *H. mutabile* and *H. gulella* developed only in fish of the snapper family, Lutianidae, and failed to develop in numerous other species tested. A method is described for administering approximately equal doses of cysts to a series of fish and studying infections quantitatively. Cysts were not infective on the 1st or 2nd day after the cercariae had penetrated the fish; about ½ were infective on the 3rd day and all on the 4th. The infectivity did not increase or diminish for cysts up to 12 days of age. A heavy previous infection of snappers with either *H. mutabile* or *H. gulella* did not confer any very appreciable resistance against a 2nd infection. There is evidence, however, that with *H. gulella* the 2nd infestation in previously infested fish was not quite so great as in control fish. Snappers given an infestation of several hundred *H. gulella* lost practically all of the worms within 4 weeks. In a single experiment fish given only a light dose of cysts, 10-15, did not lose the worms. The rapid and in many instances complete loss of worms in heavily infested fish is apparently caused by some reaction of the fish against the parasite.—*Author's summary.*

7552. **MAGARINOS TORRES, C., e E. LIBANIO VILLELA. Nematodios immaturos, parasitos erraticos e desgarrados encontrados nos tecidos do homem. [Immature nematodes as unusual and accidental parasites in human tissues.]** *Mem. Inst. Oswaldo Cruz* 22: 161-167. 8 pl. 1929.—Larval forms of *Agamofilaria* (sp.?) from fibroid cysts on the the visceral peritoneum; larval forms of an unknown nematode (*Agamonematodum?*) from epididymal cysts; unrecognizable larval fragments from cysts in the uterine mucosa; and encapsulated eggs, possibly of *Ascaris lumbricoides,* were recognized during routine histological examination of post mortem tissues and are ascribed to abnormal migrations of the parasitic larvae or of eggs of such parasites.—*A. C. Walton.*

7553. **MELLO, FROILANO de. Etudes sur le sang de Manis pentadactyla, L.** *Arquivos Escola Med.-Cir. Nova Goa. Ser. A.* 1929(4): 512-516. 1929.—From the blood of the pangolin, commonly known as the goanese tyrio, *Plasmodium* tyrio is described. There were encountered also endoglobular bartonelliform elements intermediate between *Grahamella* and *Paraplasma;* the parasitic nature of these bodies is considered doubtful.—*M. F. Boyd.*

7554. **MIYAMOTO, TOSINOBU. Strongyloidosis intestinalis in the farrow of Formosa.** *Far East. Assoc. Trop. Med. Trans. 7th Cong.* 3: 686-698. 1927[1928].—The disease, locally known as "white diarrhoea," is extensively prevalent, but of a latent chronic character. Primarily, it arrests the development of innumerable young pigs, causing their death; the loss exceeds that from acute infectious diseases. Secondarily, it impairs resistance to other infectious diseases or to the ill effects of bad environment.

7555. **MORGAN, D. O. The helminth parasites of the goat in Britain, including an account of Skrjabinema ovis (Skrjabin, 1915) Werestchagin, 1926.** *Jour. Helminthol.* 8(2): 69-76. 6 fig. 1930.—Records *Cysticercus tenuicollis, Moniezia expansa; Muellerius capillaris* and *Dictyocaulus filaria* (lung), *Haemonchus contortus, Ostertagia circumcincta, O. trifurcata, Trichostrongylus extenuatus* (abomasum); *Trichostrongylus colubriformis, T. vitrinus, T. capricola, Capillaria longipes, Cooperia curticei, Nematodirus filicollis* (small intestine); *Oesophagostomum venulosum, Chabertia ovina, Trichuris ovis* (caecum and large intestine).—*F. J. Meggitt.*

7556. **O'ROKE, EARL C. The morphology, transmission, and life-history of Haemoproteus lophortyx O'Roke, a blood parasite of the California valley quail.** *Univ. California Publ. Zool.* 36(1): 1-50. 2 pl., 6 fig. 1930.—*Haemoproteus* **lophortyx** (p. 8) is transmitted by *Lynchia hirsuta* Ferris, a louse fly (Hippoboscidae). Oöcysts and sporozoites were found in flies taken on infected quail; attempts to transmit the parasite by the bite of flies failed owing to the small number of flies available. One case of transmission was accomplished by injecting sporozoites from an infected fly into the blood of a quail. Transmission was also effected by transplanting a lung of an infected quail into the body cavity of a susceptible quail. Sporozoites were found in oöcysts on the mid-gut, among the tissues of the haemocoele, and in the salivary glands of infected flies. Schizonts were found in the lungs, liver, and spleen of parasitized birds. Merozoites were found in endothelial cells of capillaries of the lungs, in epithelial cells of the liver, and, on rare occasions in acute cases, in the peripheral blood. Gametocytes were found in the red blood cells. Gametogenesis occurred on the microscope slide at room temp. In microgametogenesis, the gametes are fully formed inside the gametocyte and escape through rupture of the cell membrane. The microgamete is definitely polarized with its nucleus toward the anterior end. Development of the macrogametes is associated with the formation of 2 polar cells. Fertilization is accomplished in 15 seconds, the entire microgamete entering the macrogamete. A fertilization membrane appears to be formed immediately after the penetration of the microgamete. The zygote elongates into an oökinete on the slide. On one occasion an oökinete was observed to penetrate the wall of the gut of a fly. The effects on the host vary from infections which appear to be benign to those which are fatal.—*From author's summary.*

7557. **[PANOV, A. A.] ПАНОВ, А. А. Пораженность детей г. Мариуполи острицей (Enterobius vermicularis L. 1767) и сравнительная ценность методов употреблявшихся при обследовании на оксиуру. [E. vermicularis in children of Mariupol.]** [German summary.] Русский Журнал Тропической Медицины. [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 6(8): 525-528. 1928.—Perianal and subungual grattage of 319 children, aged 10-16, showed that 80.2% were positive for *E. vermicularis.*

7558. **PEARSE, A. S. The internal parasites of Nigerian rodents and insectivores.** *Jour. Elisha Mitchell Sci. Soc.* 45(2): 221-238. 1930.—The parasites of 29 species of small mammals were studied. Protozoa and strongylid nematodes were rare in insectivores, and cestode cysts were less common than in rodents; but tapeworms and types of nematodes which usually enter the host through the mouth with the food, rather than through the skin, were much more frequent. On the whole, parasites became fewer toward the desert as the climate grew dryer. This was largely due to the decrease in nematodes. The rodent which may be expected to have most parasites is large, eats both insect and plant foods, and lives on the ground among luxuriant vegetation in a climate which is not too wet or too dry.—*A. S. Pearse.*

7559. **PRITZE, FELIX. Beiträge zur Kenntnis des**

Balantidium coli. Das Balantidium des Schweines in seiner Beziehung zum menschlichen Balantidium und sein Verhalten unter natürlichen und künstlichen Bedingungen. *Zeitschr. Wiss. Biol. Abt. F, Parasitenk.* 1(3): 345-415. 47 fig. 1928.—A comprehensive account of occurrence, morphology, and reproduction, and of cultivation and infection experiments. Bode's "budding" is an involution phenomenon. No morphological differences in *Balantidium* can be established on the basis of occurrence alone; diversities in serological relations probably indicate different species. Of 400 swine examined, 67% showed *Balantidium*, 28.25% vegetative forms; the feces are formed, soft and mostly of undigested plant residue; the pH relations of the host feces give indication as to the presence of *Balantidium*, the optimum being about 6.4. Swine embryos do not carry *Balantidium*. Throughout encystment there is rapid rotation within the cyst; at the close of encystment the cilia apparently are resorbed; when much dried, appearances resembling plasmolysis are seen in the cysts. *B. coli* divides amitotically; the nuclear structure is not uniform and depends upon age. The fission rhythm seems dependent upon the activity of the host. Infection by mouth seems to occur only through cysts; vegetative forms can probably be carried over through the year; duration of life of *B. coli* is longer at 15° than at 38°. *B. coli* seems to be strongly anaerobic; the pH of the culture is indicative of the vitality of the parasite. In amniotic fluid at room temp. a maximum duration of life of 474 hrs. was observed.—*M. M. Metcalf.*

7560. **RUGE, REINHOLD.** Ein Beitrag zur Schwarzwasserfieber-Frage. *Arch. Schiffs- u. Tropen-Hyg.* 33(6): 328-330. 1929.—There are different strains of malignant malarial parasites (*Plasmodium falciparum*). The West African strain differs morphologically and ecologically from those in other parts of the world. It exerts greater hemolytic action and is often associated with blackwater fever.—*A. S. Pearse.*

7561. **SCHACHSUWARLY, M.** Über die Beeinflussung von Entamoeba histolytica in der Kultur durch die Konzentration des Mediums und durch Bakteriophagen. *Arch. Schiffs- u. Tropen-Hyg.* 33(3): 129-134. 1929.—Rapid raising or lowering of the NaCl content does not lead to encystment of *Entamoeba histolytica;* the lowest concentration for growth is 0.05% and the highest 1.5% for fluid media; the high concentration of salt increases the density of the endoplasm and a more coli-like habit in the organisms. Shiga-Kruse bacteriophage inhibits growth, while Flexner, Y and coli lysates are without effect.—*D. H. Bergey.*

7562. **[SCRĬABIN, K. I., and S. SCHULTZ.]** СКРЯБИН, К. И., и С. ШУЛЬЦ. Гельминтозы человека. [Helminth diseases of man.] 376p. 111 fig. Государственное Медицинское Издательство. (State Medical Publishing Society, Moscow) 1929.—This book is designed primarily for physicians and medical students, but also includes chapters on anatomy, biology, systematics and distribution of helminths which may prove of interest to the scientist. The 1st part deals with the rôle of helminths in pathology, and treats of trematodes and cestodes, with an anatomo-biological description of the diseases which they produce. The 2nd part deals with nematodes and the diseases caused by them, and, as a whole, with the elements of general medical helminthology. An extensive bibliography is given.

7563. **[SINEL'NIKOV, A. M.]** СИНЕЛЬНИКОВ, А. М. Гельминтологическое обследование железнодорожных школ г. Ашхабада. [Helminthological examinations in the railroad schools of Ashkhabad.] Русский Журнал Тропической Медицины. [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 6(10): 652-654. 1928.—Out of 332 boys, 24.42% were positive for worms; out of 390 girls, 29.02%. Infestation with *Hymenolepis nana* and *Trichuris trichiura* predominated; 2 cases of *Ancylostoma duodenale* and 2 of *Necator americanus* were observed.

7565. **SWEET, W. C.** Notes on a quantitative hookworm survey of Ceylon. *Far East. Assoc. Trop. Med. Trans. 7th Congr.* 3: 237-248. 1927[1928].—About 90% of the population is infected, the incidence being somewhat higher in the dry zone where tanks and irrigation are common and rainfall is confined to a short period. The wet zone has had 10 years of hookworm control work which may have resulted in the lower rates, but frequent and heavy rains may also be a deterrent. Quantitative estimations showed that the average Ceylonese had an intensity rate of only 2,200 eggs per gm. "basis formed faeces," approximately 100 hookworms. The long dry season of the north, the excessive rainfall of parts of the south, and the hookworm control work were possibly responsible for this, in varying proportions. The average egg-counts per gm. of the children from 7 to 14 yrs. were numerically equal to those found among adults, making it possible to estimate adult averages by examining school children, where no control work had voided the relationship. A study of the distribution of the infection in the population of 2 provinces in which the average rate was 2,800 eggs per gm. showed that but 53% of the people had what Smillie classified as hookworm disease, the remainder being merely carriers. The relatively high infection in the children, the habits and customs of the people, the fact that night-soil was not appreciably used as fertilizer, and the general lack of latrines, made it seem clear that the infection was acquired from pollution around the living quarters. Against this fact was the relatively high intensity of infection among adult males engaged in rice cultivation, about 35% higher than that of the surrounding peoples.—*From author's conclusions.*

7566. **THAPAR, GOVIND SINGH.** Preliminary observations on ankylostomiasis in pariah dogs. *Far East. Assoc. Trop. Med. Trans. 7th Congr.* 3: 265-267. 1927 [1928].—Note on the finding of *Ancylostoma duodenale* in the intestines of dogs in Lucknow.

7567. **[VASICH, E. A.]** ВАСИЧ, Е. А. Случай диспепсии у грудного ребенка на почве аскаридоза матери. [A case of infant dyspepsia due to ascaridiasis in the mother.] Русский Журнал Тропической Медицины. [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 6(9): 603. 1928.—The mother was apparently healthy, yet the child's dyspepsia continued for 2½ mo. and ceased only upon complete removal of ascarids from the mother.

7568. **VOLKMAR, FRITZ.** Capillariasis vesico-urethralis of silver foxes. *Vet. Med.* 25(12): 518-520. 1 fig. 1930.—*Capillaria plica* in silver foxes in N. Dakota and *Trichosomoides crassicauda* in the common rat are reported. The eggs (including both plugs) of *C. plica* measure 63-65 × 27-28 μ in fresh material and 58 × 32 μ after being embedded for 6 months.—*F. Volkmar.*

7569. **YOKOGAWA, SADAMU.** Results of comparative studies on oral and cutaneous infection of dogs with Ancylostoma caninum. *Hamburg Univ. Abhandl. Gebiet Austlandsk.* 26: 608-611. 1927.—See *Trans. Japanese Path. Soc.* 17: 218-224. 1927.

7570. **ZUCCARINI, J. A.** Estudio experimental sobre el "Trypanosoma cruzi." *Rev. Soc. Argentina Biol.* 6(4): 217-224. 1930.—Two human strains and 2 from *Triatoma* kept in mice were studied. In mice 1-5 days old infection is constant, incubation period 36 hrs.—5 days, death in 11-18 days. Trypanosomes in blood increase to 50-60 per field. Virulence as tested by inoculation in adults is not influenced by passage through young animals. In the heart, leishmaniaform nodules were found. Rabbits were infected 5-12 hrs. after birth, dying in 20 days. Six guinea-pigs were inoculated just after birth; 3 were infected, the disease following the same course as in adults. In mammals infection is more severe in the young.—*J. T. Lewis.*

FILTERABLE VIRUSES, BACTERIOPHAGE, ETC.

7571. ASHESHOV, IGOR N., Mrs. I. ASHESHOV, SARANJAM KHAN, and M. N. LAHIRI. Bacteriophage inquiry. Report on the work during the period from 1st January to 1st September, 1929. With appendix. Report on the treatment of cholera. *Indian Jour. Med. Res.* 17(3): 971-984. 1 pl. 1930.—Three types, A, B, and C, of cholera bacteriophage have been differentiated upon the basis that the secondary growth of the cholera vibrio, although resistant to the particular bacteriophage used, is still susceptible to the other types. Thus, secondary growth of A is susceptible to B or C; resistant growth of B, to A or C, and so on. Unknown types or mixtures of bacteriophage can be determined by testing against standard strains. Biologically, Type A is a quick-acting bacteriophage producing complete lysis within 2 hrs.; the majority of races of this type lose their virulence in a few days. Type B is less active and lysis is seldom produced in less than in 3 hrs.; this type is more stable and may be kept for several mo. Type C is slow-growing; lysis is rarely complete but the vibrio may be killed without visible lysis. Type A attacks the S variety only, but B and C attack both the S and R forms of the bacterium. For treatment, it is essential that the preparation be polyvalent, preferably with an excess of Type A, as it is imperative to destroy the vibrio as soon as possible. The value of the treatment has not been ascertained, but the fact that a bacteriophage producing complete and permanent lysis in a test-tube in less than 2 hrs. can not reach all the vibrios in the body and destroy them in less than 6 hrs., during which time the patient is being continuously poisoned, has led the authors to defer conclusion until further study. It does, however, arrest progress of the disease and shorten its course considerably, if given together with intravenous saline infusion. Further, it is believed to be effective for prophylaxis when the bacteriophage is distributed in wells during epidemic seasons.— *F. F. Tang.*

7572. BORREL, A. Die Ätiologie der bösartigen Geschwülste. *Zeitschr. Krebsforsch* 32(6): 646-671. 1 fig. 1930.—The author has long been a proponent of the infectious theory of cancer, and in this article he maintains the same attitude. His arguments may be briefly summarized as follows: the causation of malignant disease by the several definitely known cancerogenic parasites is best explained by assuming that they act as carriers of a specific virus, inasmuch as at best their cancerogenic action is capricious in character; the susceptibility of certain tissues he interprets as the result of excessive liability to infection with a virus; the phenomena of the Rous virus are best explained by the parasitic hypothesis. The paper presents a detailed description of the method of cover-glass preparations of tissue cultures, suited for detailed staining methods.— *H. E. Eggers.*

7573. EAGLES, G. H., and D. McCLEAN. Cultivation of vaccinia virus in a cell-free medium. *British Jour. Exp. Path.* 12: 97-102. 1931.—A neurotesticular virus was successfully cultivated in series in a mixture of kidney extract and Tyrode's solution, with or without serum. Kidney extract was made by mincing sterile rabbit kidney in Tyrode's solution and centrifuging at high speed for 20 min. The supernatant fluid is the extract, and examination in hanging-drop and smear preparations shows it to be cell-free. To be sure that a cell-free medium was used, some experiments were done in which the extract was filtered through Chamberland L_2 candles. Cultivation was successful in this medium also.—*J. Bland.*

7574. GLASER, ERHARD. Das Wesen des bakteriophagen Princips als Grundlage der pharmakognostischen Beurteilung. *Pharmaceut. Monatshefte* 11(9): 187-200; (10): 226-228; (11): 250-254. 1930.—More information concerning the nature of the bacteriophage principle is necessary to allow its evaluation in scientific medicine. From a review of available facts and statements, the author concludes that most investigators have turned away from the "living nature" view of d'Herelle and regard bacteriophagy as an enzymatic reaction. An extensive bibliography is appended.—*E. Glaser* (*transl. by J. B. Nelson*).

7575. GRAHAM, J. D. Recherches sur le bactériophage dans l'Inde Britannique. *Office Internat. Hyg. Publ.: Bull. Mensuel* [*Paris*] 22(10): 1882-1892. 1930.—This paper incorporates the reports of several workers. I. Studies made at Patna under the direction of IGOR ASHESHOV in collaboration with SARANJAM KHAN and M. N. LAHIRI. (See this issue, Entry 7571.) II. J. TAYLOR. Bacteriophage in cholera and dysentery. In 33 cholera cases (19 controls and 14 treated with bacteriophage), mortality was 53% for controls and 57% for treated cases. In 46 cases of bacillary dysentery (26 treated and 20 controls), 34 Shiga and 12 Flexner types, there were 2 deaths from dysentery among controls and 2 among treated patients. Taylor concludes that in neither cholera nor dysentery does bacteriophage influence the course. III. J. MORISON. Bacteriophage of cholera and dysentery. Report of 3 epidemics. IV. Bacteriophage of cholera. An investigation by R. H. MALONE into well-waters and flies in 33 Pendjab villages showed the presence of a virulent cholera bacteriophage in the flies or well-water, or both, of 13 of 24 villages when there was no cholera epidemic in 1927 or 1928; in 1 of 3 villages where cholera raged in 1927 but not in 1928; in 1 of 4 villages where there was cholera in 1928 but not in 1927; and in 1 of 2 villages where cholera broke out in 1927 and 1928. V. Investigation into cholera bacteriophage in well-water. In none of 8 villages (in 4 of which cholera had just broken out) was cholera bacteriophage found in the well-water by IYENGAR.

7576. GRUMBACH, A. Ueber Streptokokkenbakteriophagen und Dissoziationserscheinungen an Streptokokken. *Zentralbl. Bakt. I. Abt. Orig.* 118(3/4): 206-216. 24 fig. 1930.—Low magnification of isolated colonies of streptococci showed that more than 60% were flat types, and more than 80% variant types. Most of the streptococcus variants were apparently associated with a bacteriophage. The failure to ferment esculin, and to reduce litmus milk, and the presence of the hemolytic reaction with enterococcus, appeared to be related to the presence of bacteriophage.—*Author's summary* (*transl. by J. B. Nelson*).

7577. HELLERSTROM, S., et E. WASSEN. Étude du virus de la lymphogranulomatose inguinale. *Compt. Rend. Soc. Biol.* 106(10): 802-803. 1931.—A preliminary report. Human and animal material preserved in glycerin loses its virulence after 7 days. Positive results were obtained once (with 4 strains) after passing ganglionic substance through a Berkefeld filter.—*E. Weiner.*

7578. HOLST, PETER. L'encéphalite post-vaccinale en Norvège. *Office Internat. Hyg. Publ.: Bull. Mensuel* [*Paris*] 22(6): 1132-1147. 1 map. 1930.—From 1921 to 1929, 28 cases (15 fatal) of postvaccinal encephalitis, always occurring after a typical incubation period, have been observed in Norway. The author argues against identification of postvaccinal encephalitis (which occurs in summer and seldom in persons over 10 yrs. old) with either lethargic encephalitis (a typical winter disease) or poliomyelitis (an autumnal disease affecting adults as well as children). While the author emphasizes the causal connection of vaccination with this disease, he does not believe that encephalitis virus is contained in the vaccine, because in the Netherlands the imported

Danish vaccine causes as many cases of encephalitis as the Dutch vaccine, although no case of encephalitis has yet been observed in Denmark. He suggests that vaccination may stir into activity a latent virus.

7579. **HORMAECHE, ESTENIO, y FRANCK HUGHES.** Sobre la autolisis "in vitro" del bacilo de Koch. [In vitro autolysis of tubercle bacilli.] *Rev. Tuberc. Uruguay* 1(1): 47-51. 1930.—Shortly after the appearance of the first colonies on egg media planted with human material, a complete lysis of the whole culture sometimes occurs, leading to complete disintegration of the organisms, neither modified bacterial forms nor granules appearing. Washings of these autolyzed, sterile cultures failed to cause either typical or "filterable virus" tuberculous lesions in guinea pigs, thus proving a destruction of the bacilli differing from that associated with bacteriophagic actions.—*A. de Assis.*

7580. **HURST, E. W., and R. W. FAIRBROTHER.** Simultaneous infection of the monkey with the viruses of poliomyelitis and vaccinia. *British Jour. Exp. Path.* 12: 17-20. 1931.—In the monkey, infection with a highly virulent neurovaccine apparently has no power to modify the nerve lesions of poliomyelitis; this is equally true whether the vaccine is injected directly into the brain or inoculated intradermally. If both viruses are administered intravenously, the resulting vaccinal reaction does not suffice to permit invasion of the nervous system by poliomyelitis virus. It was impossible to demonstrate an activation effect of vaccinia on a weak poliomyelitis virus. It seems unlikely that, if postvaccinal encephalitis is due to the activation of a latent neurotropic virus by vaccination, any virus hitherto isolated and studied is responsible for the nervous disease.—*J. Bland.*

7581. **LEVADITI, C., et P. LÉPINE, (with collaboration of Mlle. SCHOEN).** L'encéphalite herpétique expérimentale du singe. *Acta Med. Scandinavica* 71 (1/2): 192-220. 2 col. pl. 1929.—In 66% of the animals inoculated, lesions of herpetic encephalitis were produced in monkeys (*Cercopithecus callithrix*) by multiple inoculations. The disease, in its chronic form, preserved a clinical picture comparable to that in human encephalitis. Infected brains of monkeys dead from herpetic encephalitis were virulent for rabbits. Varying types of microscopic lesions were found—some being characteristic of encephalitis in man; some, of the disease in rabbits. Frequently, lesions of both an acute and chronic nature were coexistent. This monkey can be used for study of human epidemic encephalitis.—*A. M. Woodruff.*

7582. **LEWTHWAITE, RAYMOND.** Experimental tropical typhus in laboratory animals. *Bull. Inst. Med. Res. Federated Malay States* 1930(3): (1-10). 1930.—Blood from patients and from organs of fatal cases of tropical typhus were injected into guinea pigs or rats, mostly by the intraperitoneal route. Guinea pigs gave rarely a febrile reaction; histologically, the brain showed inflammatory changes; the Weil-Felix was negative; and there was no scrotal reaction. Rats more frequently gave a rise in temp. Postmortems revealed pulmonary and lymphatic lesions, and a slight enlargement of the spleen. Histologically, lesions of the brain were noted. Typhus exanthematicus and tabardillo fever are certainly different from tropical typhus.—*E. Lagrange (transl.).*

7583. **McCLEAN, D., and G. H. EAGLES.** The conservation of vaccinia virus grown in vitro. *British Jour. Exp. Path.* 12: 103-107. 1931.—Tests were made with various types and strains of vaccinia virus. The protective effects of cysteine hydrochloride, glycerine, agar, gelatine, borax buffer solution, fresh minced tissue, Hartley's broth and "hormone" broth were studied. Tests were done at room temp., in the cold room, and frozen. The effect of oxidation and of anaerobiosis were also studied. Glycerine has little effect in conserving the virus, whether from culture or animal passage. No satisfactory way was found to preserve virus cultivated in the chick-embryo and plasma medium of Carrel and Rivers. Phenol (1%) may be used to free culture virus from bacterial contaminants without bad effect on the virus over long periods of storage, provided the medium is not frozen. Virus cultivated in the unfiltered, cell-free kidney extract survives without great loss of titer under anaerobic conditions in the cold room. Virus cultivated in Maitland's kidney medium survives still better. Filtered kidney extract is a less satisfactory medium than is the unfiltered, for preserving vaccinia culture virus.—*J. Bland.*

7584. **MARCANDIER, PLAZY, Le CHUITON, et R. PIROT.** Transmission au singe de la fièvre exanthématique observée à bord des navires de guerre à Toulon. Ses rapports avec le typhus exanthématique. *Bull. Acad. Méd. [Paris]* 105(24): 1012-1015. 1931.—In 3 of 4 monkeys intraperitoneally inoculated with blood from shipboard cases of exanthematic fever at Toulon, a febrile disease developed. The infection was successfully transmitted to 2 other monkeys by intraperitoneal injection. Crossed inoculation experiments indicated that the exanthematic fever at Toulon is an attenuated form of exanthematic typhus.

7585. **NATTAN-LARRIER, L., G. ELIAVA, et L. RICHARD.** Bactériophage et perméabilité placentaire. *Compt. Rend. Soc. Biol.* 106(10): 794-797. 1931.—Pregnant guinea pigs were injected intracardially with coli bacteriophage. The animals were killed at various times after inoculation and the maternal and fetal bloods were tested for bacteriophage, by the Grasset technique. In no case did fetal blood contain bacteriophage, and in 1 case it was absent in maternal blood 24 hrs. after inoculation. Grasset's results were confirmed; those of Blair and Reeves, contradicted.—*E. Weiner.*

7586. **OLMER, [D.].** La fièvre exanthématique. *Office Internat. Hyg. Publ.: Bull. Mensuel [Paris]* 22(8): 1494-1521. 1 col. pl., 1 fig. 1930.—The distribution, so far reported, is in southern France, especially Marseilles, where the first cases were observed, in Spain, Portugal, on the Mediterranean coast of Africa and possibly in other parts of Africa, in India, and the U. S. A. The author was unable to transmit the disease from infected to uninfected monkeys by means of lice allowed to feed on a 1st set of animals, then pulverized and inoculated into a 2nd. It is probable, though not proved, that the medium of transmission is a tick (*Ixodes ricinus*) common in the affected regions; that the reservoir of infection is the dog; and that the characteristic eschar is the point of implantation of the tick. The history and clinical features of the disease are also reviewed.

7587. **PESCH, KARL L., und H. SIEGMUND.** Untersuchungen über den Erreger der Psittakosis. *Arch. Hyg. u. Bakt.* 105(1): 1-14. 1931.—Blood, urine and sputum from 5 patients, and tissues (lungs, lymph-nodes, spleen), heart-blood, bile, and material from the large and small intestines from 2 cadavers, all infected with psittacosis, were injected into, and animal transfers made to, 123 parakeets and 6 paddy birds. Microscopic, histologic, and bacteriological examinations showed that no bacterium of the paratyphoid group, no streptococcus, or other visible bacterium was the cause of psittacosis. Transfer of the disease by both filtered and unfiltered material indicated a filterable virus etiology.

7588. **[PREDTECHENSKIĬ, S. N.]** ПРЕДТЕЧЕНСКИЙ, С. Н. К изучению бактериофагов речных вод. (Contribution to a study of the river water bacteriophages.) Вестник Микробиологии, Эпидемиологии и Паразитологии. (*Rev. Microbiol., Épidémiol. et Parasitol.*) 8(3): 261-263; English summary, 353. 1929.—The author obtained from water of the Dnieper in Dniepropetrovsk, a bacteriophage with rather strong lytic action (1: 18,250,000 according to d'Herelle's method) for *B. coli* strains from the Dnieper, a somewhat weaker action for other coli strains, and no action for other intestinal bacteria. The bacteriophages of river waters may be of importance in epidemiological problems. Presence of coli-bacteriophage indicates fecal contamination; and bacteriophages may possibly play a part in the self-purification of river water. Moreover, in bacteriological examination, bacteriophage should be taken into consideration, as it may cause the disappearance of bacteria,

or their transformation into atypical variants.—*Author's summary.*

7589. **SELLARDS, ANDREW WATSON. The behavior of the virus of yellow fever in monkeys and mice.** *Proc. Nation. Acad. Sci.* [*Washington, D. C.*] 17 (6): 339-343. 1931.—A strain of virus from a yellow fever monkey, maintained by repeated passage from brain to brain in mice, until it no longer infected monkeys (*M. rhesus*) by ordinary routes of injection, was compared with the original strain maintained in monkeys and mosquitoes. Monkeys inoculated into the brain with a suspension of infective mouse brain, developed regularly a typical fatal encephalitis, but without characteristic changes in the liver. Blood of such animals proved non-infectious for monkeys in 2 experiments, one test being made by direct inoculation and the other by means of mosquitoes. Direct inoculation from brain to brain through a series of 4 monkeys failed to restore the virulence of the strain. 2 monkeys injected intracerebrally with infective blood of monkeys, died characteristically of yellow fever, with necrosis of the liver and without encephalitis. Tests for cross-immunity were carried out by injecting normal monkeys intraperitoneally with mouse virus and subsequently testing them with typical yellow fever virus. Also, monkeys immunized to typical yellow fever were injected intracerebrally with infective mouse brains. Cross protection was very well marked, though it was not complete. Intraperitoneal injection of infective mouse brains proved to be a very convenient method of immunizing monkeys against a typical potent strain of yellow fever. Results of these cross-immunity tests are entirely consistent with the interpretation that the virus was that of yellow fever.—*Author's summary.*

7590. **SHERMAN, JAMES, and CLAIR E. SAFFORD. The occurrence of filterable forms of bacteria in nature.** *Science* 73 (1895): 448-449. 1931.—Using Hadley's methods, with slight variations, the authors demonstrated filterable microorganisms in soils, decomposing manure, hay infusion, fresh human feces and milk.

7591. **SIMIĖ, TICHOMIR V. Rolle des Bakteriophagen bei der Bildung von Bakterienvarianten in pathologischen Produkten. Beitrag zur Erklärung ihres Wesens und ihrer Ursachen.** *Zentralbl. Bakt. I. Abt. Orig.* 115 (1/2): 74-77. 1929.—A variant of *B. typhosus* was isolated from various loci in typhoid fever. Morphological and cultural characters were atypical on plain agar, but approached normal on addition of fresh blood or potato extract. The variant was shown to be a carrier of bacteriophage, by which the author believes it was produced from the normal type. It could be cultured free of bacteriophage by serial transfer, retaining still its atypical characters. The observations are believed to support the view that bacteriophage is a living organism. —*J. B. Nelson.*

7592. **URÍZAR, R. La rabia en el Paraguay.** *An. Inst. Nacion Parasitol.* [*Paraguay*] 4 (4): 13-20. 1931.—This is the first report of laboratory diagnosis and clinical study of rabies in Paraguay. An outbreak in June, 1931, is described.

LOWER ANIMALS

7593. **BIERBAUM, K., E. EBERBECK, K. RASCH, und W. KAYSER. Weitere Untersuchungen über Geflügelpocken.** *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39 (1/2): 141-149. 1931.—In agreement with earlier work, it appears that the fowl-pox virus may be adapted to pigeons by passage. In these studies, success was obtained only with a strain of fowl-pox virus which had formerly been bipathogenic and may have been mixed. This virus gave lesions only at the point of inoculation and in the mouth of chickens, and small lesions at the point of inoculation in pigeons. Histologically, the lesions in the fowls were not characteristic until about the 15th passage. After passage through 11 pigeons the virus was no longer pathogenic for fowls, and after a passage through 6 fowls it was no longer pathogenic for pigeons, passage increasing the virulence for homologous birds.—*L. D. Bushnell.*

7594. **MEYER, K. F., C. M. HARING, and B. HOWITT. Newer knowledge of the neurotropic virus infections of the horse.** *Jour. Amer. Vet. Med. Assoc.* 32 (3): 376-389. 1931.—The evidence thus far obtained in California indicates that the American encephalitis differs etiologically from the Moussu-Marchand type and from Borna's disease. Until further investigations are completed it must remain undecided whether the American disease is due to an elective neurotropic virus or whether it is an encephalomyelitis with organotropic properties of the virus, as, e.g., is the case in hog cholera, distemper, fowl pest, and yellow fever.—*Authors' conclusions.*

7595. **MURPHY, JAMES B., O. M. HELMER, ALBERT CLAUDE, and ERNEST STURM. Observations concerning the causative agent of a chicken tumor.** *Science* 73 (1888): 266-268. 1931.—Purification of the extract of a filterable chicken tumor was carried on by precipitation, and by adsorption. The active material is precipitated at pH 4.4-4.8. When the material was adsorbed on $Al(OH)_3$, the remaining supernatant fluid was much more active than was the original extract; the adsorbat, after release, was much less active. As far as could be determined, the former contained no protein. This purified fraction produced a high content of neutralizing bodies when injected into rabbits, but failed to produce precipitins or complement-fixing antibodies. When a tumor desiccate was repeatedly washed with water, both the water and the residue became more active with each successive washing, indicating that there existed, along with the active principle, an inhibitor, which was more soluble than the active factor. The fact that the supernatant fluid remaining after adsorption is so highly active, is also explained in this way.—*J. B. Murphy.*

7596. **SJOLLEMA, B., en L. SEEKLES. Borna-ziekte bij het paard en grastetanie bij het rund. [Borna's disease in horses, and grass tetany in cattle.]** [With German, French and English summaries.] *Tijdschr. Diergeneesk.* 58 (15): 809-812. 1931.—Because of the striking similarity of symptoms of grass tetany in cows and Borna-disease in horses, the authors examined the blood of a horse with Borna-disease. They found that a most important symptom of grass tetany—the characteristic disturbance in the mineral equilibrium of blood serum—did not occur in Borna-disease. Moreover, the instantaneous curative effect of an intravenous injection of $CaCl_2$ in grass tetany, makes its supposed infectious origin very improbable.—*Authors' summary.*

7597. **WEFRING, K. Fièvre aphteuse produite par l'inoculation du vaccin antivariolique chez les vaches.** *Office Internat. Hyg. Publ.: Bull. Mensuel* [*Paris*] 22 (9): 1714-1716. 1930.—An outbreak of foot-and-mouth disease of Oslo followed small-pox vaccination. Sources of infection other than the vaccine were excluded, and further experiment indicated contamination of the vaccine virus. This vaccine is the same as that used in the vaccination of about 8,000 children, but in them no complication has been reported.

7598. **WINKEL, A. J. Iets over de stammen van het monden klauwzeervirus in Nederland gedurende de laatste drie jaren. [Types of foot-and-mouth disease in Holland during the last three years.]** [With German, French and English summaries.] *Tijdschr. Diergeneesk.* 58 (15): 793-801. 1931.—24 examinations were made by testing the serum (15 times by direct inoculation of guinea pigs immunized against both types A and O). In 1928 and 1929, the strains belonged to the A type; since the spring of 1930, only the O type has been observed. Experiment proves that injection with one type only may confer a heterologous immunity.—*Author's summary.*

(See also in this issue Entries 6574, 7156, 7191, 7192, 7195, 7210, 7220, 7236, 7237, 7287, 7288, 7308, 7344, 7353, 7371, 7385, 7392, 7399, 7587, 7665, 7674, 8055, 8056, 8060, 8078, 8079, 8080, 8092, 8263)

7599. AGOSTINI, A. Dermatomycose due à "Eurotium rubrum" Bremer. *Soc. Internaz. Microbiol. Boll. Sez. Italiana* 3(1) : 24-25. 1931.—Symptoms of a case of scalp dermatomycosis, with description of the fungus isolated.

7600. BELEZKY, W. K., und R. M. UMANSKAJA. Die Recurrensspirochätose des zentralen Nervensystems des Menschen. *Zeitschr. Ges. Neurol. u. Psychiatr.* 129 (1/2) : 21-41. 6 fig. 1930.—In 3 of 5 of the authors' cases in which spirochaetes were found in various organs, they found Obermeier's spirochaetes in considerable numbers in the gray matter of the brain and medulla and in the pia. Finding of spirochaetes in the brain parenchyma is dependent on their great numbers in the blood stream, the spirochaetes penetrating directly into the central nervous system through blood vessel walls or through the subarachnoid space and overlying glial membrane. They spread diffusely in the central nervous system, especially in the superficial cortical layers, without relation to the vessels in limited portions of the parenchyma. Spirochaetes which have penetrated into the brain are destroyed by extracellular lysis and also by phagocytosis by the cell elements of the glia. Among the latter, the Rio-Hortega cells (mesoglia cells) seem to play the principal rôle. These cells function similarly to the histiocytes of the reticulo-endothelial apparatus and the blood macrophages of histiocyte origin. In the pia one finds some infiltration of monocytes, lymphocytes, plasma cells, and also of histiocytes with but little such infiltration in the vessel walls of the brain parenchyma. In man, lytic antibodies play a major rôle in overcoming *recurrentis* infection, by dissolving the spirochaetes both in tissues and blood stream. We must consider the phenomena of lysis and phagocytosis, which occur simultaneously in tissues and blood stream, as defense mechanisms in the reaction against *recurrentis* infection. Obermeier's spirochaetes can be present in considerable numbers in the central nervous system, even if they are to be found in very small numbers or not at all in other organs or in the blood stream. Morphological analysis of the defense apparatus of the central nervous system (phagocytosis and lysis) shows a weak and delayed functioning of that system in comparison with other organs.—*Authors' summary (transl. by H. E. Meleney)*.

7601. BIELING, R. Untersuchungen über die Erreger des undulierenden Fiebers. *Zeitschr. Hyg. u. Infektionskr.* 111(5) : 728-739. 1930.—While morphology, cultural methods, comparative agglutination of the various strains with monovalent sera, etc., furnish no trustworthy criterion for distinguishing human and bovine *Brucella* strains from central Europe and from the eastern Mediterranean basin, the author's agglutination-binding method, especially applied to supervalent sera, enabled him, in tests on 28 human and 27 bovine strains of various origin, to distinguish 2 great groups: (1) the Mediterranean human type, and (2) the Central European bovine type. Both types, however, may infect either man or animals; and, no matter what the type of infecting organism, human infection presents the picture of undulant fever; the animal disease, that of infectious abortion. It is improbable that the Mediterranean type occurs in Germany and adjacent countries. In Bulgaria it predominates among human infections, while the German bovine type dominates among animal infections. In Palestine the Mediterranean type seems to be solely responsible for human infection, but the German bovine type occurs among cattle, especially in imported animals.

7604. BRANHAM, SARA E., GEORGE W. McCOY, and CHARLES ARMSTRONG. Bacillus psittacosis Nocard, 1893. Failure to find it in the 1929-30 epidemic in the United States. [*U. S.*] *Public Health Repts.* 45 (37) : 2153-2160. 1930.—During the recent outbreak of psittacosis in the U. S. A., an intensive search for the *B. psittacosis* Nocard was made in the carcasses and droppings of parrots shipped to the National Institute of Health, in experimentally infected and in normal parrots and parrakeets, and in material obtained from human cases. No strain of *B. psittacosis* or of any other member of the *Salmonella* group was found. In 57 convalescent sera studied, agglutinins for *B. psittacosis* or other Salmonellas were not demonstrable in dilutions that could be considered significant. No evidence of the association of any member of the *Salmonella* group with psittacosis either in birds or in man was found.—*Authors' summary.*

7605. BRUCE, L. C. A suggested cause of nephrosis. *Lancet* 220(5605) : 26S. 1931.—The author suggests from his clinical observations that some cases of nephrosis are of bacterial origin. Urine in culture showed streptococci and colon bacillus (1 case), *Staphylococcus aureus* (3), colon bacillus (2), and *Micrococcus tetragenus* (1). When treated with autogenous vaccine all but the last case cleared up.

7606. CANN, L. W., and G. J. HOLLIS. A case of actinomycotic cerebro-spinal meningitis associated with aural actinomycosis. *Lancet* 220(5603) : 130-131. 1931. —The *Streptothrix* mycelium present in the cerebrospinal fluid could not be identified; it showed Gram-positive branching filaments. When incubated anaerobically in glucose broth, a granular sediment appeared after 5 days; this showed no branching filaments.

7607. CASTELLANI, ALDO. Tonsillomycoses: a brief general account. *Practitioner* [*London*] 1930(Jan.) : (2-16). 11 fig. 1930.—Fungi of the following genera have been isolated by the author as etiological agents in mycotic infections of the tonsils: *Cryptococcus, Saccharomyces, Debaryomyces, Monilia, Endomyces, Oidium, Hemispora, Willia, Trichosporium,* and *Nocardia.* A brief description of the methods of classification of the various genera, based on the occurrence of budding, mycelial and ascus production, is given. Tonsillomycoses are here classified from a clinical rather than an etiological basis, since many fungi of different genera may cause the same pathological picture. Diseases of the tonsils due to fungi run an acute or chronic course; follicular or diphtheritic inflammations comprise the acute types. *Monilia* spp. are the causative organisms in the majority of cases, but any of the above organisms may be isolated. In the chronic group, 3 types of lesions result: (a) tonsillar and peritonsillar abscesses from which *Nocardia* may be demonstrated, at times in the form of granules; (b) diphtheritic tonsillitis, giving rise to brownish membranes, occasionally spreading over the fauces (the author isolated *Hemispora,* but Otta found *Trichosporium* in this type of lesion); (c) tonsillomycoses spinulosa, with small white or grayish-white spicules in the crypts, from which *Oidium* can be cultivated. According to the author, diagnosis of tonsillomycoses

is made on the following grounds: finding of the specific fungus on smear; its isolation and identification by culture; absence of diphtheria bacilli; absence, or presence in very small numbers, of pyogenic cocci or the organisms of Vincent's angina; and, finally, presence of a membrane which is softer, less adherent, with less ulcerated base and with less tendency to bleed when removed, than that due to diphtheria bacilli.—*L. D. Michelson.*

7608. **CHAUSSINAND, R., et G. TEMPÉ. Contribution à l'étude de l'innocuité du BCG chez le nourrisson.** *Ann. Inst. Pasteur [Paris]* 45(1): 65-70. 1930.—A 7-months-old hydrocephalous monster, intraperitoneally injected with 2 mgm. BCG, presented no active tuberculous lesions at necropsy 4 months later; inoculation of guinea pigs with material from mesenteric ganglia was negative. The infant's death was attributed to the hydrocephalus or to a massive dose of vigantol. A normal infant, born of a tuberculous mother, received 60 mgm. BCG by mouth from the 4th to the 9th days after birth. At the age of 6½ mo. the child was well, weighed 6,480 gm., and the lungs showed normal in roentgenogram.

7609. **COHN, ALFRED. Verimpfung von Gonokokken auf Kaninchen.** *Dermatol. Zeitschr.* 60(1/2): 35-41. 1930.—After anesthetizing the eye, 0.2-0.25 cc. aqueous humor was aspirated from the upper limbus and 0.2-0.25 cc. gonococcal suspension injected. Of 54 rabbits so inoculated with 12 strains and 1 with a mixture of 11 strains, positive cultures were obtained in only 21 after 4-28 days. No strain was positive in all instances; 4 strains and the mixed suspension were entirely negative. In successful inoculation, the 7th to 13th days were best for removal of material. Inoculations into the testis and by suboccipital puncture were negative (2 tests each).

7610. **DAVANZO, I. Sulla batteriemia mestruale.** [Menstrual bacteriemia.] *Clin. Ostetrica* 32(11): 683-686. 1930.—Of 30 patients examined, 3 gave negative results during the premenstrual period, but bacteriemia (diplococci or streptococci) during menstruation; in 2 cases there was no clinical disturbance; in 1 there was high menstrual temp. The author believes it probable that bateria regularly present in the genital organs enter the circulation during the menstrual period.

7611. **DOLFINI, GIULIO. Contributo sperimentale sul potere patogeno del vaccino di Calmette.** [Pathogenic activity of Calmette's vaccine.] *Biochem. e Terapia Sperim.* 18(2): 41-49. 1 fig. 1931.—BCG when injected intravenously suspended in oil into guinea pigs does not acquire an increased virulence.—*M. Comel.*

7612. **DOULL, JAMES A., MARY HARDY, JANET H. CLARK, and NATHAN B. HERMAN. The effect of irradiation with ultra-violet light on the frequency of attacks of upper respiratory disease (common colds).** *Amer. Jour. Hyg.* 13(2): 460-477. 1931.—A group of 363 adult volunteers was kept under observation for 35 wks., and a vigorous effort was made to secure reports of all cases of upper respiratory disease. Approximately ½ were selected at random for irradiation, which was given over the first 31 wks. Mercury-vapor lamps were used and the intensity of erythema-producing rays was measured bi-weekly. The dosage was light to moderate, individuals being stripped to the waist and exposed, either on chest or back on each occasion, to that dose which, from previous experience with the subject, seemed likely to produce only a minimal erythema. Total incidence for the period was slightly higher for the irradiated (receiving more than 10 treatments) than for the controls. Also, cases of a more severe type, as evidenced by absence from duty and confinement to bed, by occurrence of fever, by productive cough or by long duration, were just as frequent in the irradiated as in the control group.—*Authors' summary.*

7613. **EINAUDI, MARIO. Contributo allo studio della constanza del potere emolitico del B. coli isolato durante interventi chirurgici. [Constancy of the hemolytic power of B. coli isolated during surgical intervention.]** *Lo Sperimentale* 84(4): 179-184. 1930.—The hemolytic power of 10 strains of *B. coli* isolated during surgical intervention was a constant property of the organism and not dependent upon environment or nutritional conditions. In order to insure uniform experimental conditions, however, it is advised that dog blood agar be used as culture medium.—*M. L. Menten.*

7614. **ELBERT, B., et S. GELBERG. Nouvelles contributions à l'étude expérimentale du BCG.** *Ann. Inst. Pasteur [Paris]* 45(1): 59-64. 1930.—Prolonged observations of a great number of guinea pigs inoculated with massive doses of initial BCG (50 mgm. peritoneally or 10 mgm. intratesticularly), and of 169 guinea pigs inoculated in the same doses with 25 different cultures from 10 successive passages, showed no increase of virulence over the original strain. BCG proved perfectly stable in all the authors' experiences.—*Authors' summary (transl.).*

7615. **ELKELES, GERHARD. Zur Klinik und Bakteriologie der E-Ruhr.** *Deutsche Med. Wochenschr.* 55 (10): 393-394. 1929.—On dysentery due to *Bacillus* E of Kruse.

7616. **[FIGATNER, R. I.] ФИГАТНЕР, Р. И. К методике выделения чистых культур. [Methods of obtaining pure cultures of tubercle bacilli.]** [With French summary.] Вопросы Туберкулеза. [*Voprosy Tuberkuleza*] 7(10): 1228-1231. 1929.—Sputa from 47 patients were sown both on egg medium after Hohn's method, and on the potato medium of Löwenstein and Sumiyoshi. Pure cultures were obtained by the latter method in 86%. In Hohn's method, 5 of 8 cases gave positive results. Egg medium is somewhat preferable, because it sometimes produces cultures sooner than the other, and also allows use of Hohn's method, which is much simpler than that of Löwenstein and Sumiyoshi.—*B. Van Rosen.*

7617. **FISCHL, RUDOLF, BERTHOLD EPSTEIN, und FRIEDRICH BREINL. Experimentelle Beiträge zur Erforschung der kongenitalen Syphilis.** *Arch. Kinderheilk.* 83(1/2): 44-56. 1928.—The authors inoculated material from syphilitic rabbit testes into scarified genitalia of female rabbits without producing infection. 2 pairs of syphilitic rabbits were mated; the living and dead offspring showed no signs of syphilis. 8 rabbits were infected in the anterior chamber of the eye; 1 developed local syphilitic manifestations, and 1 general manifestations. Syphilitic males mated with normal females produced syphilis neither in the female nor in its offspring. Intravenous and intracardial injections of emulsion of syphilitic testes into 3 rabbits produced no positive results. Repeated injection of blood from a congenital syphilitic woman into a male rabbit failed to influence the course of subsequent intratesticular inoculation. Efforts to infect female guinea pigs subcutaneously were followed by negative findings, both in the females and in their offspring.—*S. W. Becker.*

7618. **FLORENCE, LAURA. Viability and retention of virulence of a culture of Corynebacterium diphtheriae.** *Science* 73(1897): 495. 1931.—Cultures from chocolate agar transferred to bits of sterile filter paper in Wassermann tubes kept in vacuo in anaerobic Smillie jars retained virulence for long periods.

7619. **FOTHERGILL, LeROY D. Unusual types of non-lactose-fermenting, gram-negative bacilli from acute diarrhea in infants.** *Jour. Infect. Dis.* 45(5): 393-403. 1929.—An attempt was made to classify gram-negative, non-motile, non-liquefying, so-called atypical paratyphoid bacilli, isolated from 104 cases of intestinal disturbance and to show their possible causal relation to summer diarrhea. A table showing Weldin's classification of various known intestinal bacilli is given and discussion on this point is limited to this classification. Detailed cultural and serological reactions of 32 strains emphasize their heterogeneous nature. By cross-agglutination, less than 50% fall into 3 groups, one of which checks culturally with strains noted as fermenting sucrose. No group-agglutinins with the paratyphoid group were observed, indicating lack of common antigen. Serums from 18 cases were studied and agglutination was observed in 55.5% with strains of this sucrose-fermenting group. Following a brief discussion of the etiology of summer

diarrhea, the author concludes that the so-called atypical paratyphoid bacilli have no logical place in present classifications, and that as yet proof is incomplete as to their etiological relation to summer diarrhea.—*L. N. Batt.*

7620. **FREDRICH, E. Vergleichende Untersuchungen zum Nachweis von Tuberkelbacillen durch Tierversuche und mit dem Nährboden nach Hohn.** *Beitr. Klin. Tuberk.* 76(4/5): 489-492. 1931.—Of 54 specimens, 35 were positive: 5 on Hohn's medium only, 6 in animals only, 24 in both; cultures should be designated negative only after 60 days. Of the 28 specimens treated with antiformin, 2 were positive to Hohn only, 3 to animal only, 8 to both; of 26 treated with H_2SO_4 the positives were 3, 3, and 16, respectively.

7621. **GEIGER, RICHARD. Über den Nachweis und das Vorkommen von Spirochäten im Liquor bei Frühluetikern.** *Arch. Dermatol. u. Syph.* 162(3): 473-479. 3 fig. 1931.—Spirochaetes were found in 12 of 30 cases of early lues, using the silver agar method of Warthin and Starry. They were present in 2 seropositive cases of sclerosis, in all of 5 cases showing positive spinal fluid reaction, and in 7 of the 25 (inclusive of the 2 cases of sclerosis) with negative spinal fluid reaction.

7622. **GHEORGHIU, I. Un caz de Salmonela la om provocată de B. aertrycke.** [Human infection with Bacillus aertrycke.] *Rev. Med.-Chir. Iasi* [*Rumania*] 38(2): 26-27. 1927.

7623. **GOIFFON, R., et E. DONY. Relation entre la fréquence des blastocystis, des spirilles, des lamblias et des amibes du côlon avec les autres éléments coprologiques.** *Arch. Malad. Appar. Digest. et Malad. Nutrit.* 20(7): 858-861. 1930.—The authors compare the frequency of coincidence of *Blastocystis*, spirilla, *Giardia intestinalis* and *Entamoeba coli* with acidity, excess ammonia, accelerated evacuation, etc., and find that there are merely differences in frequency of occurrence among the parasites in relation to the various conditions mentioned. No definite type of stool is an invariable condition of environment for any organism.

7624. **GORDON-TAYLOR, G., and LIONEL E. H. WHITBY. A bacteriological study of fifty cases of cholecystectomy with special reference to anaerobic infections.** *Brit. Jour. Surg.* 18(69): 78-83. 1930.—From observations on 50 cases and a review of the literature, the authors conclude that intestinal bacteria are the most frequent organisms in gall-bladder disease and that *Bacillus welchii* (found in nearly 9% of gall-bladders removed by operation and in the center of 13% of gallstones obtained from postmortems) is usually associated with the acute form of cholecystitis.

7625. **IVANIĆ, STEVAN, und V. DIMITRIJEVIĆ-SPETH. Beobachtungen bei der Prüfung unseres Schwärmverfahrens an Krankenstühlen.** *Zentralbl. Bakt. I. Abt. Orig.* 115(1/2): 78-79. 1929.—Results by this method (previously described) were compared with those by Müller's tetrathionate medium on 100 stools. The flocculation method gave better results with typhoid stools, but with paratyphoid B stools fewer positives were obtained. However, by Müller's method bacteria were obtained from healthy individuals, which exhibited the fermentative properties and agglutinability of paratyphoid B but differed in their slight ability to clump and in their failure to blacken lead acetate on Calmette's medium, thus rendering the diagnosis more difficult.—*G. H. Robinson.*

7626. **KADISCH, E. Das Sauerstoffbedürfnis der pathogenen Hautkeime und seine Bedeutung für den Dermatotropismus.** *Arch. Dermatol. u. Syph.* 162(2): 462-472. 5 fig. 1930.—Previous investigations indicated that dermatotrophism in the dermatophytes is due to the lower temp. of the skin. Since they rarely attack squamous epithelium except where there is more or less free access of air, O appears to be a factor in dermatotrophism. Agar plate experiments with more than 15 species of dermatophytes under anaerobic conditions, showed the necessity of O for growth. This was substantiated by other anaerobic, partially aerobic, and aerobic experiments in culture and in vivo with either *Ach*[*orion*] *gypseum* or *Ep*[*idermophyton*] *inguinale*. Peritoneal and pneumoperitoneal experiments with guinea pigs and frogs indicated that temp. is more determinant than O. Cultures on living and dead sections of *Cereus peruvianus*, temp. and O being constant, showed that the living cell contains factors not permitting growth of *A. gypseum*.

7627. **KAIRIŪKŠTIS, VLADAS. Kai-kurios plaučių tuberkuliozės savybės miesto ir kaimo gyventojams. (Plaučių tuberkuliozės apsikrėtimo teorijos pastebėtų faktu šviesoje Plaučių ligų lokalizacijos dėsningumas apskritai.) [Certain characteristics of pulmonary tuberculosis in urban and rural patients.]** [With German summary.] *Medicina* [*Kaunas, Lithuania*] 11(2): 95-101. 1930.—Study of 1155 ambulant patients and of various collections of roentgenograms indicated that the right lung is more frequently infected in city dwellers; the left, in peasants; there were also certain differences in the course of the disease. Various explanations offered for the greater receptivity of the right lung are insufficient, in the author's opinion, to explain the known facts. He explains the frequency of left lung infection in the country by the insanitary eating habits of the peasants: infection taken with food passes through the gastric wall into the lymphatic system by way of the thoracic duct which is closely connected with the lymphatic system of the left lung, just as gastric cancer metastasizes by way of the thoracic duct more frequently into the left lung than into the right.—*From author's summary (transl.).*

7628. **KENDALL, ARTHUR ISAAC, and SANFORD ROBINSON GIFFORD. Trachoma and avitaminosis.** *Arch. Ophthalmol.* 4(3): 322-325. 1930.—Vitamin A was removed from the diet of 3 series of white rats (36 in all) for various periods; some rats in each series were kept as controls, and the remainder inoculated with *Bacterium granulosis*. Results were negative. It is concluded that lack of vitamin A is not necessarily a factor in trachoma infection.

7629. **KLIGLER, I. J., und L. OLITZKI. Der Infektionsmechanismus bei der peroralen Gärtnerinfektion der Mäuse.** *Zeitschr. Hyg. u. Infektionskr.* 111(5): 711-727. 1930.—The course of infection in 516 mice, for a weakly virulent strain of *Bacillus enteritidis* Gärtner, orally introduced, was studied by examination of organs. In 175, all organs and glands were sterile. The sole route of infection was from intestines to glands, including passage of the bacteria into the blood stream and formation of bacterial foci in liver and spleen. The bacteria could be found in the intestines in all 3 stages of the disease. In the incubation stage, the majority of positive findings were in the lower intestinal sections; at the peak of infection, mostly in the upper intestinal segments; and at the stage of subsidence (carrier stage), only in the upper intestinal tract. Intravenous injection of the same strain into 18 mice showed that the liver and spleen absorb large numbers of the bacilli; in 5 animals all organs were completely sterile in 24 hrs. Hence, a primary sepsis proceeding from the intestines seems improbable. External factors such as temp. and atmospheric moisture had a distinct effect on severity and mortality, but apparently none on localization of the pathogenic agent.

7630. **KNEELAND, YALE, Jr. Studies on the common cold. III. The upper respiratory flora of infants.** *Jour. Exp. Med.* 51(4): 617-624. 1930.—30 normally delivered infants were studied from the time of birth to the age of 4-8 mo. At birth the upper respiratory tract is sterile. During the first 2 weeks of life the infant acquires a basal bacterial flora comparable to that of adults, not including the potential pathogens referred to below. During the ensuing months these potential pathogens, such as Pfeiffer's bacilli, hemolytic streptococci and pneumococci, which did not appear in the first 2 weeks, first made their appearance without apparently giving rise to respiratory symptoms. However, in infants with recurrent colds, pneumococci and Pfeiffer's bacilli seemed to play the part of secondary infective agents. None of the bacteria cultured from the respiratory tracts of these

infants semed to play the part of specific incitants of their first colds.—*G. S. Shibley.*

7631. **KUSAMA, SHIGERU, TOSHIHISA YOKOYAMA, and NARIYOSHI ITO.** Bacteriological studies of measles, Part 1. Bacteriological studies of the etiology of measles with Japanese monkeys. *Kitasato Arch. Exp. Med.* 7(3) : 217-225. 1930.—The authors cultivated a new bacillus by inoculating the kidney of Japanese monkeys infected with measles into ascites broth. Morphologically, it resembles the causative agent of typhus, which is cultivated by the same method. It is a facultatively anaerobic coccobacillus growing only in liquid media such as ascites or serum-broths and not on slants of various solid media. When cultivation is repeated, growth becomes easier and at last it grows aerobically in liquid media. In glucose agar stab media growth occurs along the stab line. It is difficult to produce strongly immune sera. Among domestic animals, horses are very susceptible to the virus.—*Authors' summary.*

7632. **LABERNADIE, V. Contribution à l'étude de la contagiosité de la lèpre.** *Rev. Méd. et Hyg. Trop.* 22 (3) : 114-137. 1930.—Leprosy affects 2.5% of the native half-breed population of French Guiana. In 1883 the 1st cases (2) were observed among the convicts of the penal settlements. Since then the number has risen to 80 and the proportion to 1.3-1.4%. As the convicts receive thorough medical examination before and after transportation, as intercourse with the natives is not difficult, and as the convict cases arise among those long in the country, and those who have earned a measure of freedom, the author regards the evidence for contagiousness as convincing. Incidentally, the conditions at the leper settlement are so far superior to those to which the mass of the convicts are subject, that it is regarded as a privilege to be pronounced leprous.

7633. **LANGE, BRUNO. Untersuchungen zur Klärung der Ursachen der im Anschluss an die Calmette-Impfung aufgetretenen Säuglingserkrankungen in Lübeck.** *Zeitschr. Tuberk.* 59(1) : 1-18. 1930.—The tubercle bacilli obtained from 3 infants dying of tuberculosis after ingesting inoculation material prepared in Deycke's laboratory, produced progressive tuberculosis in guinea pigs; the same was true of a culture from the tuberculous cervical glands of another child. Mesenteric glands, microscopically showing tubercle bacilli but macroscopically healthy, from a child who died intercurrently during a favorable period of inoculation, did not produce progressive tuberculosis. In repeated inoculations of 2 BCG cultures, one used during the period of many fatalities produced progressive tuberculosis in guinea pigs; the other, used during a favorable period, showed greatly weakened virulence, even in repeated transfer. The investigations would indicate a mixture of BCG culture with a pathogenic strain, probably one from Kiel, present in the laboratory at that time. The pathogenic strains from the infants as well as the strain sent from Kiel to Lübeck were both of labile virulence, which would account for many children surviving. Further investigations must be made to determine the type both of the Kiel strain and of those pathogenic to infants. The investigations revealed nothing to indicate that the fatalities were due to a spontaneous increase in virulence of BCG.

7634. **LASSEN, H. C. A. Om infektionsforløbet efter oral indgift af Bac. aertrycke (Breslau) hos mus paa B-vitaminfri kost. [Oral infection with Bacillus aertrycke Breslau of mice on a vitamin-B-free diet.]** *Hospitalstidende* 72(19) : 506-512. 1929.—20 mice on a B-vitamin-free diet showed, after a peroral dose of 16 drops of a 16-hr.-old Breslau culture, exactly the same duration of infection as 19 mice kept on a diet of moistened white bread and grain. It was impossible with the technique used to show any depression of resistance in white mice on a B-vitamin-free diet.—*K. C. Berthelsen.*

7635. **LEURET, E., et J. CAUSSIMON. Lésions consécutives à l'injection sous-cutanée de bacilles biliés de Calmette et Guérin (BCG) au cobaye. Tentatives infructueuses de réinoculation.** *Compt. Rend. Soc. Biol.* 98(17) : 1537-1538. 1928.—Attempts to reinoculate from guinea pigs inoculated with BCG were unsuccessful.

7636. **LEVIN, OSCAR L., and SEYMOUR H. SILVERS. The isolation of ringworm fungi from sweat.** *Arch. Dermatol. & Syphilol.* 23(6) : 1094-1099. 2 fig. 1931.—Cultures of apparently pathogenic fungi believed to belong to the Kauffmann-Wolff group, also bacteria, *Aspergillus niger* and yeast-like organisms, were obtained from the sweat of the feet in 5 of 8 patients (affection not stated).

7637. **LEWIS, C. J. Note on the Bacillus psittacosis.** *Birmingham Med. Rev.* 5(12) : 424-429. 1930.—Cultures and filtrate of broth cultures of *B. psittacosis* obtained from parrot feces were tested in 8 guinea pigs and 2 budgerigars by feeding; by subcutaneous, intra-thoracic, intra-muscular inoculation; and by instillation into the nostrils, with and without abrasion. Lungs and bone marrow were most affected. Since the definite relationship between *B. psittacosis* and human cases of psittacosis has not been established, the author recommends necropsy cultures of human bone marrow.

7638. **LUZZATO-FEGIZ, G. Studio istologico sulle reazioni provocata da un micobatterio tubercolare umano avirulento. [Histologic study of reactions produced by a human avirulent strain of Mycobacterium tuberculosis.]** *Bull. e Atti R. Accad. Med. Roma* 56(10) : 287-296. 1930.—Subcutaneous inoculation into guinea pigs of Puntoni's avirulent human strain of *M. tuberculosis* produced subcutaneous abscesses which healed spontaneously with no diffusion to glands or other organs. Intraperitoneal injection produces on the omentum large abscessed nodules inclosing all the germs injected. The abscesses are histologically very different from those produced by the common pyogenic organisms and persist for months as a "caput mortuus," without producing any diffusion to the rest of the organism. Healing is produced either by the disappearance of the little abscessed nodules or, in the larger ones, by thickening of the fibrous capsule of the abscess, which becomes sterile through gradual destruction of all the bacteria.

7639. **McKINLEY, EARL B. Failure to confirm Rosenow's work on encephalitis in its relation to green streptococcus.** *Proc. Soc. Exp. Biol. & Med.* 27(5) : 436-440. 1930.—Using Rosenow's technique, swabs from the tonsils of normal persons yielded green-producing streptococci; such swabs, injected intracerebrally into 50 rabbits, led to death in 40, with symptoms of typical encephalitis; green-producing streptococci were recovered from the brains of 35. Injections into 24 mice, 24 guinea pigs, and 3 monkeys showed but slight virulence of the streptococci for these animals. The author concludes from these and other evidences here presented that green-producing streptococci have no etiological relationship to encephalitis.

7640. **MOUTOUSSIS, KONSTANTIN. Befunde von rickettsiaartigen Gebilden und Einschlüssen in mit Denguefiebervirus infizierten Stegomyien.** *Arch. Schiffs- u. Tropen-Hyg.* 33(6) : 330-333. 1 pl. 1929.—During an epidemic in Greece, mosquitoes were fed on patients suffering from dengue fever. In the intestines of 15 such mosquitoes, but not in the salivary glands, Rickettsia-like bodies* were found.—*A. S. Pearse.*

7641. **MUSGER, ANTON. Zur Ätiologie der Nicolas-Durand-Favre'schen Krankheit, der sog. Lymphogranulomatosis inguinalis.** *Beitr. Path. Anat. u. Allgem. Path.* 80(2) : 257-269. 8 fig. 1928.—The author cultured bacteria and observed them microscopically from the gland and glandular tissue of the 1st case of Nicolas-Durand-Favre's disease in Vienna. The cultures were pathogenic for laboratory animals. In guinea pigs they produced alterations in the glands, which seemed macroscopically and microscopically identical with those in man. Vaccines prepared from the cultures produced positive skin reactions in sick persons. In view of these observations, it is concluded that the bacteria (Corynebacteria) have a distinct etiologic relationship to the disease. The same bacillus was isolated from the gland and the blood of a 2nd patient.—*P. G. Heineman.*

7642. **NÉLIS, P.** Sur l'absorption per os des bacilles de la fléole chez le cobaye et le lapin. *Ann. Inst. Pasteur* [*Paris*] 45(5): 581-595. 1930.—Absorption of timothy bacilli from the gastro-intestinal mucosae was studied for its bearing on oral administration of BCG, since timothy bacilli are acid-fast like tubercle bacilli, but have the advantage of being non-pathogenic and easily cultivated on artificial media. In 1 of 5 adult guinea pigs and in several of 15 adult rabbits the bacilli were recovered from the blood or organs 3-4 hrs. after ingestion, indicating that passage through the gastro-intestinal mucosae is possible, but irregular and difficult. In 22 guinea pigs aged 5 days or less and in 14 rabbits aged 8-10 days, given oral doses of the bacilli and killed at various intervals thereafter, of those killed 1-5½ hrs. after injecting the bacilli the large majority presented colonies in the blood or organs, indicating that in the young of these animals gastro-intestinal absorption of acid-fast bacilli is comparatively rapid, constant and abundant. In addition, 1 mgm. of a virulent bovine strain of tubercle bacilli was administered to each of 7 adult and 7 new-born guinea pigs; the young guinea pigs all gave a distinct positive intracutaneous reaction 1-2 mo. after ingestion, while 6 of the adult animals gave a negative reaction. At necropsy 4 months after ingestion, the adults were free from tuberculosis; the young showed a generalized tuberculosis.

7643. **NICKEL, ALLEN C., and E. STARR JUDD.** Cholecystitis: a bacteriologic and experimental study of three hundred surgically resected gall bladders. *Surg. Gynecol. & Obstetr.* 50(4): 655-662. 6 fig. 1930.—The majority of surgically resected gall bladders from patients with acute or subacute cholecystitis contain pathogenic bacteria; the majority from patients with chronic cholecystitis are sterile. The organisms are, according to their frequency, green-producing streptococci, gram-negative bacilli, and staphylococci. Streptococci isolated from grossly diseased gall bladders tend to reproduce the cholecystitis and cholelithiasis in experimental rabbits, when injected intravenously. The colon bacillus may have a selective action for the gall bladder. It is usually found with the streptococcus, and appears frequently in relatively acute cases or in cases in which there are stones in the common or cystic duct. Staphylococci were found to be non-pathogenic for gall bladders of rabbits when injected in pure culture.—*H. A. Austin.*

7644. **NINNI, G.** Résultats de l'inoculation de produits suspects de tuberculose dans les ganglions lymphatiques. *Ann. Inst. Pasteur* [*Paris*] 45(4): 433-438. 1930.—The author found that intraganglionic inoculation of guinea pigs rapidly enhances the virulence of tuberculous material and tends to purify the culture by destroying other bacteria. The method is thus superior to that of subcutaneous inoculation.

7645. **NOGAMI, T.** Ueber Kulturversuche von Mikroorganismen im trachomatösen Gewebe. *Klin. Monatsbl. Augenheilk.* 86(3): 313-316. 3 fig. 1931.—From 32 trachoma cases the author isolated Ochi's organism in 19, and from 9 he obtained pure cultures. It was both aerobic and anaerobic; the spores were first more or less conical, then oval; mycelia developed 1 mo. later. Serum agglutination tests (Ochi found the organisms phagocytized by polymorphonuclear leukocytes which migrated into the vessel lumina) on 30 trachomatous patients, 8 with healthy conjunctiva and 3 with catarrhal conjunctivitis, gave positive agglutination at 1:160 and sometimes at 1:320 in those with trachoma; controls were negative. (See also the following abstract.)

7646. **OCHI, S.** Ueber eine Art von Mikroorganismen im trachomatösen Gewebe. *Klin. Monatsbl. Augenheilk.* 86(3): 309-313. 1931.—From the conjunctiva of many trachomatous patients the author isolated an organism which could be transferred to man and again cultivated from the conjunctiva; transfers to monkeys, rabbits, guinea pigs, and rats were negative. In stained section the organism resembled *Cryptococcus farciminosus.* (See also the preceding abstract.)

7647. **OHUE, TOSHIO.** On a fungus found in the urine and the cerebrospinal fluid of a patient suffering from meningitis. *Sci. Rept. Tôhoku Imp. Univ. 4th Ser. Biol.* 5(1): 117-132. 3 pl., 2 fig. 1930.—From cultural and pathogenic characters, it seems that the fungus is identical to *Alternaria tenuis* Nees. The very marked and definite changes in the lungs and other organs of inoculated animals are considered sufficient evidence that it was pathogenic to them. Mortality rates were 67% in guinea pigs, 43% in rabbits and 23% in albino rats. The intraperitoneal injection of 0.5 cc. of the filtrate of bouillon cultures was fatal to mice and albino rats. By injection of sterilized culture of this fungus and of living cultures of *Alternaria* sp. collected from leaves of the poppy, no notable disturbance was observed, except slight congestion in various organs. Feeding of spores also caused no particular disturbance. Many spores were found in the urine, lungs, spleen, liver, gall-bladder and brain at varying periods after intraperitoneal and subcutaneous injections. The number of these spores was reduced with lapse of time, and after 1 mo. they were usually not found in any of the organs.—*Author's summary.*

7648. **ONORATO, RAFFAELE.** I micetomi in Tripolitania. [Mycetomas in Tripolitania.] *Arch. Ital. Sci. Med. Coloniale* 7(6): 97-110; (7/8): 137-152. 1926.

7649. **PANEK, K., et M. ZAKCHAROFF.** Pouvoir pathogène des cultures de formes filtrantes du bacille tuberculeux. *Compt. Rend. Soc. Biol.* 106(10): 854-857. 1931.—Using 12 races of the granular form of *Bacillus tuberculosis* obtained from rabbits and guinea pigs infected either with tubercular material or with pure cultures of the human or bovine types, 78 guinea pigs were inoculated and kept for varying periods up to 3 yrs., some being killed at intervals and examined. The pathogenic power of the filterable form is less than that of Koch's bacillus. Inoculated animals show no morbid signs for a long time. After several months, certain animals cease development, lose weight and die in a few weeks; post mortems show more or less extended tubercular lesions and the presence of Koch's bacillus. The pathologic alterations correspond to those of the chronic sclerous form. When the granular form is modified in the body of an inoculated animal into the acid-resistant bacillus form, its virulence is increased in proportion to the number of successive passages through new animals. —*E. Weiner.*

7650. **PEREIRA, Filho.** Sporotrichum fonsecai e o diagnostico differential dos esporotrichados. [Sporotrichum fonsecai and the differential diagnosis of the Sporotricales.] *Rev. Med. Cir. Brasil* 38(5): 163. 1930.—Detailed morphologic and cultural characteristics and analysis of the taxonomic position of the fungus, and numerous illustrations of microscopical and gross appearances are given. It may cause scattered, comparatively deep cutaneous lesions which do not follow the lymphatics as do those of *S. schencki* and *S. beurmanni.*—*F. D. Weidman.*

7651. **PITTMAN, MARGARET, and MERCY A. SOUTHWICK.** Studies on respiratory diseases. XXV. The pathology of pneumococcus infections in mice. *Jour. Bacteriol.* 19(5): 363-374. 1930.—When mice were inoculated with an extract of pneumococci produced by repeatedly freezing and thawing, they developed marked hemorrhagic lesions on all or a part of the external surface free from hair, and at autopsy hemorrhagic areas could be found in practically every tissue. When mice died after inoculation with extract, followed several hours later with a culture inoculation, they had more marked hemorrhagic lesions than any other group of mice studied. Fresh filtrates of virulent pneumococci produced very slight pathological reactions in mice, but, when the filtrates were inoculated with a culture of low virulence, 71% of the mice showed a fibrinopurulent pleuritis at autopsy. Pleuritis was twice as frequent in mice dying from infection with pneumococci that had grown in the presence of salts that lower the P.D. as it was in mice dying from the same strain grown in plain broth. Mice which died or were killed after in-

oculation of pneumococci or pneumococcus products, showed pathological lesions in the lungs, liver, respiratory muscles and possibly in the kidneys. The relation of the extract and filtrates to the pathogenesis of pneumococcus infections is discussed.—*Authors' conclusions.*

7652. **RANKIN, ADAM L. K.** Puerperal infection: a bacteriological study. *Lancet* 219(5578): 188-189. 1930.—The author records the results of bacteriological examination of 89 cases of puerperal infection. A blood culture and a culture from the uterus were taken in each case, and all were incubated under aerobic conditions. In 24 of the 89 cases, hemolytic streptococci were isolated from the uterus in pure culture; in 12 cases they were isolated together with other organisms. The latter included non-hemolytic streptococci, *B. coli*, gonococci, staphylococci and enterococci. In 8 of the cases giving a pure growth of hemolytic streptococci (*Strep. pyogenes*) from the uterus, the same organism was isolated from the blood; 7 of the 8 patients died.—*A. L. K. Rankin.*

7653. **REASONER, MATHEW A.** Experimental yaws and syphilis. *Amer. Jour. Trop. Med.* 9(6): 413-427. 1929.—Experiments with intratesticular inoculation of rabbits with the organisms of yaws and syphilis are reported, only a few animals being used in each. Clear-cut evidence of cross-immunity is shown, but the author thinks that "syphilis and yaws are totally different diseases."—*D. C. Smith.*

7654. **SCHNEIDER, OTTO.** Lepraerinnerungen aus Siam und China. *Arch. Schiffs- u. Tropen-Hyg.* 35(3): 145-159. 1931.—Clinical observations were followed by in vitro culture studies in which pleomorphic bacteria were grown. Experiments with a guinea pig and an anthropoid ape were negative.—*E. C. Faust.*

7655. **SCHUMACHER, C.** Über die Erzeugung von experimentell-luetischen Primäraffekten an der Rückenhaut des Kaninchens und des Meerschweinchens. *Dermatol. Wochenschr.* 89(33): 1210-1213. 1 fig. 1929.—Placing of intracutaneous material seems to be a feasible method of studying experimental syphilis in animals. Rabbits are especially suitable; guinea pigs also may be used; mice do not respond. By this method secondary symptoms may appear. Definite immunity is produced in rabbits against secondary intracutaneous inoculation. The material from one rabbit may be transferred to healthy animals, followed by primary symptoms.—*P. G. Heineman.*

7656. **SECHI, ELIO.** Sulla resistenza in vitro del gonococco e dei comuni germi dell'uretra allo stato normale di fronte ai preparati acridinici (tripaflavina). [In vitro resistance of gonococci and of the common microorganisms of the normal urethra to trypaflavin.] *Gior. Ital. Derm. e Sifil.* 71(5): 1708-1732. 1930.—Resistance in vitro to trypaflavin in various concentrations of 11 urethral microorganisms from 24 normal persons was compared to that of gonococci. The urethral flora was found to vary from one person to another, and from one portion of the urethral canal to another, the anterior portion being frequented by staphylococci and the posterior by streptococci and pseudodiphtheria bacilli. Of the 11 germs found, 8 were Coccaceae, 2 Bacteriaceae, and 1 Coccobacteria. *Staphylococcus albus* showed greatest resistance to trypaflavin (inhibited after the 6th hr. by 1:100,000 solution), and pseudodiphtheria bacilli least (inhibited in the 1st hr. by 1:600,000). Gonococci were among the more resistant organisms (inhibited by 1:200,000).

7657. **SECHI, ELIO.** Influenza reciproca degli estratti (tossine ed endotossine) dei comuni germi della flora uretrale sullo sviluppo proprio e sul gonococco. [Reciprocal influence of the extracts (toxins and endotoxins) of the common germs of the urethra on the development of each other and of the gonococcus.] *Gior. Ital. Derm. e Sifil.* 71(6): 2072-2079. 1930.—Experiments in vitro on 11 microörganisms commonly found in the normal urethra showed that certain exotoxins and endotoxins inhibit growth of certain other organisms, and that gonococci are inhibited by the products of a large number of these normal urethral inhabitants.

7658. **SEITZ, ARTHUR.** Bakteriologie für Zahnärzte: Einführung in die Mikrobiologie und Infektionskrankheiten. [Bacteriology for dentists; introduction to microbiology and infectious diseases.] 2nd ed. v+237p. 7 pl. Walter de Gruyter & Co.: Berlin, 1930. Price 10 M.

7659. **SPAGNOLI, B.** Ricerca della spirocheta nel cervello di paralitici trattati con la malarioterapia. [Attempt to find spirochaetes in the brain of general paralytics treated with malaria.] *Ateneo Parmense* 2(2): 93-98. 1930.—Of 2 general paralytics treated by malaria therapy, the brain of 1 was negative at necropsy; the other showed spirochaetes in the frontal cortex.

7660. **WEINBERG, M., et N. COMBIESCO.** Lésions hémorragiques causées par le B. perfringens. *Ann. Inst. Pasteur [Paris]* 45(5): 547-580. 20 fig. 1930.—The authors report intravenous injection of various doses of *Bacillus perfringens* into a series of 10 guinea pigs, and refer to a supplementary series of 5. Severe hemoglobinuria, hematuria, congestion and pigmentation of various organs, and hemorrhagic and necrotic foci were among the necropsy findings. In some cases small doses produced more severe lesions than doses 2.3 times larger produced in other guinea pigs, indicating marked difference in individual resistance. The intensity of congestion of the organs was not always in proportion to depth of pigmentation. It is concluded that *B. perfringens* produces 2 toxins, one an active hemolysin, the other producing necrosis of the vessels.

7661. **ZANZUCCHI, A.** Contributo sperimentale sul passaggio nel circolo sanguigno dei batteri a sede intestinale. [Passage of intestinal bacteria into the circulation.] *Ateneo Parmense* 2(5): 393-399. 1930.—To learn whether protracted intestinal contraction causes intestinal bacteria to enter the circulating blood, the author induced peristalsis in 8 dogs by injection of various drugs and meanwhile made cultures from the blood. All results were negative.

7662. **ZDANSKY, ERICH.** Über vergleichende Keimzahlbestimmungen im arteriellen und venösen Blute bei Endocarditis lenta. *Zeitschr. Ges. Exp. Med.* 76(3/4): 571-576. 1931.—In 10 cases of endocarditis lenta, 9 of 19 comparative bacterial counts of blood from the brachial artery and from a vein in the elbow showed a higher count in the artery; 9 showed similar counts; 1, lower in the artery than in the vein. The decrease in bacteria from artery to vein may be traced to the imprisoning and destroying action of the capillaries; the decrease was called the bacteria count deficit (expressed in terms of arterial count) and never exceeded 50%. It may be of value in estimating the defense reaction of the body.

7663. **ZDRODOWSKI, P., H. BRENN, et B. VOSKRESSENSKI.** Étude sur la fièvre ondulante en Azerbaidjan. Recherches spéciales sur le groupe Brucella melitensis-abortus. *Ann. Inst. Pasteur [Paris]* 45(6): 768-805. 1930.—Human infection in Azerbaijan runs parallel to infection in sheep and goats, especially the former. Contagious abortion is apparently not widespread among cattle there, though serologically the Azerbaijan strains of *Br. melitensis* are closely allied to *Br. abortus*. The authors studied 64 strains of Brucella of human and animal origin, from various countries. *Br. abortus* could not be distinguished from *Br. melitensis* by pathogenicity for guinea pigs, nor could human strains of *Br. abortus* be thus distinguished from strains of animal origin. *Br. paramelitensis* (6 strains, all "R" type) proved entirely avirulent for guinea pigs. Cultures of the "S" type were in general (29 of 31 strains) very virulent. All *Br. paramelitensis* cultures were of R type; this type was not found in 26 original cultures of human and bovine *Br. abortus*. Intermediary types between "S" and "R" were observed. Some "S" strains were stable; these were strains of *Br. abortus* and *Br. melitensis*, properly speaking. Others were labile, tending toward type R; these were strains of *Br. paraabortus*

and *Br. paramelitensis*. Serologically, some strains of *Br. melitensis* were differentiated from *Br. abortus;* others were not. This serologically non-differentiated type of *Br. melitensis* was the rule in Azerbaijan, although sheep and goats are the chief reservoir for human infection. Typical strains of *Br. paramelitensis* and *Br. paraabortus* were serologically clearly differentiated, but a labile strain of *Br. melitensis* or *Br. abortus*, assuming the "para" characteristics, would acquire also the serological peculiarities appertaining thereto. The authors believe that Evans' proposal to classify the Brucellas by serologic characters is arbitrary.

7664. **ANDO, K., K. KURAUCHI, and H. NISHIMURA. A new plague endemic area in the northeastern part of inner Mongolia. Plague studies I.** *Kitasato Arch. Exp. Med.* 8(1): 24-38. 1 map. 1931.—Considering the data as a whole, it seems justified to conclude that the animal playing the leading rôle in this plague epidemic in the new area might have been susliks (*Citellus mongolicus umbratus*); rats, though prevalent everywhere, seem to have taken no significant part in this epidemic and most of the infections seem to have been carried by the natives themselves.—*Authors' conclusion.*

7665. **BIJL, J. P., und G. KORTHOF. Über das Vorkommen der Weilschen Infektion in Holland während der Jahre 1924-1930.** *Arch. Hyg. u. Bakt.* 105(1): 29-34. 1 map. 1931.—About 20 cases occurred in Holland yearly, particularly in the areas where water is abundant. Patients' sera, in great dilution, would agglutinate or dissolve *Leptospira icterohaemorrhagiae* early in the disease. Contact with water (particularly some canals) was a special source of infection; 20% of rats were infected (37 of 167 examined). Epidemics of jaundice not showing signs of Weil's disease were negative bacteriologically and serologically.—*Authors' summary (transl.).*

7666. **BROMBERG, I. M., and R. COMAROFF. Epidemiology of typhoid fever. Incidence of typhoid carriers in a general population group.** *Jour. Hyg.* 29(2): 139-145. 1929.—In examining 869 specimens, the authors found 3 typhoid carriers among 484 inhabitants of Afule, Palestine. For this study, based on preliminary experiments, brilliant-green glycerin solution was adopted as the shipping fluid and brilliant-green-MacConkey agar as the plating medium. Since zinc loops were unsatisfactory because of the dissolving action of the shipping fluid, steel loops were used in the stoppers of the collecting bottles.—*G. E. Harmon.*

7667. **DOWNHAM, K. D. The examination of milk for the presence of tubercle bacilli.—A comparison between the cell group method and a method for the concentration of tubercle bacilli in milk.** *Vet. Rec.* 11(29): 756-758. 1931. —In 24 of 31 samples examined, tubercle bacilli were found more quickly by the cell-group method than by the concentration method. In 3 samples the latter proved more rapid; in 4, there was no appreciable difference. Preparation of a milk smear by the concentration method required 5½-6 hrs.; by the cell-group method, 20 min. Possibly the concentration method may be of value in examining milk from cows with tuberculous mastitis, which have suffered from other conditions of the mammary gland masking the tuberculosis lesions.—*Author's conclusion.*

7673. **FUCHS, A. W., and H. A. KROEZE. Results of the operation of the standard milk ordinance in Mississippi.** [*U. S.*] *Publ. Health Repts.* 45(25): 1412-1421. 1930.—Excellent results were obtained after but 2 yrs.' experience with the standard milk ordinance recommended by the U. S. Public Health Service. By the end of 1929 there were 26 cities, containing over 75% of the State's urban population, enjoying a high-grade protection of their milk supplies, as against 6 cities formerly. Improvement in sanitary quality has been satisfactory. The rating of retail raw milk has improved 91%; of raw milk for pasteurization, 89%; and of pasteurization plants, 109%. Milk consumption has increased 23%. The number of cities having pasteurized milk has doubled, and the consumption of pasteurized milk has risen 117%. —*A. W. Fuchs.*

7674. **FRENKEL, H. S., en A. CLARENBURG. Bacillus suipestifer als oorzaak van vleeschvergiftiging.** [*B. suipestifer as cause of meat poisoning.*] [With German, English & French summaries.] *Tijdschr. Diergeneesk.* 58(6): 299-307. 1931.—An epidemic of meat-poisoning (acute gastro-enteritis) following ingestion of meat from a diseased pig is reported. From several pieces of salted and smoke-dried meat, paratyphoid B bacteria were cultivated, which culturally and serologically were dedetermined to be *B. suipestifer*. Bacteriological examination of the feces of one of the patients for paratyphoid bacteria was negative. The blood serum of one of the patients gave positive agglutination with *B. suipestifer* at 1:400. Contrary to the opinion of Uhlenhuth, *B. suipestifer* is to be considered as pathogenic to man.—*Authors' summary.*

7675. **HUSS, R., und K. ÖSTLING. Einige Erfahrungen betreffs Schicks Reaktion.** *Acta Med. Scandinavica* 70(5/6): 535-543. 1929.—In the beginning of the first year, the number of Schick-positive reactions is greatest; then, however, the trend is a decreasing one. It was found that the number of Schick-positives among active bacillus carriers is relatively lower than in non-bacillus carriers. That the pseudoreaction is an allergic one is in accordance with the findings. By use of the Schick test it has been determined that an epidemic is impossible through milk infection. Any definite answer

to the question concerning the spread of an epidemic is, however, not determinable by this means.—*K. C. Berthelsen.*

7676. KADISCH, E. Die Hitzeresistenz einiger Hefen. *Dermatol. Zeitschr.* 60(1/2): 48-51. 1930.—*Monilia tropicalis*, 4 strains of *M. albicans*, *Cryptococcus rubro-rugosus*, *Coccidioides immitis* and *Schizosaccharomyces hominis* were tested at 56°, 60°, and, in the case of the latter organism, at 70° C., over intervals of 3 min. to 3 hrs. The author concludes that the resistance for these yeast-like fungi is about the same as for hyphomycetes hitherto tested; only when relatively dry do they become more heat resistant. In general, 60° C. for 10 min. suffices. Benedek's Schizosaccharomyces was extremely resistant. Hence, present-day "lukewarm" laundering technique does not disinfect.—*F. D. Weidman.*

7677. KURAUCHI, K. The rodents of inner Mongolia. Plague studies. II. *Kitasato Arch. Exp. Med.* 8(1): 39-43. 1 pl. 1931.—Among 57,216 small mammals purchased in Cheng-chiatun were found: 48,328 mice, 8,741 wild rodents, 82 *Allactaga* (jumping hare), 27 mole-rats, and 37 hedgehogs. The majority of the mice were *Mus wagneri manchu;* only a few, *R. alexandrinus* and *R. norvegicus;* and none, *R. rattus.* Of the Sciuridae, only suslik (*Citellus*) was found. In South Russia, recently also in Transbaikalia, *Allactaga* is regarded as one of the reservoirs of human plague.—*Author's summary.*

7678. MONTGOMERY, B. E. The bactericidal power of viosterol. *Proc. Soc. Exp. Biol. & Med.* 28(5): 481. 1931.—Irradiated ergosterol (viosterol) in solution in corn oil was added to agar in various quantities, and compared with corn oil added to agar in the same concentrations; *Bacillus coli* and *Staphylococcus aureus* seeded on plates of such media showed no modification or inhibition of growth as compared with growth on plain agar controls.

7679. NITTA, Y. Die Wirkung von Farbstoffen auf Gonokokken in vitro und in vivo. *Zeitschr. Hyg. u. Infektionskr.* 111(1): 68-78. 1930.—The bactericidal action of various stains on gonococci was tested in test-tubes and in the abdominal cavity of white mice. None of those tried equalled the acridin stains. Those investigated and found entirely without action were the pyrazol, monazo and diazo, anthraoxyphthalein, diphenylnaphthylmethane, thiobenzenyl, chinoxalin, indulin and sulphur groups of dyes. Those found to act weakly were the oxyphthalein, oxazin, eurhodin, rosindulin and isorosindulin groups. Some members of the triphenylmethane and benzosafranin groups were efficient. Among the latter, distinct differences often occurred between bactericidal action against gonococci in vitro and in vivo.—*Author's summary (transl. by C. E. Gabel).*

7680. POE, CHARLES F. Differential tests for the colon-aerogenes groups. *Jour. Amer. Water Works Assoc.* 23(8): 1218-1226. 1931.—Over 350 organisms of these groups, representing a very wide distribution, were studied. Correlation of the uric-acid with the Voges-Proskauer and methyl red tests was unsatisfactory for the colon group. Correlation of the sodium-citrate with the Voges-Proskauer and methyl red tests was almost perfect for the aerogenes group and 77% perfect for the colon group. Eosine-methylene blue agar medium is excellent to differentiate the colon from the aerogenes group. There were a number of organisms for which the Voges-Proskauer and methyl red tests could not be made to correlate.—*Author's conclusions.*

7681. RAAB, FRANK. Taste and odor troubles in the Minneapolis water supply. *Jour. Amer. Water Works Assoc.* 23(3): 430-434. 1931.—Chlorine-ammonia treatment failed to remove moldy odor from the Minneapolis water supply. Pre-chlorination practically removed it, increased the filter runs from an average of 8 to an average of 28 hrs., and completely eliminated anaerobic gas fermentation in the finished water.—*Author's summary.*

7682. SINGER, ERNST. Die bakteriologische Untersuchung des Trinkwassers. [Bacteriological investigation of drinking water.] iii + 96p. Gustav Fischer: Jena, 1931. Price 5 M.

7683. STREETER, H. W., and C. T. WRIGHT. Prechlorination in relation to the efficiency of water filtration processes. *Jour. Amer. Water Works Assoc.* 23(1): 22-53. 1931.—From parallel experiments in rapid-sand water filtration, with and without raw water prechlorination, it was shown that a consistent improvement in quality of final effluent is obtained with prechlorination, though the efficiency of filtration and of post-filter chlorination is measurably reduced. Best results were obtained by prechlorination before sedimentation, with a residual Cl content of 0.05 p.p.m. or less after 6 hrs. of sedimentation and just prior to filtration. The bacterial content and biochemical oxygen demand of the filter sand were lowered by prechlorination.—*H. W. Streeter.*

7684. STREETER, H. W. Experimental studies of water purification. IV. Observations on the effects of certain modifications in coagulation-sedimentation on the bacterial efficiency of preliminary water treatment in connection with rapid sand filtration. [*U. S.*] *Public Health Repts.* 45(27): 1521-1571; (28): 1597-1655. 1930.—Observations with periods of sedimentation of 3-12 hrs. following coagulation indicated that bacterial efficiency is increased considerably with periods up to 8-9 hrs. and to a lesser extent up to 12 hrs. Double-stage coagulation-sedimentation showed no gain in efficiency over single-stage treatment, with similar dosages of coagulant and periods of sedimentation. The efficiency of coagulation was not affected materially by variations in pH of 5.6-6.9, but fell off decidedly with pH values greater than 6.9. A fairly consistent relation was shown between dosage of coagulant and resulting bacterial efficiency.—*H. W. Streeter.*

7685. THAYSEN, A. C., and L. H. WILLIAMS. On the bactericidal properties of ether, alcohol, chloroform and carbon bisulphide. *Zentralbl. Bakt. 2. Abt.* 84(8/14): 252-260. 1931.—Experiments on the efficacy of Wollney's method of sterilization by immersion in ether showed the method to be effective, but the prolonged time required for complete sterilization of wholemeal wheat flour caused drastic changes in chemical composition of such flour and for this reason the method is unsuitable. If the substance to be sterilized is first immersed in ether long enough to destroy non-spore-forming microorganisms (48 hrs.), then treated in such a way that spores may germinate, and finally immersed for a 2nd short time in ether, a method for sterilization of heat-labile substances is evolved, which is comparatively harmless to the protein of wholemeal wheat flour but effective in destroying all microorganisms. CS_2 and $CHCl_3$ were found inferior to ether for sterilization of thermolabile substances such as wheat flour.—*From authors' conclusions.*

7686. TONNEY, FRED O., and RALPH E. NOBLE. An improved ferrocyanide-citrate agar for direct enumeration of colon-aerogenes oganisms. *Jour. Amer. Water Works Assoc.* 23(8): 1202-1208. 1931.—With the changes in preparation and technic here described, cyanide-citrate agar now possesses advantages of simplicity and improved productivity over the medium as originally reported. The average number of colon-aerogenes colonies produced equals or slightly exceeds the corresponding plain nutrient agar counts made from the same titered suspensions. Immediately before use, 2 solutions containing the essential ingredients are added to the melted agar, and the medium is ready for plating. The basic fuchsin is now standardized by arrangement with the manufacturer. An illuminated chamber affording suitable lighting conditions to differentiate and count colon-aerogenes colonies, is described.—*Authors' summary.*

7687. TSCHURILINA, A. A. Epidemiologische Untersuchungen über die Pest. *Zeitschr. Hyg. u. Infektionskr.* 111(2): 198-209. 1930.—Bubonic plague was apparently kept going in Saratoff, Astrakhan and the Don provinces by ground squirrels ("Zieselmäusern"), though no cases

were found in other rodents. The organisms were identical with those of human plague. The possibility of flea transmission from ground squirrels to field mice was demonstrated experimentally. Ground squirrels infected in hibernation showed a slow chronic type of infection lasting as long as 5 mo.—*R. G. Perkins.*

7688. WALTHER, KARL. Züchtungsergebnisse und Abtötungsversuche mit dem Hohnschen Schwefelsäureverfahren. *Zentralbl. Bakt. I. Abt. Orig.* 115(3/4): 235-240. 1929.—In 17 cases where tubercle bacilli were demonstrable in the stained sputum preparation, positive cultures were obtained. In 80 cases with doubtful sputum findings, tubercle bacilli were demonstrated 4 times with antiformin and 13 times by the Hohn culture technique (digestion with 12% H_2SO_4 and culture on egg medium enriched with hematin). The Hohn method in general gives a quicker answer than animal inoculation. H_2SO_4 kills smegma, timothy hay, and similar bacilli, but does not kill "trumpeter bacilli" (found by Jacobitz and Kayser in the saliva of wind instrument musicians and in their horns). In cases whose history indicates the possible presence of these organisms, animal inoculation must be used.—*H. F. Smyth.*

7689. WOODWARD, F. L. Pollution studies of the upper Mississippi River. *Indust. & Eng. Chem.* 22(2): 189-192. Map. 1930.—Activities of the Minnesota State Board of Health and co-operating departments, in studying the pollution problem of the Mississippi River from Minneapolis and St. Paul, Minnesota, to La Crosse, Wisconsin (160 miles), are considered. During the winter, marked pollution was found as far as the outlet of Lake Pepin, about 160 miles, while during summer, pollution was in evidence at the head of the Lake, 70 miles below Minneapolis. Oxygen balance, i.e., dissolved O minus the 5-day biochemical O demand, is shown in charts, as are also total bacteria and coli-aerogenes per cc. for a 6-mo. period. During summer, odors are produced in the pool above Twin City Lock and Dam. Another dam is being constructed at Hastings, 30 miles down-stream, which is expected to bring about similar conditions in St. Paul and So. St. Paul.—*C. M. Hilliard.*

7690. ANONYMOUS. 1930 bacteriological examination of water. *North Dakota Office State Food Comm. & Chem. Bull.* 30. 62-65. 1931.—A list of 158 samples analyzed during the year, giving the laboratory report on each.

(See also in this issue Entries 6529, 6532, 6562, 6573, 6576, 6578, 6579, 6596, 7674, 7685, 7742, 7766)

7691. BISHOP, L. R. The practical application of the results of research to the production of malt and wort. *Jour. Inst. Brewing* 37(7): 345-359. 1931.—Under normal English malting and standard mashing conditions the total "permanently soluble" N (p.s.n.) of the wort is, for 2-rowed barleys, about 33-35% of the original barley N. For 6-rowed barleys the corresponding figure is 28-29%. The % increases with increasing "modification" during malting, and vice versa. Amino, amide, peptide and residual "undetermined" N were estimated in the wort. The composition of the p.s.n. is fairly regular, and the increase with increasing total barley N is due mainly to increase in the "peptide" and "undetermined" N groups. The optimum mashing temp. for production of p.s.n. is 50° C. and this is due to an optimum production of peptide N at this temp. The optimum mashing temp. for maltose production is sharply defined at 60°; that for dextrin production is above 70°. The manner in which such results can be utilized in practice is foreshadowed.—*L. R. Bishop.*

7692. BODNÁR, J., und LADISLAUS BARTA. Zur Frage nach der Zersetzung von Nicotin im Tabak durch Bakterien. *Biochem. Zeitschr.* 233(4/6): 311-315. 1931.—According to the nicotine content, 2-5 gm. samples of tobacco with 5 times as much water were kept at 30° C., and nicotine and ammonia determined in the autolysate; the suspensions began to decompose on the 2nd day; on the 9th day there had been no reduction in nicotine. Samples allowed to dry in the air, after 4 days (antiseptics being added) showed little decrease in nicotine and that due to volatilization. Samples autolyzed with 1% glucose (some dried) showed no loss except that due to volatilization. Ammonia was the only volatile, basic product of decomposition present in more than insignificant traces. If nicotine under some circumstances should break down in the course of tobacco decomposition, the process would be very different from that occurring during fermentation.

7693. DIEUZEIDE, R., et A. ARGILAS. Essais de conservation temporaire de crustacés et de sardines. [Experiments in temporary preservation of crustaceans and sardines.] *Bull. des Trav. Publ. Stat. Agric. et Pêche de Castiglione* 1928(2): 115-125. 1 fig. 1928.—Temporary preservation of *Parapenaeus membranaceus* in sealed containers by sterilization in an autoclave, in brine composed of a 12% NaCl solution, gave the best practical results. Sale of the product is enhanced by artificial coloring with carmine. Another No. African crawfish, *Aristeus antennatus*, is not well adapted for temporary preservation. Sardines may be successfully preserved by frying in oil, covering with "Scabetche" sauce, and sterilizing in an autoclave in sealed containers. The frying could be replaced by drying in the sun or in an oven.

7694. FELLERS, CARL R. Pasteurized dried fruits. *Amer. Jour. Public Health* 20(2): 175-181. 1930.—The author found the number of organisms on dried fruits variable, being lowest in sulphured, somewhat higher in pasteurized, and highest in raw fruits. Of bacteria, anaerobes occurred in over ½ the samples; cocci were relatively abundant. Of 79 samples examined, only 8 showed lactose fermenters; none were *Escherichia coli* and several were probably *Aerobacter aerogenes*. Molds often outnumbered bacteria. *Aspergillus* was commonest; its spores often survived effective pasteurization. In 60 of the samples, yeasts failed to develop on nutrient agar. Dates, raisins, prunes and figs may be pasteurized without injury. Laboratory tests of various dried fruits proved that with humidities of 70-100% and holding for 30-90 min., temp. of 160-185° F. in the fruit are effective. *Escherichia coli* and *Eberthella typhi* were the test organisms used. Acid fruits, with their lower pH, may be pasteurized at lower temp.—*H. N. Parker.*

7695. FRENCH, J. M. Notes on the colorimetric method for determination of the preservative value of hops. *Jour. Inst. Brewing* 37(8): 436-439. 1931.—A simplified method for colorimetric determination of the preservative value of hops, based on that of Guthrie and Philip, is described. It gives practically identical results with those obtained by the original method, with economy in time and materials. Various grades of pure alcohol and industrial methylated spirit may be used without lack of accuracy, provided that standards are made up with the same alcohol. Solutions of ferric chloride are proposed for making up a series of standard solutions, based on an original series made with humulin. Owing to changes in the hop extract and in the colored solutions, all determinations must be made as rapidly as possible after extraction. The uranium salt solution must be kept in amber bottles.—*Author's summary.*

7697. LEA, COLIN H. Chemical changes in the fat of frozen and chilled meat. Part I. Frozen mutton and

lamb. *Chem. & Indust.* 50(25): 207T-213T. 1931.—Free acidity changes were comparatively slight, the maximum being 1.2% (as oleic acid) for external fat and somewhat less for kidney fat. In no case were signs of superficial oxidation of the fat observed during 24 hrs. precooling at ordinary temp., and no definite increase in susceptibility to oxidation during subsequent storage could be detected as a result of precooling treatment. Oxidation of the fat of carcasses held at −5° C. up to 7 mo. was very slight, and in no case did oxidation occur sufficiently to affect the flavor of the fat, when such carcasses were held for 3 days at ordinary temp. in not too powerful light. The effect of comparatively long periods of sweating on the free acid content of the fat was very small; on the other hand, sweating in presence of light exerts a deleterious effect on the keeping properties of the fat when held subsequently at ordinary temp. A storage at −5° failed to prevent growth of molds and yeasts, but no visible growth occurred at −10 or −20°.—*From author's conclusions.*

[Histologic differentiation of sausage constituents and of contained microorganisms.** *Rev. Higiene y Sanidad Pecuarias [Madrid]* 21(7/8): 439-450. 1931.—Methods of embedding, sectioning, and study are discussed.

7699. **MARVIN, GEORGE E. The occurrence and characteristics of certain yeasts found in fermenting honey.** *Biologist [Denver]* 10(1): 65-69. 2 pl. 1928.—5 apparently different types of yeasts were isolated from 4 samples of fermenting honey, by methods described. They all fermented glucose, levulose and mannose. Only 2 fermented sucrose and one of these also fermented maltose. Honey brought to 160° F. will resist fermentation as well as unheated honey stored below 52° F.

7700. **PORCHET, BERTHE. Contribution à l'étude de l'adaptation des levures à l'acide sulfureux.** *Ann. Agric. Suisse* 32(2): 135-154. 1931.—*Saccharomyces ellipsoideus* by numerous cultural passages in sulphurated must became adapted to cultures containing 0.3-0.4 gm. of K-metabisulphite per liter, an amount preventing multiplication of non-adapted yeasts. This character is transmitted; and adapted yeasts cultivated for several mo. on ordinary must have preserved their resistance to SO_2 for 200-350 generations. In the course of following generations the resistance weakened and disappeared. —*From author's summary (transl.).*

7701. **SAILER, LEONHARD. Beiträge zur Lösung des Problems der deckenlosen Gärung.** *Wochenschr. Brauerei* 48(13): 129-133; also in *Zeitschr. Ges. Brauwesen* 1931 (9): 72. 1931.—A description of a device for both clarifying and cooling the fermenting wort, consisting of a grid of flat pipes, of boat-shaped cross-section, connected to the cooling water supply and removable from the vat. The grid is partly immersed in the fermenting wort, and the scum borne up by the foam is deposited on, and adheres to, the exposed surfaces of the flat pipes; after fermentation is over the device may be removed and the accumulated deposit washed off.—*F. A. McDermott.*

7702. **SCHMID, WILLI. Einfluss von Temperatur und Feuchtigkeit auf das Bakterienwachstum auf gekühltem Fleisch.** *Zeitschr. Ges. Kälteindustrie, Beih.* 3(6): 1-30. 15 fig. 1931.—Within certain limits, lowering the temp. 1° increases the relative humidity about 5%. The concept that meat is a favorable nutrient medium for bacteria only above the dew point is erroneous. The development of bacteria varies more nearly exponentially with the relative humidity. Since bacteria develop well in a relative humidity of 90-100%, this degree of humidity should be avoided in refrigerators.—*From author's summary (transl.).*

7703. **SCHOEN, M. Les bases scientifiques de quelques nouvelles industries de fermentation.** *Chim. et Indust.* 25(3 bis): 96-110. 1931.—The author gives the history of the discovery of the acetone-butyl-alcohol fermentation and its theoretical basis. Observations on the mechanism of the simultaneous production of acetone and butyl alcohol are included. The 2nd part of this work is a general review of citric fermentation. This is regarded as a result of an incomplete oxidation of sugar by *Aspergillus niger.—M. Schoen (transl. by C. S. Pederson).*

7704. **SCHÖNBERG, F. Über die Fischfäulnis und ihre bakteriologische Diagnose.** *Berliner Tierärztl. Wochenschr.* 46(27): 429-435. 1930.—The bacterial content of decomposed fish is always high; it is large even in slight decomposition. The most important bacteria are gram-negative, slender, very motile rods which liquefy gelatin and grow best at room temp. Of secondary importance are the gram-positive micrococci, *Proteus,* colon bacilli and *B. mesentericus.* Anaerobes play a subordinate rôle. The organisms isolated produced decomposition in a short time when inoculated into fresh fish muscle.—*Author's summary (transl. by G. de Bord).*

7705. **SÉBASTIAN, V. Quelques réflexions et observations sur la levure apiculée objectif de la "superquatre."** *Progr. Agric. et Vit.* 93(24): 572-578. 1930.—The author discusses the characters of *Saccharomyces apiculatus,* commonly found in early wine fermentations, pointing out particularly its lower resistance to heat, to alcohol and to H_2SO_3, as compared to the ordinary *S. ellipsoideus.* Its sensitivity to H_2SO_3 is considered of great importance, in that it may be used at the rate of 10-15 gm. per hectoliter in fruit juices, to suppress growth of *S. apiculatus,* which is always present, without inhibiting growth of the selected yeast.—*C. S. Pederson.*

7706. **TRACY, R. L., Jr. Sterilization of fruit juice by electricity.** *Fruit Prod. & Amer. Vinegar Indust.* 10(9): 269-271. 1 fig. 1931.—Experiments are described which indicate that very probably electricity possesses germicidal properties, and that this property is no doubt a factor in sterilization by electricity. It has been shown also that electricity is an effective means for pasteurization of fruit juices when the lethal temp. of the contaminating organisms is maintained.—*Author's summary.*

(See also in B. A. 6(2): Entries 4224, 4476, 4478, 4500, 4567, 4759; and in this issue 7395, 7667, 7673, 7876)

7709. **BARKWORTH, H. The keeping quality of afternoon milk.** *Jour. So.-Eastern Agric. Coll. Wye, Kent* 28. 270-272. 1931.—Afternoon milk samples do not keep sweet as long as morning samples with the same total count. The difference on the basis of similar count is 9 hrs. Possible causes are examined. At least in part,

the loss is actual, due to factors not yet determined, but possibly connected with the uneven interval of milking time.—*Author's summary.*

7710. **BARKWORTH, H. Normal variations of keeping quality.** *Jour. So.-Eastern Agric. Coll. Wye, Kent* 28. 273-277. 1931.—From data presented it is deduced that while keeping quality of milk cannot be used as an indicator of total count, a given total count is associable with a keeping quality which varies by 20%, corresponding to a total range of variation of approximately 1 day.—*From author's summary.*

7711. **DAHLBERG, A. C., and J. C. MARQUARDT. The creaming of milk pasteurized at high temperatures.** *New York State [Geneva] Agric. Exp. Sta. Bull.* 180. 1-26. 4 fig. 1931.—Report of a study to establish the relationship of high temp. pasteurization to the time that milk can be held hot before its creaming properties are impaired. The temp. studied were 150°-165° F.; the holding periods, less than 10 sec. to more than 5 min. Milk exhibited an irregular heat induction period, i.e., a period of varying time at which it could be held before creaming was impaired. There was considerable variation in total time required for milk to pass through the heating tubes and in time that milk was held above certain temp. during heating. These factors need to be considered in pasteurization of milk at high temp. Impaired creaming properties were most evident and differences generally greatest in the 2- and 4-hr. readings. Reduced cream layer volumes were caused by failure of the fat to rise into the cream layers.—*A. C. Dahlberg.*

7712. **FRAYER, J. M. The production of high quality milk. II. The influence of delayed cooling upon the quality of milk.** *Vermont Agric. Exp. Sta. Bull.* 313. 1-34. 17 fig. 1930.—The author found prompt cooling of milk to 50° F. or less necessary to obtain good milk with high keeping quality. Injury to milk quality was roughly proportional to length of time elapsing before cooling. Injury to quality due to delayed cooling was not always noticeable when the milk was received at the country plant, although the methylene blue test was apparently more sensitive to these differences in fresh milk than the plate count.—*H. W. Marston (courtesy Exp. Sta. Rec.).*

7713. **HARDING, HARRY A., and ARCHIBALD R. WARD. Observations on effects of thermophilic bacteria in pasteurized milk.** *Ann. Rept. Internat. Assoc. Dairy and Milk Inspect.* 19: 135-143. 1930.—Observations are reported on the methylene blue reductase test of pasteurized milk at 145° F. instead of 100° F. The reduction times of milk before and after heating and holding for 30 min. or longer were compared. In 28 comparisons, the reduction time of milk held at pasteurizing temp. for 30 min. or more was lessened, and the longer the holding time the more pronounced the lessening. Most of the observations concerned milk pasteurized by the holding process in coil vats or glass lined tanks. 2 observations were made on the milk treated by an electric flash pasteurizer, and a slight shortening of the reduction time was observed after operating periods of 80 and 140 min., respectively. The shortening of the reduction time of milk by pasteurization is attributed to the activity of thermophilic bacteria.—*H. A. Harding.*

7714. **HERNS, FRANK. The septic tank method of disposing of cheese factory and creamery waste water.** *Ontario Dept. Agric. Bull.* 361. 81-83. 1930.

7715. **HOOD, E. G., and A. H. WHITE. Rancid flavour in Cheddar cheese.** *Canada Dept. Agric. Bull.* 146. 1-16. 1931.—During 1930, 0.85% of all cheeses graded in Ontario and 1.4% of all cheeses graded in Quebec were rancid or slightly rancid. Through introduction of undesirable bacteria into the cheese milk, typical rancid flavors were produced in experimental cheese. Butyric acid or rancid-producing bacteria in the milk are due to unsanitary conditions. Rancid flavors have never been found in cheese where the quality of the milk was right and good conditions of sanitation prevailed. A survey of troubled factories showed that much of the equipment was not properly sterilized and that many of the factory starters were inactive and highly contaminated with molds, yeasts and undesirable bacteria.—*Authors' summary.*

7716. **ILZHÖFER, HERMANN. Über den Nachweis stattgehabter Erhitzung der Milch.** *Arch. Hyg. u. Bakt.* 105(6): 319-321. 1931.—A color test is given by which previous heating of milk for ½ hr. to 63-65°, to 70°, to 75°, and for 1-2 min. to 83-85°, can be detected.

7717. **JOHNS, C. K. Farm sterilization of dairy utensils by hypochlorite.** *Ann. Rept. Internat. Assoc. Dairy & Milk Inspect.* 19: 236-244. 1930.—Furnishing of hypochlorite to 39 average farmers, with instructions for rinsing utensils, resulted in marked reduction in bacterial content of milk, as compared with results from previous control samples.—*C. K. Johns.*

7718. **JOHNS, C. K. The destruction of ropy and bitter milk organisms by hypochlorite.** *Scientific Agric.* 12(1): 38-42. 1931.—Relative efficiency of solutions of 3 hypochlorite products in the destruction of 5 ropy and 2 bitter milk organisms was studied. The less alkaline hypochlorites proved extremely effective against all 7 test organisms. Against the more alkaline product, however, the gram-positive spp. exhibited varying degrees of resistance. No marked differences in stability occurred in concentrated products stored at room temp. for 6 mo. —*Author's summary.*

7719. **KOCH, SVEND O. Sterilisation af Mælkeflasker. [Sterilization of milk bottles.]** *Maanedskr. Dyrlaeger. [Copenhagen]* 42(9): 231-235. 1 fig. 1930.—The usual mechanical methods of cleaning milk bottles in small dairies leave great numbers of bacteria. However, investigations have shown that bottles can be sterilized efficiently in zinc containers under steam for 10 min.—*S. O. Koch.*

7720. **KOHN, F. G., und E. KELMM. Die Schern-Gorlische Ringreaktion zur Unterscheidung von roher und erhitzter Milch.** *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39(1/2): 82-93. 1931.—The test is recommended for control of pasteurization of milk and for identification of market milk which has been heated. The technique used is to prepare a suspension of red blood cells or animal charcoal in 0.5 and 1.0% suspensions in physiological saline. To 1 cc. of milk add a drop of the suspension, shake to mix thoroughly, and hold at 38° C. for 2 hrs. At the end of the period, raw milk had a heavy ring of this substance in the cream and a slightly colored sediment on the bottom of the tube, while pasteurized milk showed a slight ring in the cream and a much heavier sediment of the suspended material. Freezing or watering the milk did not affect the reaction. —*L. D. Bushnell.*

7721. **LERNER, M. Een colititer voor melk. [Coli titration of milk.]** [With German summary.] *Nederlandsch Tijdschr. Hyg. Microbiol. en Serol.* 6(2): 81-97. 1931.—Gersbach's indol test for water was used for milk. Controls show that with positive results, *B. coli* is always present. The dilution which still gives a positive indol reaction is a measure of the content of *B. coli* and of fecal impurities. It is easy to get milk from farms that shows the indol reaction when diluted 1/1000 cc.; in "hygienic" or model milk plants milk can be obtained that in the 1/100 cc. dilution still gives a negative indol reaction. The "Pegallac" method for determining *B. coli* is unsatisfactory. It often gives positive results when *B. coli* is absent and the gas formed is almost independent of the original number of *B. coli* present.—*Author's summary (transl.).*

7722. **PRICE, F. E. Cream and milk refrigerator experiments.** *Agric. Engin.* 11(1): 33-37. 1930.—Bacterial count, flavor, odor, and acidity were the basis of comparison between the following methods of cooling and storage of cream: (1) a 50° and 60° water tank changed twice daily; (2) a refrigerator box cooled by ice; (3) a refrigerator box cooled by mechanical-unit, dry-method, natural-baffle circulation; (4) a refrigerator box cooled by mechanical-unit, wet method; (5) a refrigerator box cooled by mechanical-unit, dry method, using a fan for forced circulation. Results for a 90 hr. period indi-

cate that bacterial growth was entirely stopped by the 4th method and effectively retarded by the 5th. The first 3 types of cooling allowed excessive bacterial growth but, with the exception of the 60° water tank method, all the cream graded as "1 sour." Temp. measurements were made with Cu-constantan thermo-couples and a type P Leeds-Northrop galvanometer. The wet methods were more rapid than the dry for cooling the cream. Results indicate that circulation of air within the refrigerated box had more influence on cooling the cream than stirring the cream in the cans. Experiments with the cooling and storage of milk in a dry box cooled with expansion cells, in refrigerated water, and in refrigerated water that was agitated indicated, as with the cream, that cooled or refrigerated water is more effective for rapid cooling. However, where precooling was used, dry refrigeration was satisfactory. Agitated water provided more rapid cooling conditions than the non-agitated. Any differences in bacterial counts due to these 3 methods were within the limits of error.—*L. A. Burkey.*

7723. **ROBERTSON, A. H., and J. M. FRAYER. Variability, accuracy, and adaptability of some common methods of determining the keeping quality of milk. I. Methods of comparison.** *Vermont Agric. Exp. Sta. Bull.* 314. 1-46. 12 fig. 1930.—The advantages of certain methods of determining the bacterial content of milk are considered. Conclusions are based on results obtained with 268 samples of milk analyzed by the reductase test and by actual agar plate counts. The geometric mean more nearly approached a satisfactory average than the arithmetic mean among bacterial counts obtained. The observation period extended from the initial bacteriological sampling to the time when the milk became unfit for use as a sweet milk beverage. The curve representing the arithmetic distribution of the observations was so far removed from the standard normal curve that calculations based on it appeared to be of small value. Because of the long range of geometrically increasing plate counts and the relatively short range of lineally decreasing reduction times the % variations and coefficients of variability between the highest and lowest counts in any series did not show relative variability and hence accuracy between the 2 methods. When used as an index of the keeping quality of milk, the observations suggested that the logarithmic values of plate counts were less variable in milk of low bacterial content, while the reduction times were less variable in milk of high bacterial content. One method appeared to be practically as accurate as the other over the entire range of keeping quality, and both were more accurate than the actual bacterial plate counts.—*H. W. Marston (courtesy Exp. Sta. Rec.).*

7724. **ROBERTSON, A. H., RUTH I. MOODY, and J. M. FRAYER. Variability, accuracy, and adaptability of some common methods of determining the keeping quality of milk. II. Observations in sextuplicate.** *Vermont Agric. Exp. Sta. Bull.* 315. 1-39. 24 fig. 1930.—Each of 152 samples was divided into 6 parts; from these were prepared in duplicate agar plates, reductase tests and milk smears. From the 6th sample 5 similar series were also prepared in duplicate. The reductase test was more variable than the other tests, especially with milk containing but few bacteria. The degree of relationship between the reductase test and agar plate counts was greater than between the reductase test and microscopic counts. The microscopic method used was less accurate than the agar plate method.—*H. W. Marston (courtesy Exp. Sta. Rec.).*

7725. **ROBERTSON, A. H., and J. M. FRAYER. Variability, accuracy, and adaptability of some common methods of determining the keeping quality of milk. III. Observations at different temperatures and at successive intervals on the same sample.** *Vermont Agric. Exp. Sta. Bull.* 316. 1-55. 18 fig. 1930.—Samples of milk were held at 50, 60, 70, and 80° F. until sour or otherwise unfit for beverage purposes. When the samples were received at the laboratory, and usually at successive 2-hr. periods after arrival, each sample was plated in triplicate, 2 microscopic preparations were made, 2 reductase tests were prepared, and the titratable acidity was determined. Determining titratable acidity was unsatisfactory for estimating keeping quality, especially when the milk was of excellent or medium quality. Normal milk must usually contain more than 1,000,000 bacteria per cc. before any appreciable increase in titratable acidity can be detected. Tests depending on bacterial numbers were characterized by a lag phase in fresh milk containing few bacteria. During the lag and positive accelerative growth phases, more rapid changes took place in the milk, as revealed by keeping quality, than was evidenced by the corresponding increase in numbers of bacteria. This condition was regarded as indicating a lack of sensitivity. The reductase test often showed milk to be of much poorer quality than was really the case, a condition regarded as too sensitive. The relatively few fields examined indicated that these counts showed a greater lack of sensitivity among milk samples containing less than 100,000 bacteria per cc. than did the plate counts. The periods of sensitivity and lack of sensitivity were more extended as lower temp. were used for holding the samples, the relationship between all tests being more consistent when the samples were held at 70-80°. The data indicated that the mean time required for a 100% increase in bacterial numbers at each respective temp. was 1½ hrs. at 80°, 2 hrs. 25 min. at 70°, 4 hrs. 10 min. at 60°, 8 hrs. 13 min. at 50°, and 39 hrs. 14 min. at 40°. There was a high degree of similarity and a small amount of variability in the bacterial growth relations when calculated from the values obtained by each of these methods. The combined results indicate that the reductase and microscopic tests can be used satisfactorily when rapid results are desired, and that the agar plate count offers the most accurate and practical method of determining the bacterial content of milk containing relatively few bacteria.—*H. W. Marston (courtesy Exp. Sta. Rec.).*

7726. **ROBERTSON, A. H., and J. M. FRAYER. Variability, accuracy, and adaptability of some common methods of determining the keeping quality of milk. IV. Correlation studies.** *Vermont Agric. Exp. Sta. Bull.* 317. 1-154. 70 fig. 1930.—The data indicated that the logarithms of the individual microscopic counts showed a closer relationship to keeping quality of milk than the reductase test or the logarithms of either the clump or the agar plate counts. The reduction times were more closely related to the logarithms of the agar plate counts than to those of the microscopic counts. Agar plate counts when interpreted in terms of their logarithms, because they lend themselves more satisfactorily to straight line relationship throughout the entire range and because the method is adaptable to milk containing few bacteria, offer a more accurate and practical method for estimating the keeping quality of milk than either the reductase test or the microscopic method. While use of logarithms lacked strict accuracy in all of its ramifications as applied to milk in which the lag or accelerative growth phase persisted, their use so well fitted the data that their practical application could not be ignored, especially when the observations were made at 70° and 80°. For determining the method to be used, the authors suggest that where it is necessary to know only whether the milk is good, medium or poor, the reductase test will furnish the information; but for determining the cause of poor milk the microscopic method is best suited. When premiums are paid for quality milk the agar plate counts furnish most reliable information.—*H. W. Marston (courtesy Exp. Sta. Rec.).*

7727. **ROBERTSON, A. H., and J. M. FRAYER. Variability, accuracy, and adaptability of some common methods of determining the keeping quality of milk. V. The broader aspects of variability.** *Vermont Agric. Exp. Sta. Bull.* 318. 1-54. 58 fig. 1930.—A summary of the results reported in the preceding 4 papers relative to variability.—*H. W. Marston (courtesy Exp. Sta. Rec.).*

7728. **WOLF, C. H. Die Erkennung dauerpasteuri-**

sierter Milch. *Deutsche Tierärztl. Wochenschr.* 38(28): 443-446. 1930.—Tests by Hock's method for individual samples of raw milk and milk heated by the holding process, yielded amounts of serum deviating completely from the limiting values obtained by Hock. A single sample sometimes yielded marked variations, for which no explanation is forthcoming. Hock's method of detection of milk pasteurized by the holding process unfortunately does not seem adapted for a control measure.—*Author's summary (transl. by G. L. A. Ruehle).*

7729. **BURK, DEAN, and HANS LINEWEAVER. The influence of fixed nitrogen on Azotobacter.** *Jour. Bact.* 19(6): 389-414. 11 fig. 1930.—The equilibrium concentration of rapidly available fixed N in the culture medium required to inhibit N fixation by *Azotobacter* is 0.5 mg. per 100 cc. The rate of growth as a function of concentration of rapidly available fixed N passes through a maximum at 0.5-1.0 mg. per 100 cc., falling off sharply at lower, but much less rapidly at higher, concentrations. The efficiency of growth in fixed N increases with rate of growth. Hence, although increases in rates of respiration may be used as a qualitative measure of amounts of growth occurring simultaneously, the ratio, growth: respiration rate increase, increases rapidly with rate of growth, which in turn may depend on pressure of N gas, concentration of fixed N, presence of humic acid, O concentration, age of inoculum, and time. The % composition of N in the dry matter of the cells varies little, whether the N supply is chiefly free or fixed. Fixation seems to be a function resorted to only in absence of sufficiently available fixed N. The various physiological functions of respiration, growth, efficiency, etc., of *Azotobacter* in free and fixed N is quite similar; hence no conclusion can be drawn concerning the chemical mechanism of N fixation.—*H. Lineweaver.*

7730. **CASTELLI, T. Développement symbiotique d'azoto bactéries et de clostrides azoto fixateurs sur les plaques de terre modelée. [Symbiotic development of Azotobacter and Clostridium on plaques of modeled earth.]** *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(7/8): 359-360. 1931.—Following Winogradsky's method, colonies of aerobic and anaerobic N-fixing bacteria developed at the surface. One prevails over the other according to the physical and mechanical conditions of the soil.

7731. **CHIRIȚESCU-ARVA, M. Rapport entre certaines propriétés physiques de quelques sols de types morphologiques différents et le nombre des bactéries contenus dans ces sols.** *Ann. Sci. Acad. Hautes Études Agron. Bucarest* 2: (3-11). 1930.—Studies on samples of Rumanian soils indicated that maximum hygroscopicity, high organic matter content and pH of 7.2-8.0 favor the greatest development of bacteria. Soils of the chernosem type, because of their superiority in hygroscopicity and organic matter and their favorable reaction, were found to contain greater numbers of bacteria than those of the podsols and dry land (soil of the steppes) types.—*M. Chiriţescu-Arva (transl. by L. T. Leonard).*

7732. **FIFE, J. M. Respiration studies on Azotobacter under controlled conditions.** *Science* 73(1898): 533-534. 1 fig. 1931.—Experiments with 1200 cc. of a 24-hr. culture proved that the rate of respiration remained constant at 78% O for 4½ hrs. O concentration was 60-90% for 6½ hrs. as shown by 8 CO_2 determinations. The O: N ratio (78% O) giving maximum rate of respiration is the same as that in the nitrate ion.

7733. **GUTSCHY, LJUDEVIT. Rezultati pokusa dubrenja leguminoza bakterijskim preparatima. [Experimental results of inoculating legumes with nodule bacteria.]** [With German summary.] *Gospod.-Šumarski Fakult. Sveučil. Kraljev. Jugoslavije u Zagrebu, Spomenica Fakult. Savjeta (Fac. Agron. et Forest. Univ. Roy. Yougoslave Zagreb, Mem. Cons. Fac.)* 1919-1929: 537-555. 2 fig. 1929.—Increased yields were obtained: for red clover 30%; for field vetch 34.6%. To learn the action of inoculation, studies were made of: (1) number of nodules on the roots; (2) formation of the root system, and (3) comparative rapidity of development of the inoculated and uninoculated plants; also whether all sorts of soils constantly harbor a sufficient number of organisms which could be brought into activity by a proper soil treatment, or whether certain types of soils are lacking in these bacteria. Certain types of soils (peats, compact loams, virgin soils, etc.) were found which contained very few nodule bacteria; in such soils even the most favorable mineral fertilization could scarcely bring the nodule bacteria to a sufficient development. Given proper conditions, in most cases results of inoculation are favorable. The most important conditions for successful use of inoculation are: presence of K and phosphates in the soil, a neutral reaction (by addition of lime), a proper moisture content, and good permeability for air and water.—*From author's summary (transl. by I. V. Shunk).*

7734. **JARACH, M. Streptothrix rubescens, n. sp.** *Soc. Internaz. Microbiol. Boll. Sez. Italiana* 3(2): 43-45. 1931. —*Strep.* rubescens (p. 43) was isolated from soil.

7735. **PEROTTI, R., e F. MASTALLI. Studi microbiologici sui terreni della Maremma di val di Cecina. [Microbiology of the swampy soils near Cecina, Italy.]** *Boll. R. Ist. Sup. Agrar. Pisa* 3: 341-383. 4 pl., 1 map. 1927.

7736. **PHILLIPS, MAX, HERMAN D. WEIHE, and N. R. SMITH. The decomposition of lignified materials by soil microörganisms.** *Soil. Sci.* 30(5): 383-390. 1930. —The decomposition of 4 typical lignified plant materials—corn stalks, oat hulls, corn cobs and wheat straw—through the action of soil microorganisms was studied in 3 experiments, using a Czapek solution or a modified medium, treated with 10-25 gm. of oven-dried materials and inoculated with a soil infusion. After incubation, loss in wt. was determined and analyses were made for pentosans, cellulose, lignins, ash, methoxyl and N, using the best methods available for each determination. A rapid decomposition of pentosans and cellulose occurred. Lignins were decomposed by soil organisms, and under suitable conditions the rate of decomposition was about as rapid as that of cellulose.—*P. E. Brown.*

7737. **SANDON, H. A note on the microbiology of Wicken Fen soils with special reference to the protozoa.** *Nat. Hist. Wicken Fen Pt.* 4. 366-370. 1928.

7738. **WILLIAMS, P. H. Further studies of the microflora of certain tomato soils.** *Exp. & Res. Sta. Nursery & Market Gard. Indust. Devel. Soc. Turner's Hill, Cheshunt, Herts, Ann. Rep.* 16: 30-40. 1930(1931).—The numbers of bacteria in certain soils were determined at weekly intervals throughout the season. Changes in numbers could not be correlated with changes in soil temp. or humidity. Stable manure and hoof and horn increased the numbers markedly. The presence of organic N may possibly be the cause of the rapid fluctuations in numbers throughout the season.

GENERAL BACTERIOLOGY

R. E. BUCHANAN, *Editor*

(See also in this issue Entries 6356, 6360, 6382, 6387, 6532, 6537, 6562, 6563, 6576, 6578, 6579, 6643, 7395, 7400, 7469, 7576, 7590, 7591, 7613, 7618, 7619, 7620, 7631, 7680, 7686, 7707, 7729, 7732, 8046, 8059, 8079, 8263)

7739. ANTHONY, E. E., Jr. A note on capsule staining. *Science* 73(1890): 319-320. 1931.—Best results were obtained by use of 1% aqueous solution of crystal violet, 84% dye content.

7740. BROTZU, G. A propos des rapports entre le bacille de Bang et le Micrococcus melitensis. *Soc. Internaz. Microbiol. Boll. Sez. Italiana* 2(6): 338-344. 1930.—Strains of *Brucella* from 3 sources were studied: bovine strains from districts where undulant fever did not exist; strains from goats in regions where undulant fever was endemic; and porcine strains. No test was found which would distinguish the groups with certainty; with every test a few strains of each group would be found to have characteristics belonging in general to another group. The writer considers that bovine strains are pathogenic for man only if resistance is lowered, if the inoculating dose is heavy, or if the strain is relatively virulent, as, e.g., if it has been recently transferred from goats to cattle.—*Alice C. Evans.*

7741. BUC, E. Procédé de culture du Bacille de Koch dans les épanchements pleuraux. *Compt. Rend. Soc. Biol.* 98(17): 1495-1497. 2 fig. 1928.—Glycerinated peptone to which had been added monobasic potassium phosphate gave excellent results.

7742. CORBET, ALEXANDER STEVEN. An organism found in the latex of Hevea brasiliensis. *Jour. Bacteriol.* 19(5): 321-326. 1930.—*Bacillus* pandora (p. 325) is found in abundance in coagulating *Hevea* latex samples from various parts of the Malay Peninsula; it differs from "Bacillus No. 1" of Dernier and Vernet only in being Gram-positive and in ability to digest albumin; the 2 may be identical. The organism is almost certainly responsible for the important change occurring during the natural coagulation of *Hevea* latex.

7743. CUNNINGHAM, A. The life-cycle of Bac. saccharobutyricus von Klecki. *Bact. Sect., Fifth Internat. Bot. Congr., Cambridge, Sect. B* p. 13-14. 1930.—An abstract. (See also following abstract.)

7744. CUNNINGHAM, ANDREW. The life-cycle of B. saccharobutyricus von Klecki. 2. The large rod, coccoid and short rod phases. *Zentralbl. Bakt. II. Abt.* 82(23/26): 481-494. 1 pl., 6 fig. 1931.—Pure cultures were submitted to systematic morphological and cultural studies, in which the methods described in pt. 1 were employed. A number of types of cocci and rods, differing morphologically and culturally from the parent strains, were obtained and classified as large rods, cocci, and short and slender rods. The morphological, cultural and biochemical characteristics of the large rods, cocci and short rods are described in detail, and the characterisation of the various types is discussed. The large rods include types similar to *B. ellenbachensis* Caron and *B. sphaericus* A. M. et Neide; the cocci consist of forms identical with *Micrococcus candicans* Flügge, *M. aurantiacus* Cohn. and *M. roseus* (Bumm) Lehm. et Neum.; the short rods are represented by *B. candicans* Frankland and a red form otherwise similar to it. Controlled experiments in which the forms referred to were secured from cultures of *B. saccharobutyricus*, are described.—*A. Cunningham.*

7745. EYRE, J. W. H. Bateriological technique. A laboratory guide for medical, dental, and technical students. 3d ed. 614p. 238 fig. Baillière, Tindall & Cox: London, 1930. Price 21s.

7746. GRAY, J. D. A. New lithium selective and enrichment methods for the isolation of Salmonella organisms. *Jour. Path. and Bact.* 34(3): 335-342. 1931.—Staphylococci, *B. faecalis alkaligenes* and *Salmonella* are resistant to lithium salts, which may be used to advantage for differential isolation media.—*A. E. Boycott.*

7747. HOLLANDE, A. CH., et G. CRÉMIEUX. Histochimie du Bacille de Koch. *Compt. Rend. Soc. Biol.* 98 (17): 1529-1530. 1928.—The authors conclude from staining reactions (vital, and on fixed material) that the Much granules are not oxidases, mitochondrial granules, Golgi apparatus or a vacuome, but that they appear to be supporting substances for lipoidal reserves, weakly acid in reaction, arranged on a protein substratum comparable but not similar to metachromatin.

7748. JOHNSON, TREAT B., and ALICE G. RENFREW. Carbohydrates in biological processes. Observations on fractions of the tubercle bacillus. *Amer. Rev. Tuberc.* 22(6): 655-663. 1930.—The evidence to date indicates that sugars probably are among the most important constituents of the bacterial cell. They function in all the independent fractions which the authors have thus far been able to separate according to present technique. As separated from these fractions, they are very impure, being contaminated with inorganic salts and nitrogenous material of protein nature.

7749. KAUFFMANN, FRITZ. Der Typus "Berlin" der Paratyphus C-Gruppe. *Zeitschr. Hyg. u. Infektionskr.* 110(3): 537-555. 1929.—A new cultural type of paratyphoid C ("Berlin") occurs as the cause of food poisoning in man. The paratyphoid C group may be divided into 5 cultural types, viz., America, Kunzendorf, Glässer-Voldagsen, Orient, and Berlin. The Berlin type ferments arabinose, dulcitol, mannite, maltose and inositol; it is the only C type attacking inositol. In Bitter's rhamnose whey and in Stern's glycerin-fuchsin bouillon, it causes, after 20 hrs., an intense reddening. Serologically the paratyphoid C group falls into 2 divisions, a diphasic (specific and non-specific) and a monophasic (non-specific) phase, already described by Andrewes, Savage and White. The non-specific phase of both di- and monophasic strains can be further subdivided into "relatively specific" and "non-specific" phases. The Berlin type belongs to the monophasic non-specific paratyphoid C group. In a recently diagnosed "Berlin" case, where the "Berlin" bacillus was obtained from urine and stool 3 times, the Widal was positive 1:320 for "Berlin" and other non-specific C strains, and negative for typhoid, Gärtner, Schottmüller, Breslau and Newport strains.—*Maud L. Menten.*

7750. KAUFFMANN, FRITZ. Zur Frage der Typ-Umwandlung von Paratyphus C in Gärtner-Bacillen. *Zeitschr. Hyg. u. Infektionskr.* 110(3): 556-566. 1929.—A strain composed of paratyphoid C (type Berlin) and Gärtner components was, after separation, grown as pure C and Gärtner strains. 7 Russian and Turkish strains belonged culturally and serologically to the Gärtner group. By means of arabinose, Bitter's rhamnose whey, and Stern's glycerin-fuchsin bouillon, the Gärtner strain can be divided into 2 types. The significance of the stem form, and the normal serologic variations within a type for the criterion of type limitation or type transformation, is discussed. The latter is left an open question.—*Maud L. Menten.*

7751. KEMP, H. A. Gram reaction in crushed yeasts. *Stain Technol.* 6(2): 53-56. 3 fig. 1931.—Thick smears of yeasts are dried, crushed between slides or coverslips, stained with anilin crystal violet for 1½ min., Lugol's iodine solution 2 min., decolorized in undiluted anilin oil, and counterstained with 1% aqueous safranin. Photomicrographs are given of crushed yeasts thus stained, which show a Gram-positive outer layer and a Gram-negative inner substance.—*Author (courtesy Wistar Bibl. Serv.).*

7752. KURAUCHI, K. Differentiation of B. pestis from allied organisms by means of their biological properties. On a plague bacillus-like strain isolated from a suslik. Plague studies III. *Kitasato Arch. Exp. Med.* 8(1): 45-59. 1931.—It is concluded from catalase content

and behavior on various media, that the strain isolated from suslik (*Citellus*) was *Bacillus pestis*.

7753. **LAGRANGE, E.** Sur quelques particularités des Vibrions cholériques. *Compt. Rend. Soc. Biol.* 98(17): 1526-1527. 1928.—4 cultures of cholera vibrio varied widely in their agglutination reactions; some were proteolytic, some coagulated proteins.

7754. **LESLIE, P. H., and A. G. SHERA.** A new serological type of Salmonella. *Jour. Path. and Bact.* 34 (4): 533-537. 1931.—A new type of Salmonella (Eastbourne type), is described; it was isolated from the blood of a patient with a typical attack of paratyphoid fever. This organism has been submitted to a detailed antigenic analysis, using the agglutinin absorption method. It is diphasic as regards flagellar agglutinins. In its specific phase it is closely related to the Newport and Reading strains; but its group phase is allied more closely to the Reading-suipestifer than to the aertrycke-Newport group. The somatic antigens are similar to those of *S. enteritidis* Gaertner.—*P. H. Leslie.*

7755. **LOGHEM, J. J. van.** Terminology of bacterial variability. *K. Akad. Wetensch. Amsterdam, Proc.* 34 (2): 309-311. 1931.—The following terms are proposed in behalf of the physiological conception (individuality theory) of bacterial variability given before by the author: Adaptates, Mutilate, Atropheont, and Degenerant.

7756. **MAGOON, C. A., and B. C. BRUNSTETTER.** A new vessel for the efficient aeration of bacterial cultures in liquid media. *Jour. Bacteriol.* 19(6): 415-422. 1930.

7757. **MERRILL, MALCOLM H.** Utilization of carbon compounds by mycobacteria in a synthetic medium. *Proc. Soc. Exp. Biol. & Med.* 28(5): 472-474. 1931.—Preliminary paper.

7759. **NAKATA, KAUGORO.** Accessory food substance in relation to growth of Bact. hyacinthi. [In Japanese, with English summary.] *Ann. Phytopath. Soc. Japan* 2(4): 339-349. 7 fig. 1931.—An accessory food substance was proved essential for growth of *Bact. hyacinthi* Smith. It is contained more in the bodies or staled solution of *Bact. solanacearum* and less in oryzanin, both being available to the organism. This substance was denatured by filtering through filter paper and destroyed by heating at 100° C. for 30 min. on 3 successive days. It is more soluble in water than in alcohol. The author is inclined to believe that it may be identical with vitamin D. The amount of this substance necessary for growth is fixed (3% in beef bouillon when oryzanin is used as source). An excessive amount had no noticeable influence on growth, but a low amount limited growth proportionally to the amount present. With excessive supply, final growth was always the same, though slightly increased at the beginning; this may be due to the population density of the organism.—*Author's summary.*

7760. **O'MEARA, R. A. Q.** A simple, delicate and rapid method of detecting the formation of acetylmethylcarbinol by bacteria fermenting carbohydrate. *Jour. Path. and Bact.* 34(4): 401-406. 1931.—A method is described whereby formation of even very small amounts of acetoin may be detected as a routine procedure, by addition of creatine. *Escherichia communior* (Durham) may be shown to produce acetoin; and it is suggested that it should be placed in *Aerobacter*. Acetoin formation may also be shown with such organisms as *Vibrio finkler-prior, Corynebacterium diphtheriae* and *Staphylococcus aureus.*—*R. A. Q. O'Meara.*

7761. **PETRAGNANI, G.** Premières recherches sur la culture des bacilles de Koch sur milieu préparé moyennant la "cire jaune." [Preliminary researches on culture of tubercle bacilli in medium prepared by means of "yellow wax."] *Soc. Internaz. Microbiol. Boll. Sez. Italiana* 3(6): 302-303. 1931.

7762. **QUIROGA, RUPERTO.** Acción de la tripaflavina sobre los bacilos diftéricos. *Quinta Reunión Soc. Argentina Patol. Reg. Norte* 1: 391-403. 1930.—A 1/1,000,000 trypaflavin concentration in diphtheria bacillus cultures causes loss of virulence and of hemolyzing properties, as well as enabling them to grow thenceforth on oleate-agar.—*Author's conclusions* (*transl. by A. de Assis*).

7763. **REGENDANZ, P., et K. KIKUTH.** Sur la Bartonella muris ratti (Mayer). *Compt. Rend. Soc. Biol.* 98(17): 1578-1579. 1928.—Inability to infect splenectomized rats with *B. bacilliformis*, but with subsequent infection by *B. m. ratti*, is considered cause for maintenance of the specificity of the 2 forms.

7764. **SHOETENSACK, MARK.** A simple and practical method for the isolation of anaerobic microbes. *Kitasato Arch. Exp. Med.* 7(3): 310-313. 2 fig. 1930.—The author found that Na_2CO_3 crystals and pyrogallic acid placed above the cotton plug of the test tube and pushed down sufficiently to allow the tube to be corked, gave a strong enough absorption of O for anaerobiosis.

7765. **THOMAS, STANLEY.** Laboratory manual in bacteriology. ix+154p. McGraw-Hill Book Co., Inc.: New York; McGraw-Hill Publ. Co., Ltd.: London, 1930. Price 8s. 9d.

7766. **WILSON, P. W., W. H. PETERSON, and E. B. FRED.** The relationship between the nitrogen and carbon metabolism of Clostridium acetobutylicum. *Jour. Bact.* 19(4): 231-260. 1930.—*Cl. acetobutylicum* is able to use protein (wheat gluten and casein), peptone, and amino-acid mixtures (aminoids) as sources of N, with only slight changes in the ratio of solvents produced. There is evidence that it uses part of the amino-acids as such, without deaminization. In presence of aminoids, a large increase in synthesized protein takes place. While the organism cannot use ammonia N alone, it appears to utilize NH_4 salts preferentially in presence of protein nitrogen; the maximum utilization with complete fermentation was obtained with ammonium carbonate. NH_4 salts of mineral acids were utilized to a far less extent. Ammonia N is used less readily in presence of simple forms of organic N, such as peptone and amino-acids, than in presence of native proteins such as are found in corn. The ratio of solvents is changed if ammonium N is supplied, its effect being due to the acid liberated, which lowers the pH; there also appears to be a specific action of the acid. Nitrate N, as the K or NH_4 salt, is not used by the organism alone or in presence of undegraded protein N.—*M. W. Jennison.*

7767. **ZIKES.** Die Geisselfärbung. *Zentralbl. Bakt. II. Abt.* 81(8/14): 161-166. 1930.—A novel technique is presented for preparation and fixation of smears using the condensed vapor of a bacterial suspension, and for careful drying of the smears. Staining methods of Löffler, Bunge, L. Valentis, Gemellis, Petragni, Plimer & Peine, K. Imai & H. Hidaka, Peppler, van Ermengem, Hinterberger, and Zettnow are presented in detail. To these are added modifications and suggestions by the author.—*G. F. Gillen.*

7768. **ANONYMOUS.** Laboratory manual in general microbiology, prepared by the Laboratory of Bacteriology and Hygiene, Michigan State College. 3rd ed. xxvi+472p. 72 fig. John Wiley & Sons: New York, 1926.

7769. **ALLISON, J. R. The use of spray oils on citrus fruit trees.** *California Citrograph* 16: 415, 437. 1931.—In recent years oil sprays have been of great value for the control of citrus pests, but certain scales have required a follow-up fumigation and even that does not always give satisfactory control. A description is given of the most satisfactory method of preparing oil sprays at the spray tank.—*C. S. Pomeroy.*

7770. **DANIEL, DERRILL M. The oriental peach moth [Laspeyresia molesta].** *New York State Hort. Soc. Proc. Ann. Meet.* 76: 8-10. 1931.—The peach moth is present in 19 counties of the state. 75% and 80% reduction in fruit infestation were secured, respectively, by ten applications of a sulphur-oil dust and six applications of a summer oil spray. The cost of treatment exceeded the profits therefrom. Nineteen colonies of *Macrocentrus ancylivora* were established in Niagara county. Eight per cent of twig-infesting larvae were parasitized in these colonies. In 7 colonies established in 1928-29, 50% of the twig-infesting larvae were parasitized.—*D. M. Daniel.*

7771. **[GERASIMOV, A. M.] ГЕРАСИМОВ, А. М. Огневка-плодожорка, Euzophera bigelia Zell. (Lepidoptera, Phycitini), новый вредитель яблок в Средней Азии. [E. bigelia, a new pest on the apple in Central Asia.]** Русское Энтомологическое Обозрение. (*Rev. Russe d'Ent.*) 24(3/4): 179-181. 3 fig. 1930.—In 1928 an infestation of *E. bigelia** was found in apples near Old Bukhara running as high at 70-80%.

7772. **GRANDI, GUIDO. Le Hoplocampa dei Susini nell'Emilia. Nota preliminare. [The plum Hoplocampa in Emilia.]** *Ann. Tecnica Agraria* 1: 59-62. 1928.—Preliminary note on the biology of *H. minuta* Christ., *flava* L., and *testudinea* Kl., which live in the fruits of plum trees in Emilia, Italy. Life histories and habits are discussed and control measures are suggested.

7773. **GRANOVSKY, A. A. A new pest of the cherry.** *Amer. Fruit Grower Mag.* 1930(Feb.): 21. 1930.—In Wisconsin the case-bearer (*Coleophora pruniella*), which formerly fed on the leaves of the wild cherry, is becoming a serious pest in certain cultivated cherry orchards. The life cycle of this insect is described. It may be controlled, with difficulty, by oil emulsion sprays.—*W. S. Clarke, Jr.*

7774. **HODGKISS, H. E. The relation of insect control to the arsenic content of spray residues.** *Pennsylvania Hort. Assoc. News* 8(1): 18-27. 1931.—The effectiveness of a definite program of apple orchard insect control is illustrated by comparisons in 10 orchards over a 3-yr. period. Insects concerned in state wide operations are the rosy apple aphis, apple red bugs, leaf rollers, which are taken as a group, plum curculio, and codling moth. Suppression of these spp. during 1930 is discussed separately with supporting charts. State wide figures indicate comparative loss valuations under the Pennsylvania system of apple spraying service and the usual schedule spraying practice. Codling moth infestation was unusually large on account of extreme drought conditions in the more extensive commercial apple producing area. Under the system described, suppression was highly satisfactory. Analyses of residues from apple samples showed that the amounts of AS_2O_3 did not exceed the domestic tolerance in most instances. In the extreme drought area few samples exceeded the world tolerance for 1930. Cleaning of apples reduced the amount of AS_2O_3 per pound of apples somewhat. Residues rather than arsenic content are concluded to be the most important factors in conditioning apple fruits.—*H. E. Hodgkiss.*

7775. **HULL, FRANK M. Some possible means of control of the damage caused by the cotton leaf worm moth to the fig.** *Jour. Econ. Ent.* 22(5): 792-796. 1929.—Severe damage to fruits of the fig is caused by periodic settling of swarms of the cotton leaf worm moth (*Alabama argillacea*) and there follows a premature souring of the fruit caused by the feeding of the moths. A number of poison baits carrying sodium arsenite were tested and several gave promise of considerable success. Repellents were not found to be as effective. Experiments showed the time of greatest feeding of the moths to be just before dark and that the feeding is intermittent and lasts only a few minutes.—*W. P. Duruz.*

7776. **McGREGOR, E. A. Improvement in sulphur dusting for control of citrus thrips.** *California Citrograph* 16: 358, 386. Illus. 1931.—Citrus growers believe that a full dusting program is giving better protection than any previously known method. In addition it is significant that the majority of groves in central California that have been thoroughly dusted from 1 to 3 years are commercially free from citricola scale.—*C. S. Pomeroy.*

7777. **MASSEE, A. M. Note on plum leaf-hoppers.** *Ent. Month. Mag.* 65(784): 206-207. 1929.—The Jassids *Typhlocyba querqus* Fab. & *Zygina coryli* Collin emerged in May from the trunks and main branches of plum trees, principally *Prunus cerasifera* Ehr. They caused considerable damage to the host during the summer, and deposited eggs in the trunks and branches during Oct. A 7½% tar-distillate spray used in Jan. apparently had no effect on the eggs.—*H. M. Gilkey.*

7778. **ORCHARD, O. B. Red spider investigations on commercial nurseries.** *Exp. & Res. Sta. Nursery & Market Gard. Indust. Devel. Soc., Turner's Hill, Cheshunt, Hertz, Ann. Rept.* 15: 60-62. 1929(1930).—Extensive investigations in the laboratory and on commercial nurseries have, in all instances, failed to substantiate the theory that Red Spider Mite infestations result from the introduction of the mite in material such as straw, turf, and manure. In no instance has it

been found that the mite can survive until the spring in the soil of glasshouses.—*Author's conclusions.*

7779. [PUZANOVA-MALYSHEVA, E. V.] ПУЗАНОВА-МАЛЫШЕВА, Е. В. К биологии Eurytoma amygdali End., вредителя слив. [Biology of E. amygdali, a pest of plums.] [English summary.] Русское Энтомологическое Обозрение. (*Rev. Russe d'Ent.*) 24 (3/4): 166-178. 13 fig. 1930.—The author mentions other *Eurytoma* spp. known as plant pests, and reviews the literature on *E. amygdali*. [Chalcidoidea, Eurytomidae]. Adult ♂ and ♀ are fully redescribed, and all the stages of the life history are discussed and illustrated. Control measures are suggested. Three hymenopterous parasites were discovered: *Mesochorus nigripes*, *Ascogaster* sp., and *Sphalomaspis* sp.

7780. STANILAND, L. N., and C. L. WALTON. Progress report. Experiments on the control of pear midge (Contarinia pyrivora). *Ann. Rept. Agric. & Hort. Res. Sta. Univ. Bristol* 1929: 124-129. [1930].—The first test was to see if enough of the insects could be trapped in banding grease to reduce the damage to the fruits. Various aromatic substances were stirred into the grease. Nitrobenzene, oil of cloves, and oil of fennel seemed to attract the insects, but not in large enough numbers to reduce perceptibly the amount of damage in the orchard. Amyl acetate (commonly known as pear essence) did not seem to attract them at all. Calcium cyanide worked into the soil under the trees to a depth of 4 inches, at the rate of a half ounce or more to the square yard, was rather effective in reducing the amount of injury. Removing the soil under the trees to the same depth was effective. Tar oil washes applied to the soil under the trees were not effective. Nicotine and soft soap sprayed on the open blossoms caused a marked reduction in the amount of injury.—*W. H. Chandler.*

7781. VECHT, J. van der, en A. D. VOÛTE. Biologie en bestrijding der djeroekmot (Citripestis sagittiferella Moore). [Life-history of C. sagittiferella.] [With English summary.] *Landbouw* [*Buitenzorg*] 6(9): 881-886. 1931.—This pest, one of the severest for citrus culture in many parts of the Netherlands East Indies, in some cases destroys more than 50% of the fruits. Only *Citrus maxima*, *C. medica*, *C. aurantium* and their hybrids are infested. The eggs are deposited on the surface of the half-grown and ripening fruits and hatch 5 days later. The caterpillars burrow directly into the pulp, and when mature, some 14 days later, leave the fruit to pupate in the soil. Through the larval holes many secondary insects enter the fruits. The caterpillar constructs a cocoon of earth-particles about 1 cm. under the surface of the soil. After 10 days the moth appears. Total life-cycle requires about 1 month. Parasites are of no importance in Java. In a native garden, all infested citrus fruits were destroyed at 10-day intervals during several months but no decrease in infestation resulted, due apparently to continuous infestation from nearby gardens. Probably the moths cover long distances during their nocturnal flight. Fruits can be protected by paraffined paper bags when 6 cm. in diam.

7782. WORTHLEY, H. N. The control of the codling moth [Carpocapsa pomonella] with tree bands. (*Proc. State Hort. Assoc. 1931.*) *Pennsylvania State Hort. Assoc. News* 8(1): 13-17. 1931.—Single-faced corrugated strawboard bands 2 in. wide dipped in a mixture of 1 lb. β-naphthol and 1.5 pints red engine oil and placed about the trunks of well-scraped apple trees early in July prevented 98.8% of the expected emergence of moths of the summer brood and killed 92.2% of the 1st and 2nd brood larvae trapped, as compared with untreated bands. Double dipping and the addition of 0.5 oz. aluminum stearate increased the effectiveness of the bands. Examination of 5 well-scraped apple trees and the ground beneath in November showed 1.5% of the hibernating larvae to be on the ground, 1.66% on the tree trunk and branches, and 96.84% under the bands.—*H. N. Worthley.*

ECONOMIC ENTOMOLOGY

CEREAL, FORAGE, AND OTHER FIELD CROPS

(See also in this issue Entries 7775, 8767)

7783. AYYAR, P. N. KRISHNA. A new pest of rice in South India. *Bull. Ent. Res.* [*London*] 20(2): 173-178. 1 fig. 1929.—A change in the scheme of paddy cultivation in the area infested, which has insured an abundant and continuous supply of food for the insect throughout the yr., has encouraged the development of *Tetroda histeroides* Fabr.,—a comparatively unimportant insect until it occurred in outbreak numbers and caused much damage. Its life history is given, with descriptions of its various nymphal stages. Two parasites were reared—one possibly *Anastatus colemani* and the other possibly a Braconid. Various ineffective control measures are discussed and the one effective method of sweeping up the bugs by hand is described.—*W. H. Larrimer.*

7784. CHIAROMONTE, A. Considerazioni entomologiche sulla coltura del Cotone nella Somalia Italiana. *Bull. Agric. Congo Belge* 21(3): 739-743. 1930.

7785. COSTA LIMA, A. da. Uma nova praga do Algodoeiro no nordeste do Brasil. [A cotton pest new to northeastern Brazil.] *O campo* [*Rio de Janeiro*] 1 (9): 12-13. 7 fig. 1930.—Notes on the coccid, *Ferrisia virgata* (Cockerell) Fullaway, and on its predator, *Hyperaspis* (?) *noticollis* (Muls.).

7786. DINGLER, MAX. Die Griesheimer Heuschreckenplage. [Schluss.] *Anzeiger Schädlingsk.* 7(2): 19-20. 1 fig. 1931.—The abnormal increase of the grasshopper in 1930 was due to climatic conditions and failure to use the land. To prevent recurrence, thorough cultivation, tramping down, sheep raising, harrowing, or plowing under is recommended.—*G. A. Bieberdorf.*

7787. DUNNAM, E. W. Experiments on the relation between the location of cotton fields and the intensity of boll weevil infestation the succeeding season. *Jour. Econ. Ent.* 22(5): 750-756. 3 fig. 1929.—Data collected by the author during 1928 at Tallulah, Louisiana, following the floods of 1927, with attendant restriction of cotton culture, tend to show that there is no relation between the distribution of the boll weevil infestation in 1928 and the location of the cotton plantings in 1927.—*J. L. Webb.*

7788. GROSSMAN, EDGAR F. Winter survival of immature stages of the boll weevil. *Florida Ent.* 15(1): 13-14. 1931.—Records of survival of *Anthonomus grandis* stages in cotton squares and bolls in Florida, after various periods in low temp. incubator at 55° and 80 to 90% relative humidity. No larvae survived the shortest period of 69 days; no pupae survived beyond 92 days; one adult survived 131 days, but no stages beyond 138 days.

7789. GUMLEY, E. M. Frosted orange moth in Co. Antrim. *Irish Nat. Jour.* 3(11): 232. 1931.—Note on potato stem injury by *Ochria ochracea* in Ireland.

7790. KORIĆ, MIRKO. Jugoslavia: Serious sugar beet crop losses. *Internat. Bull. Plant Protect.* 5(8): 142-143. 1931.—Damage due to weevils and chrysomelids is discussed.

7791. MEER MOHR, J. C. van der. Entomologische aanteekeningen, 1. A. Over leemnestjes op tabaksbladeren. B. Over samenklontering van tabakszaad. C. Dinoderus minutus Fabr. in tabak. [A. Mudwasps on tobacco leaves. B. Clotting of tobacco seed. C. D.

minutus on tobacco.] [With English summary.] *Mededeel. Deli Proefstat. Medan-Sumatra* 71. 1-10. 3 pl. 1931. —A. Cells of *Eumenes* sp. may sometimes be found on the underside of tobacco leaves. The cells contained paralyzed caterpillars, of spp. not harmful to tobacco.—B. A peculiar clotting of tobacco seed, perhaps caused by mites, viz. *Tyrophagus putrescentiae* (Schrank 1781), is described.—C. Mild damage to fermented tobacco by the smaller bambo shot-borer, *Dinoderus minutus* Fabr. (Col. Bostrych.), is reported. The tobacco probably became infested in the curing barn, as in Deli tobacco leaves are put on bamboo laths, some of which may have been attacked by *Dinoderus*.

7792. **MENOZZI, CARLO.** Insetti dannosi alla barbabietola. (Osservazioni ed appunti preliminari.) [Insect pests of beets.] 98p. 1 map, 4 col. pl., 25 fig. Stabilimento Tipo-Litografia Narcisi & Co.: Genova, 1930.

7793. **MUNGOMERY, R. W.** The present status of control of some Queensland sugar cane pests. *Proc. Ann. Conf. Queensland Soc. Sugar Cane Techn.* 2: 230-236. 1931.—On insect pests.

7794. **PAASCH, E.** Die wirtschaftliche Bedeutung der Rübenfliegenbekämpfung. [Economic significance of beet fly control.] *Zuckerrübenbau* 13 (4): 56-63. 1931.

7795. **ROBERTS, J. ISGAER.** The tobacco capsid (Engytatus volucer, Kirk.) in Rhodesia. *Bull. Ent. Res.* [*London*] 21 (2): 169-183. 1 pl., 2 fig. 1930.—At the beginning of the 1928-29 season, work was started to study the transmission of tobacco mosaic in Rhodesia. Mosaic is very easily disseminated by contact of plants, by planters' hands and similar ways, so that it seems easy for all sucking insects to be vectors. The source of first infection is not clearly established but it is not transmitted with the seed. Several insects were found, but inasmuch as *E. volucer* was breeding on tobacco it was suspected as the vector. Experiments proved otherwise. This capsid causes a very distinct crinkling of the foliage formerly attributed to several agencies in the soil. Other spp. of *Engytatus* and *Dicyphus* cause feeding injury wherever tobacco is grown. Tobacco has been grown in Rhodesia for over 25 yrs. At present both Virginia and Turkish tobaccos are grown. The seed beds are made in fertile soils which are burned over from 12 to 14 hrs. Heat penetration sufficient to kill potent viruses is doubtful. The method of sowing the seed and the time of planting in the field are discussed, also the effect of climate. Mention is made of the characteristics of the plant with reference to insect feeding and the effect of different soils on plant growth. The descriptions of the adult capsid and of its nymphal stages are quite complete. Its life cycle is from 12 to 14 days at the beginning of the season and upwards to 22 days at the onset of cold weather. Eggs are found throughout the tobacco growing season, deposited mostly in the midribs of the leaf where the adults prefer to feed. The inflorescence is also a favored feeding place. No other host plants have been found, but *E. volucer* is both cannibalistic and carnivorous. The article presents a very complete description of copulation and anatomy of the parts engaged. *Anthocoris fasciculatus* when allowed to feed on mosaic plants, then on healthy ones, did not produce the disease on the latter. An Aleurodid, handled the same way, except no egg deposition, did not produce symptoms of the mosaic disease. *Empoasca facialis* Jac. produced no mosaic symptoms but did produce characteristic yellowing of the leaves where the insects were allowed to feed.—*M. P. Jones.*

7796. **SMITH, J. HAROLD.** Tobacco pests. *Queensland Agric. Jour.* 36 (2): 195-212. 6 pl. (1 col.) 1931.—Wireworms, cutworms (*Prodenia litura** Fabr.), nematodes, the budworm (*Heliothis obsoleta** F.) and other leaf-eating noctuids, the tobacco miner (*Phthorimoea operculella** Zell.), grasshoppers, and thrips are discussed.

7797. **STRICKLAND, E. H.** Relative susceptibility of wheat varieties to wireworm damage. *Scientific Agric.* 12 (2): 88-91. 1931.—Laboratory and field tests indicated varietal differences in susceptibility of wheat. Marquis and Reward are recommended in preference to Garnet for heavily infested fields.

7798. **WILDERMUTH, V. L.** Chalcid control in alfalfa-seed production. *U. S. Dept. Agric., Farmers' Bull.* 1642. ii-14. 12 fig. 1931.—This is a revision of and supersedes Farmers' Bulletin 636.—*Wm. A. Hooker* (*courtesy Exp. Sta. Rec.*).

7799. **WILLIAMS, FRANCIS X., (compiled by, with the assistance of R. H. VAN ZWALUWENBURG, and O. H. SWEZEY. Introduction by F. MUIR.).** Handbook of the insects and other invertebrates of Hawaiian sugar cane fields. 400p. 40 pl. (2 col.), 143 fig. Hawaiian Sugar Planters' Association: Honolulu, 1931.—Muir, in the introduction, considers the ecological conditions from the standpoint of the origin of the islands, and gives a review of the system of biological control adopted by the Sugar Planters' Association, the philosophy which guided their procedure, and the nature of the results. The influence of additional spp. on the numerical ratios is discussed. It is not always necessary to have a complete cycle of parasites, that is one for each stage, in order to obtain satisfactory control. The insects of the cane fields are taken up order by order, with brief discussions of the spp., many of which are illustrated. While most of the spp. reported have been discussed in bulletins of the station, this is the first complete assembling of the entomological fauna of the sugar cane fields. Several unidentified Thysanura (Lepismidae, Japygidae, Campodeidae) and Collembola (Entomobryidae and Smynthuridae) from the cane fields are illustrated, some being responsible for root pitting, and others occurring behind the leaf sheaths, etc. Nine spp. of Blattidae* are discussed. The egg cases of *Cutilia soror**, *Periplaneta americana**, *P. australasiae**, *Symploce hospes** and *Euthyrrhapha pacifica** are illustrated. Only 3 spp. of introduced mantids have been taken in Hawaii. The only Acrididae injurious in the fields are the introduced *Oxya chinensis** and *Atractomorpha ambigua**, the latter occurring because of weeds. Four Locustidae* are discussed, of which *Conocephalus saltator** is the principal cane pest. Its eggs* are deposited in the leaf sheath. The mole cricket, *Gryllotalpa africana**, injures the seed cane and young shoots, and is attacked in turn by *Larra luzonensis*, introduced from the Philippines. Three spp. of Gryllidae* are listed and 5 spp. of Dermaptera*. Four species of Isoptera occur in Hawaii, *Neotermes connexus**, *Kalotermes immigrans**, *Cryptotermes piceatus**, and *Coptotermes formosanus**, of which only the latter attacks sugar cane. The only Embiid is *Oligotoma insularis*, which is of no economic importance. Seven spp. of Psocidae* and 5 spp. of Odonata* are listed. The Thysanoptera on cane are *Kentronothrips hawaiiensis**, *Thrips saccharoni**, *T. panicus**, *Chirothrips mexicanus**, and *Scolothrips 6-maculatus**. In the cane fields the Pentatomidae are represented by *Oechalia kaonohi* and *O. griseus*, which are predators on caterpillars; the Cydnidae, by *Geotomus pygmaeus**, found at the roots of plants; and the predacious Reduviidae by *Zelus renardii**, *Reduviolus innotatus* and *R. capsiformis*. The eggs of the latter are parasitized by *Polynema reduvioli*. The predacious Anthocoridae are represented by *Triphleps persequens**, *T. pumilio* and *Physopleurella mundulus**; the Miridae, by the carnivorous *Fulvius peregrinator* and *Cytorhinus mundulus**, a valuable enemy of the eggs of *Perkinsiella*. The sugar cane aphids are *Aphis sacchari**, which is attacked by the coccinellid beetles *Coelophora inaequalis**, *C. pupillata**, *Olla abdominalis**, *Diomus notescens**, *Platyomus lividigaster**, and the syrphids *Simosyrphus grandicornis**, and *Allograpta obliqua**, and parasitized by *Aphelinus maidis*, and *Lysiphlebus testaceipes*; and the corn aphis, *Aphis maidis**, carrier of mosaic, which is rare on cane. The mealy bugs of cane are *Trionymus sacchari**; *T. boninsis**, which is parasitized by *Aphycus terryi** and destroyed by the fungus *Entomophthora pseudococci*; and *Pseudococcus brevipes**. Among the mealy bug enemies are the coccids *Crypto-*

*lacmus montrouzieri**, *Hyperaspis trilineata*, and the drosophilid fly, *Gitonides perspicax**. The principal delphacid enemy of cane is *Perkinsiella vastatrix**, against which several introduced parasites are of value. The introduced predatory hemerobiids, *Nesomicromus vagus** and *Micromus vinaceus**, are well established and valuable in control of aphids, as are also the introduced Chrysopidae, *Chrysopa lineata* and *C. microphya**. The Noctuidae are represented by the army worms *Cirphis unipuncta** and *Spodoptera mauritia**, in the control of which 9 spp. of parasites* have been satisfactorily introduced, as well as the fungus, *Metarrhizium anisopliae**. Of the Pyralidae, the sugar cane leaf roller, *Omiodes accepta**, is most important, and has quite a series of parasites*. The sugar cane bud moths, *Eucosmotis flavistricta** and *Opogona aurisquamosa**, attack the rind and buds. Various spp. of moths* are listed which occur in the fields, but all do not attack cane. Numerous cane field beetles are noted by families, with particular attention to the sugar cane wire worms, *Simodactylus cinnamomeus** and *Monocrepidius exsul**, whose larvae damage seed cane and destroy the eyes; *Gonocephalum seriatum** and its parasite *Epyris extraneus**; *Anomala orientalis** and its parasite *Scolia manilae**; the Chinese rose beetle, *Adoretus sinicus**, which sometimes defoliates the cane leaves; and especially *Rhabdocnemis obscura**, the New Guinea sugar cane beetle borer, and its valuable introduced parasite, *Ceromasia sphenophori**; and a fungous disease, a *Sporotrichum** from Celebes. A list of 27 cane field ants* is discussed. Many species of predatory and parasitic Hymenoptera* are discussed. Notable among the cane Diptera are *Phaenobremia meridionalis*, a predacious cecidomyid whose larva attacks the *Aphis sacchari;* and *Archytas cirphis**, an introduced tachinid enemy of the army worm. A short section deals with the enemies of nutgrass, *Cyperus rotundus*, especially the moth borer, *Bactra truculenta**, and the weevil, *Athesapeuta cyperi*. The next section deals with the millipedes*, centipedes*, scorpions*, spiders*, mites*, crustacea*, molluscs*, and planaria* of the cane fields. R. H. VAN ZWALUWENBURG discusses the soil population of cane fields, finding in the upper 9 inches, that, of all animal life except nematodes, 66.9% are insects, 25.2% myriapods, 7.7% arachnids, 0.08% crustaceans, and 0.04% worms. In another chapter he discusses the nematodes of sugar cane, especially *Tylenchus similis** and *Heterodera radicicola**, from an ecological standpoint. O. H. SWEZEY tabulates the records of successful and unsuccessful importations of beneficial insects. The bibliography is very extensive (pp. 378-389).

7800. WILLIAMSON, JUAN. El gusano de la caña del trigo. [The wheat culm grub.] *Argentina Min. Agric. Sec. Propaganda e Informes* 831. 169-172. 1931.—Damage produced by larvae of the curculionid beetle, *Prosaldius rufus* Hust., is described.

FOREST AND SHADE TREES

J. M. SWAINE, *Editor*

(See also in this issue Entries 6398, 6414, 8007, 8767)

7807. DROSIHN, P. Die Kiefernspannerbekämpfung in Thüringen 1929. *Forstwiss. Centralbl.* 52(10): 478-492. 2 fig. 1930.—A total area of 350 ha. was dusted with 11,906 kgm. "forstesturmit" during the latter part of August, completely suppressing a threatened outbreak of the pine looper, *Geometra piniaria.—W. N. Sparhawk.*

7808. EIDMANN, H. Die Bekämpfung von Frostspanner und Eichenwickler durch Arsenbestäubung mittels Motorverstäuber. *Mitteil. Forstwirtsch. u. Forstwiss.* 1(4): 355-384. 9 fig. 1930.—Experiments in control of *Cheimatobia brumata* and *Tortrix viridana* on oak are described. A patented powder, "Meritol," containing 20% As_2O_5 was applied with a motor duster at the rate of 50 kgm. per ha. It quickly checked the infestation of *C. brumata* but was less effective with the leaf-roller.—*W. N. Sparhawk.*

7809. EIDMANN, H. Die forstliche Bedeutung der Ameisen. *Mitteil. Forstwirtsch. u. Forstwiss.* 1(4): 515-525. 4 fig. 1930.—Although some ants, such as *Camponotus herculeanus*, do considerable damage by hollowing out the stems of standing trees, others (as *Lasius flavus*) help to keep the soil in good condition by loosening it and mixing it with organic matter, or help to spread the seeds of various plants. The principal benefit is destruction of insect pests, especially by the red forest ant (*Formica rufa* and related forms). During a summer, a large colony of these ants destroys about

2 million insects, of which about ½ are harmful and only ⅛ useful. The red ant thus helps greatly in preventing epidemics of forest insects.—*W. N. Sparhawk.*

7810. **[FEDOROV, S. M.]** ФЕДОРОВ, С. М. Вредные насекомые лесов Крыма. [Insect pests in the forests of Crimea.] Русское Энтомологическое Обозрение. (*Rev. Russe d'Ent.*) 24(3/4): 225-229. 1930.—Eleven spp. are listed as attacking *Pinus*, 23 on *Quercus*, 4 on *Fagus*, and 1 on *Carpinus*. There are notes on distribution and on the type and extent of the damage done.

7811. **FRIEND, ROGER B. The European pine shoot moth in red pine plantations.** *Jour. Forest.* 29(4): 551-556. 1931.—This insect (*Rhyacionia buoliana* Schiff.) was first reported on Long Island, N. Y., in 1914, and has since spread to 11 states, including Florida, Ohio, Illinois, Michigan, and the New England States, and to Nova Scotia, Ontario, and British Columbia. American hosts include *Pinus strobus, P. resinosa, P. ponderosa, P. taeda, P. palustris, P. banksiana*, and *P. contorta*, though not all have been attacked in America. The insect appears to be single-brooded in America. Data are given on damage to planted red pine in Connecticut, and on attempted control by spraying and by cutting out infested tips. Injury to red pine is serious, but infestations spread slowly and control seems feasible.—*P. C. Wakeley.*

7812. **GAILIŠ, L. Celmu mizošanas nozīme Latvijā.** [The importance of peeling stumps in forest operations in Latvia.] *Mežsaimniecības rakstu krājums* [*Riga*] 6: 85-104. [German summary, 136-141.] 1928.—The following conclusions resulted from the examination of over 1,000 pine and spruce stumps on a variety of sites: Unpeeled stumps of conifers are breeding places for bark beetles, especially on clear-cut areas or in selectively-cut pine stands. Except in mixed stands on low, moist, grassy sites, stumps over 5 cm. diam. should be peeled unless they can be pulled and utilized. This will destroy the broods of bark beetles as well as of *Hylobius abietis*. Tops and branches less than 2-3 cm. diam. may be left on the ground, but larger ones should be removed or burned, since they are breeding places for the small pine beetle (*Myelophilus minor*), one of the most widespread forest pests in Latvia.—*W. N. Sparhawk.*

7813. **MENZEL, R., and T. A. TENGWALL. Slakken op Hevea.** [Snails on Hevea.] *Arch. Rubbercult. Nederlandsch-Indie* 13: 239-243. 1929.—Snails about 1 mm. in diameter of shell, identified as *Pupisoma pulvisculum*, were found on trees badly attacked by mites. They were living in groups of 3 to 10 on the leaf scars below small lateral branches. They make wounds deep into the bark, through which the latex escapes. Figures show the anatomical changes caused by the injury.—*C. D. LaRue.*

7814. **[POLOZHENTSEV, P.]** ПОЛОЖЕНЦЕВ, П. К биологии Spondylis buprestoides L. [Biology of S. buprestoides.] [German summary.] Русское Энтомологическое Обозрение. (*Rev. Russe d'Ent.*) 23(1/2): 48-59. 7 fig. 1929.—*S. buprestoides* lives in the roots of *Pinus silvestris* and *P. banksiana*, doing damage by its borings* to the trees. Among its enemies are the birds, *Motacilla alba* and *Erythropus vespertinus*, and the robber fly *Laphria.*

7815. **SCHWERDTFEGER, F. Anwendung von Kali und Kainit zur Kiefernspannerbekämpfung.** *Forstarchiv* 6(5): 81-84. 1930.—Kali and kainit were introduced into moss over soil in glass cylinders. Caterpillars of the pine looper (*Geometra piniaria* L.), ready to pupate, were introduced on the moss. The kainit caused a high mortality of caterpillars as they passed through the moss and of pupae in the soil. The effect of kali was slight. —*N. W. Hosley.*

7816. **TRÄGÅRDH, IVAR. Methods of investigating the fauna of tree-stumps.** *Bull. Ent. Res.* [*London*] 20 (2): 245-250. 1929.—Brief descriptions of the methods used and the results obtained, illustrated by diagrams and tables. Particular study of the pine weevil in Sweden indicates the desirability of avoiding large clean fellings which offer conditions particularly favorable to the insect.

7817. **WOLFF. Witterung und Ausschlüpfen von Kiefernspannerpuppen.** *Zeitschr. Forst.- u. Jagdw.* 62(5): 307-311. 1930.—Fluctuation in atmospheric pressure constitutes the immediate cause of emergence of the pine looper moth from its pupal case, in the opinion of well-informed authorities. An abrupt fall in temp. is accompanied by a pronounced decrease in the number of new moths flying from the litter. Schwerdtfeger concluded from his studies that emergence is not dependent on temp. (soil or air) or on precipitation. The danger of formulating conclusions on the basis of quantitative and graphic determinations, the scheme employed by Schwerdtfeger in his scatological observations, is pointed out. The value of direct observations is emphasized.—*J. Roeser, Jr.*

ECONOMIC ENTOMOLOGY

INSECTS AFFECTING ANIMALS

F. C. BISHOPP, *Editor*

(See also in this issue Entries 6306, 6984, 7191, 7531, 7556, 7640, 7687, 7850, 7852, 8632, 8718, 8727, 8728, 8742, 8749, 8876)

7818. **BOURGUIGNON, G. C. Myiase cutanée à Lucilia madagascariensis du canard domestique a Coquilhatville.** *Ann. Soc. Belge Med. Tropicale* 10(1): 81-83. 1 pl. 1930. —A domestic duck was observed to move about slowly but otherwise showed no symptoms of illness. A large wound was found near the tail which was filled with larvae all of which were about the same size. About 2 days later the duck died suddenly. The abdominal cavity and intestinal tract were not invaded. Notes are given on pupation and the emergence of the flies. All the flies proved to be *L. madagascariensis.—F. C. Bishopp.*

7819. **BOYD, MARK F. The cage rearing of Anopheles quadrimaculatus.** *Amer. Jour. Trop. Med.* 10(3): 165-175. 5 fig. 1930.—Describes in detail the technique by which fertile ova of *A. quadrimaculatus* were secured from cage reared stock, accounting for 3 lineal generations between the last of July and the middle of October. —*M. F. Boyd.*

7820. **BOYD, MARK F. Studies on the bionomics of North American anophelines. VI. Some observations on imagines.** *Amer. Jour. Hyg.* 12(2): 449-466. 1 fig. 1930. —*Anopheles quadrimaculatus* is, in this region [Edenton, North Carolina], an effective, and apparently the sole, transmitter of malaria. It shows a greater preference for the blood of man than do the other common species of the region. After engorgement it manifests considerable nocturnal restlessness, but continues to utilize diurnal shelters in the vicinity of its mammalian hosts until ready to oviposit. More individuals of the 3 local spp. examined had fed on the blood of cattle than on that of any other host. Some evidence is submitted to suggest that the nocturnal presence of cattle in the vicinity of human dwellings is associated with reduced malaria incidence. This is probably accomplished by a diversion of *quadrimaculatus* from man to cattle. *A. punctipennis* does not appear to be implicated in the local transmission of malaria. While showing a tendency to linger in the vicinity of their mammalian hosts until ready for oviposition, only a small proportion of *punctipennis* appear to have engorged themselves upon man. *A. crucians* does not appear to be implicated in the local transmission of malaria: it effects the maturation of its

ova in a feral environment. The *quadrimaculatus* imagines encountered during the late fall and winter months are in a state of hibernation. On the other hand, there is no protracted cessation or suspension of the activities of *punctipennis* during the winter period.—*Author's conclusions.*

7821. CAIUS, J. F. The toxicity of the venoms of Indian scorpions. *Jour. Bombay Nat. Hist. Soc.* 33(4): 952-953. 1929.—The author, stung by *Buthcolus melanurus*, Kessler, experienced a sharp burning pain for a few seconds followed by a dull throbbing pain, locally, for a few minutes. Discomfort lasted 1½ hrs. The scorpion is described.

7822. DUNN, LAWRENCE H. Rearing the larvae of Dermatobia hominis Linn. in man. *Psyche* [*Boston*] 37(4): 327-342. 1 pl., 1 fig. 1930.—In October, 1929, the author allowed himself to be infected with 6 larvae of *D. hominis* which were just emerging from eggs attached to the abdomen of the fly, *Limnophora*. He describes the development of the larvae in eruptions under the skin. This took from 46 to 52 days and was accompanied by itching, pricking and at times excruciating pain. After the larvae emerged, they were put into damp sand and sawdust where they pupated, emerging as adult flies after 22 to 24 days.—*C. W. Dawley.*

7823. HAMLYN-HARRIS, R. Mosquitoes breeding in tree cavities in Queensland. *Bull. Ent. Res.* [*London*] 22(1): 51-52. 1931.—A survey of 1299 trees in the Brisbane area yielded 64 out of 196 cavities containing *Aëdes notoscriptus*, *A. argenteus*, and *Culex fatigans*, with the first most common. The highest percentage of cavities with mosquitoes was in *Poinciana regia*, but there were more fig trees with potential breeding cavities.

7824. HOFFMANN, CARLOS C. Los mosquitos Anopheles, transmisores del paludismo en el Valle de Mexico. *Bol. Dept. Salubridad No. 2.* 11-23. 2 pl. 1929.—Malaria in this region is caused chiefly by *Anopheles pseudopunctipennis* and *A. quadrimaculatus*. For 8 or 9 weeks during the winter there is an interruption in the activity of *pseudopunctipennis*. Only larvae and adult ♀♀ survive the cold. This sp. breeds only in clear, clean water. *A. quadrimaculatus* may breed in stagnant water. It seems to be increasing in the district, probably due to imperfect drainage in new construction operations. It may breed all the year round. Suggestions are given for combating these 2 spp.

7825. ILLINGWORTH, J. F. The use of arsenic in mosquito control. *Proc. Hawaiian Ent. Soc.* 7(3): 414. 1931.—Paris green at the rate of one part to a million of water, used in greenhouses against mosquito *Aëdes aegypti*, destroyed the wrigglers but also injured the pineapple roots. Lead arsenate at the same strength gave perfect results and no injury.

7826. JACKSON, C. H. N. Contributions to the bionomics of Glossina morsitans. *Bull. Ent. Res.* 21(4): 491-527. Map, 3 fig. 1930.—The tsetse-fly *G. morsitans* was studied in Western Kondoa, Tanganyika Territory. Several lines of evidence seemed to show that flies live and breed in large woodland areas covered with *Berlinia* and *Brachystegia*, from which they emerge, when hungry, to feed on game animals. Such feeding grounds invariably occupy situations favored by frequent passage of game. The studies of the habits of the flies were facilitated by liberating and recapturing marked individuals. The causes of game movements also were studied, reactions of different spp. being correlated with such factors as presence and absence of water, long grass, and young grass.—*C. H. N. Jackson.*

7827. [KOROSTELEV, V.] КОРОСТЕЛЕВ, В. Дальнейшее наблюдение над ларвицидным свойством парижской зелени. [Further observations of the larvicidal properties of Paris green.] [French summary.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7(4): 299-303. 1929.—The author spread Paris green powder over water reservoirs, to kill larvae of *Anopheles maculipennis*. Rapidity of death of the larvae was directly proportional to the temp. of the water and to the dose of the larvicide. Applied in necessary minimal doses, Paris green, under natural conditions, is not dangerous for animals. This was demonstrated by experiments on dogs. Dusting water surface with Paris green presents no danger to fish. Cloudy weather and rain do not prevent the larvicidal action of Paris green in natural environments. Water treated with Paris green is reinfested by mosquito larvae only after an interval of 3-4 weeks.—*B. Van Rosen.*

7828. NASH, T. A. M. A contribution to our knowledge of the bionomics of Glossina morsitans. *Bull. Ent. Res.* 21(2): 201-256. Map. 1930.—The flies, *G. morsitans*, emerge from their puparia during both the short and long dry seasons. During both rainy seasons emergence is extremely low. Fly density is greatest at the end of the heavy rains and least at the end of the long dry season, and during the light rains. The cold spell and the bush fires cause a great drop in density. Density remains steady at a medium high level throughout the heavy rains. The order of fly preference for the vegetational communities is as follows: *Brachystegia microphylla, Acacia usambarensis, Berlinia globiflora, Combretum savannah, Acacia spirocarpa, A. campylacantha* and *A. xanthophloea*, gall *Acacias* (*A. formicarum* or *drepanolobium*), open "Mbuga" (periodically moist alluvial sunklands), and extensive cultivated areas. Females only appear in their true numbers in open "Mbuga" country. These open areas are considered to be the feeding grounds to which both sexes resort for a meal. Having fed, they are believed to return to the shade of the woods. When savannah shrubs are green and umbrageous, the flies are scattered throughout the bush. When the vegetation is leafless, and later swept by fire, the surviving flies concentrate in their true habitats, the *Berlinia-Brachystegia* communities, and light thickets. Only large game movements cause noticeable effects upon the fly community. They invariably caused a marked increase in the percent of flies caught by man. Among puparia collected from the Kikori bush, 53% of the adults were ♀♀, and the percentage of parasitism by *Thyridanthrax abruptus* was 9.7. When game congregates around certain pools the flies concentrate there. After the pools have dried and the game has left, a concentration of flies continues. The individuals in these centers are ever changing, being recruited from the hungry fly population of the "Mbuga." The flies appear to hunt entirely by sight. The olfactory organs of the antennae are operative only over a very limited field. Olfactory stimuli are believed to produce the reflex of probing. If the antennae are rendered functionless, the fly is less ready to feed. The true habitats of *G. morsitans* coincide with the major breeding sites; they are characterised by perennial, though variable shade, and poor visibility. In the Eastern Kondoa Fly Belt, the *Berlinia-Brachystegia* woods and small thickets form such habitats. These woods are considered to be the centers from which the flies advance or to which they retreat, according to the season. At no season do the feeding grounds form a true habitat. Hungry flies leave the shade of the woods and rove through the open "Mbuga" searching for game. The good visibility of such country is well suited to insects which hunt by sight. It is believed that tsetse flies do not fly through the bush until attracted by a moving object, but that they hunt hosts, following paths and visiting recent haunts of game. Should there be no open country, a road may form a feeding ground. These areas can be recognized by the relatively high percentage of ♀♀ and their starved condition. Females are as abundant as ♂♂ in the true habitats, however they are inactive between meals, and hence are rarely met with. Males are considered to be attracted by movement alone, whereas ♀♀ need this tropism, and hunger also. No evidence can be found to show that a fly community is of a social nature.—*T. A. M. Nash.*

7829. **PAWLOWSKY, E. N., und A. K. STEIN. Experimentelle Untersuchung über die Wirkung des Bisses von Periplaneta orientalis auf die Menschenhaut.** *Arch. Dermatol. u. Syph.* 162(3): 611-620. 7 fig. 1931.—The bite of the upper jaws of *P. orientalis* destroyed the epidermis even as far as the corium. This was followed by dilatation of vessels, slight signs of edema, and foci of inflammatory infiltration. Approximately the same signs appeared after the skin was scarified and an emulsion of the salivary glands applied.

7830. **SHANNON, RAYMOND C. Observations on Anopheles pseudopunctipennis in Peru.** *Amer. Jour. Hyg.* 12(2): 442-448. 1930.—This sp. is apparently the only anopheline in the Rimac Valley and presumably, in view of the very similar topographic and climatic features of the region, the only one occurring, at least in any abundance, on the entire western slope of the Peruvian Andes. It is abundant in certain areas of the valley during certain seasons. The ♀♀ are highly domestic; many were found in the houses at San Bartolomé during Mar. In view of the foregoing, and also of the fact that *A. pseudopunctipennis* is known to be a highly efficient carrier of malaria in northwestern Argentina and has been shown to be a vector in Mexico as well, it may be concluded that this mosquito is probably the sole vector of malaria on the western slope of the Peruvian Andes, and the chief vector at certain altitudes on the eastern slope.

7831. **SHROPSHIRE, JAMES B., and JAMES ZETEK. Unusual Anopheles habitats in the Canal Zone.** *Amer. Jour. Trop. Med.* 7(5): 331-338. 4 fig. 1927.—*A. albimanus* and *A. tarsimaculata* are the chief vectors of malaria in the Canal Zone. Both spp. were found breeding in abundance in a small lake of high salinity. The lake had been formed by a sand barrier cutting off bay water. Larvae breed in the fruit of *Hippomane mancinella,* the "Manzanillo de Playa," the juice of whose leaves and fruit is used for killing fish. Larvae breed in swamps in which the dominant plants are the ferns *Acrosticum aureum* and *A. excelsum.* Occasionally mosquito larvae were found in crab holes. *Anopheles argyritarsis* breeds in tin cans hidden by tall grass. The optimum breding place for this mosquito is in brackish or fresh water, but it can develop in water which is over 50% sea water.

(See also in this issue Entries 7770, 7779, 7785, 7799, 7809, 7814, 8497)

7833. **BREAKEY, E. P. Notes on the natural enemies of the iris borer, Macronoctua onusta Grote (Lepidoptera).** *Ann. Ent. Soc. Amer.* 22(3): 459-464. 1929.—Diptera bred from 100 caterpillars in outside cages were as follows: *Muscina stabulans* (Muscidae), most abundant; *Masicera senilis* (Tachinidae), second in abundance; *Muscina assimilis, Myiospila meditabunda* (Muscidae); *Sarcophaga cimbicis, S. latisterna* (Sarcophagidae). Predatory enemies are *Calosoma calidum* (Coleoptera); the robin, *Planesticus migratorius migratorius;* and insectivorous rodents.—*M. W. Boesel.*

7834. **BREMER, H., und O. KAUFMANN. Die natürlichen Feinde der Rübenfliege. [Pegomyia hyoscyami.]** *Arb. Biol. Reichsanst. Land.- u. Forstw.* 16(3): 520-555. 1 col. pl., 14 fig. 1928.—It is concluded that there are at present no possibilities of biological control of the beet fly. The egg parasite *Trichogramma evanescens* West., the larval parasites *Opius fulvicollis* Thoms., *O. nitidulator* Nees and *Phygadeuon pegomyiae* Haberm., and *Empusa muscae* attacking the adult, played a prominent rôle in the numerical fluctuations of the beet fly in the present situation. A total of 30 hymenopterous parasites is recorded, mostly from the literature. The *Trichogramma* infested 20-30% of the 2nd generation eggs, and was significant only where a miscellaneous stand of vegetation occurred in a relatively small area. *O. fulvicollis* reached a parasitism of 3.7-39.7% in the 3rd generation of the fly in 1924, and passed its life cycle 3 to 4 times in the yr. Eggs are laid in the maggots and adults issue from the puparia. The 1st instar larva is cyclopoid in form. *P. pegomyiae* has 3-4 generations per yr., and generally winters as a mature larvae in host puparia. A few parthenogenetic ♂♂ were reared. *E. muscae* becomes apparent near the end of the flight period of the fly. All the hymenopterous larvae in beet-fly maggots are endoparasitic, and tend to complete their development within the host puparia. *Opius* spp. prevail in the list of parasites. The Proctotrupid, *Trichopria lonchaeorum* Kieff., and the Staphylinidae, *Aleochara bipustulata* L. and *A. bilineata* Gy., were reared from host puparia. Some spp. of secondary parasites are reported. The smaller nymphs of *Lygus pratensis* L. fed on beet fly eggs under observation, and *Anthocoris nemorum* L. seems to prey on larvae as well as on eggs. An acarina and *Haplothrips aculeatus* F. also destroyed eggs. *Formica rufa* L. catches larvae that leave their mines and also inserts its mandibles into the mines and pulls the maggots out. The Anthomyid, *Coenosia tigrina* Fabr., frequently caught beet flies and sucked their blood. Various invertebrates, chiefly birds, destroyed various stages of the pest. These predators are polyphagous, and none are especially restricted to the beet fly. The reestablishment of the earlier ecological complex is scarcely possible but seems to be the only outlook at present for biological control of the beet fly.—*W. V. Balduf.*

7835. **GOURLAY, E. S. Parasites of the subterranean grass-caterpillar.** *New Zealand Jour. Sci. and Tech.* 12(6): 361-362. 7 fig. 1931.—The very injurious grass-caterpillars, *Porina despecta,* have been found to be parasitized by 2 spp. of native Tachinidae: *Hystricia lupina** and *Phorocera clathrata*. H. lupina* is larviparous, depositing the larvae in the sod. The larvae leave the host and pupate in the soil.

7836. **JACOB, C. T. Control of prickly pear by the cochineal insect.** *Nature* [*London*] 128(3220): 117-118. 1931.—Based on successful destruction of *Opuntia dillenii* in S. India by *Dactylopius tomentosus,* the writer suggests its use in S. Africa.

7837. **JAYNES, H. A. Notes on Paratheresia claripalpis Van der Wulp, a parasite of Diatrea saccharalis Fabr.** *Proc. Ann. Convention Assoc. So. Agric. Workers* [*U. S. A.*] 31: 420. 1930.—Abstract.

7838. **OSTERBERGER, B. A. Erax interruptus Macq., an interesting predator.** *Proc. Ann. Convention Assoc. So. Agric. Workers* [*U. S. A.*] 31: 422. 1930.—*E. interruptus* is of economic importance in sugar-cane areas as a predator of white grubs of *Euetheola rugiceps.*

7839. **SIMMONDS, H. W. Noxious weeds and their control in Fiji. Part 2. Biological control.** *Agric. Jour. Dept. Agric. Fiji* 4(1): 29-31. 1931.—Notes on the introduction and preliminary investigation of 3 insects, *Teleonemia lantanae, Liothrips urichi* and a Cecidomyiid, as seed-destroying agencies of *Lantana crocea, Clidemia hirta* and *Stachytarpheta indica,* respectively.

7840. **SMITH, HARRY S., and HAROLD COMPERE.**

An imported parasite attacks the yellow scale. *California Citrograph* 15: 328. Illus. 1931.—*Comperiella bifasciata* (Howard) was successfully established on *Chrysomphalus ficus* in California in 1924 by importation from the Orient but failed to breed successfully on the California red scale, *Chrysomphalus aurantii*. It has been recently found that this parasite will develop on the yellow scale of citrus, *Chrysomphalus citrinus* (Craw), and orchard tests are now in progress to determine the effectiveness of this parasitism.—*C. S. Pomeroy.*

7841. **THOMPSON, W. R. The principles of biological control.** *Ann. Appl. Biol.* 17(2): 306-338. 1930.—Organisms which have a direct specific action on certain others which they habitually injure or destroy may be considered as agents of biological control. Disease-producing organisms naturally become epizootic if conditions are favorable, but if not, the artificial distribution of the causative agent does not make them so. Among the invertebrate parasites and predators, entomophagous insects are the most effective and dependable of the organic checks to insect increase. The regulatory powers of birds and other vertebrates in relation to insect outbreaks are slight. Plant pests, to be controlled by phytophagous insects, must at least be made unable to reproduce or spread, whereas the action of the entomophagous insects need be much less intense in order to exert a perceptible effect as a controlling agent. Biological control has as its objects (1) the intensification of the action of natural enemies present in the area, and (2) the introduction of natural enemies absent from the area. (1) The host may be collected in large numbers and destroyed after the emergence of the parasites, or the population of the entomophagous insect may be artificially increased with the object of immediate reduction in damage by the host. Neither of these methods is likely, according to mathematical proof given, to produce results proportionate to the time and labor expended. (2) The attempt to accelerate the progress of an introduced parasite by liberating additional colonies yr. after yr. may have equally little effect. Parasites having the same effective rate of increase as the host can be helped by liberations but an enormous time is required before any perceptible effect is exerted. Spp. having a higher effective rate of increase than their hosts soon make the effect of repeated introductions negligible. We can encourage such beneficial insects as can be bred easily during periods when they are dormant in nature and their hosts are either dormant or not present in a stage attacked by the parasite or predator reared. Pests arriving from other regions have given rise to the introduction of natural enemies absent from the new home of the host. The establishment of all the primary parasites of an introduced species it is possible to obtain seems advisable. Reintroductions are justified where catastrophic factors have exterminated a beneficial insect. The entomologist may attempt to check a serious indigenous pest by introducing entomophagous insects attacking pests belonging to allied spp. which exist in other countries.—*W. V. Balduf.*

7842. [ZORIN, P. V.] ЗОРИН, П. В. К биологии Microgaster marginatus Nees (Hymenoptera). [Biology of M. marginatus.] Русское Энтомологическое Обозрение. (*Rev. Russe d'Ent.*) 24(3/4): 220-224. 1 pl., 3 fig. 1930.—This sp. is being studied as a parasite for the control of the pests *Polia oleracea* and *P. suasa* in the Leningrad region. The egg, larval stages, and ♀ genitalia are described and figured. Under laboratory conditions, the ♀♀ each produced about 900 eggs in 2 weeks, and 1 ♀ may infect 10 or more individuals of the host.

7843. **ALLISON, J. R. Quantity of oil retained by citrus foliage after spraying.** *California Citrograph* 16: 481. 1931.—Lemon leaves retain more petroleum spray oil than orange leaves; the quantity of oil which may be safely retained is surprisingly small. In ordinary practise 1 cc. of oil is spread over 250 to 1000 leaves, or 1 drop spreads over a minimum area of about 8 × 8 inches.—*C. S. Pomeroy.*

7844. **ARIÉ, JACQUES. O uso da nicotina como insecticida.** *Arch. Inst. Biol. Defesa Agric. e Animal* 4: 121-142. 1 pl., 5 fig. 1931.—A discussion of the composition and qualities of nicotine, and of the great increase in the use of nicotine sulphate and tobacco extract. Brazilian cord-tobaccos are rich in this alkaloid, many containing as much as 10%. The open vessel preparation of extract is condemned. Apparatus is figured and described for decoction in closed vessels.

7845. **BAIER, W. E. Research work on spray oil emulsion and emulsifier.** *California Citrograph* 16: 424-425. Illus. 1931.—Summary of an address. The research department of the California Fruit Growers Exchange has developed a type of jet pump using a specially designed nozzle which is very simple and effective in the "tank emulsification" of cheap petroleum oil or water soluble emulsifiers.—*C. S. Pomeroy.*

7846. **de ONG, E. R., and JOCELYN TYLER. Potassium xanthate as a soil fumigant. II.** *Indust. & Eng. Chem.* 20(9): 912-916. 1928.—Field and laboratory experiments with potassium xanthate as a soil fumigant were made on the beetle *Hippodamia convergens* Guerin and the root knot nematode, *Caconema radicicola* (Greef) Cobb. Potassium xanthate decomposes on exposure in an acid medium yielding CS_2 at varying rates, depending upon the concentration of acid present and the temp. In a neutral medium, decomposition is much slower and frequently fails to give toxicities sufficiently high to be considered practical. The advantages of xanthate over CS_2 alone lie (1) in the high solubility of the salt in cold water, thus permitting the solution to be carried downward into the soil by irrigation water or heavy rains; (2) in the graduated release of CS_2 from xanthate (based upon the formula used), permitting either quick evolution of gas or a slow release over a period of 10-12 days, while CS_2 volatilizes very quickly and dissipates at a corresponding rate except in heavy or in very set soils; (3) and in the greater safety with which potassium xanthate may be used as it has no explosive hazard. Xanthate solutions offer certain advantages over emulsions of CS_2 in that the latter are inconvenient to make and may break before penetrating deeply into the soil. Air samples drawn at varying distances from charges of xanthate and superphosphate showed measurable amounts of CS_2 15-46 cm. laterally, 3-5 days after the sample was placed in the soil. Similar amounts of CS_2 were recovered from the undisturbed sandy subsoil 13 cm. below the sample, but none from the undisturbed adobe subsoil immediately below the decomposed xanthate. Experiments with *H. convergens* showed the highest rate of mortality within the first 48 hr. exposure for a combination of xanthate and superphosphate ($CaHPO_4 \cdot 2H_2O$), the second highest being for combinations of xanthate, superphosphate and sulphur, while the lowest was for xanthate used alone. A gradual decline in toxicity to the beetles occurred when they were placed in the soil at intervals of 5, 10 and 15 days respectively, the mortality having dropped on the 15th day to from 5 to 10% for all experiments. Laboratory experiments with nematodes showed the possibility of 98 to 100% kill in 72-96 hrs. exposure where sufficient superphosphate or HCl had been used to decompose the xanthate. Field

experiments in the control of the root knot nematode gave better results with fall than with spring applications. The most satisfactory formula was 300 lbs. of potassium xanthate and 300 lbs. of superphosphate per acre. Test plants in this plot were 88.2% free from nematodes in comparison with the check showing 45% lightly infested and 36% heavily infested. Potassium xanthate may possibly be used as a practical soil fumigant on crops yielding high profits such as vegetables, citrus fruits and nursery stock. Eradication of nematodes cannot be expected but only varying degrees of control for 1 or 2 yrs.—*E. R. de Ong.*

7849. HOUGH, W. S., and A. B. GROVES. Problems and experiences in removing spray residue from the 1930 apple crop. *Rept. Maryland Agric. Soc.* 15: 220-233. 1931.—Wiping machines (both cloth and brush types) removed 6-86% of the residue on apples. The average removal was only about ¼ of the total residue, which was not sufficient to bring all of the 1930 Virginia apple crop within the world tolerance of .01 gm. As_2O_3 per pound of fruit. Various methods of washing the fruit were employed in many Virginia orchards. When fruit was dipped by hand or floated, as in the paddle washers, in a bath of ½% HCl solution for 1 min., it was cleaned sufficiently to come within the world tolerance. Commercial washing machines equipped with the towel drying units were more satisfactory than machines equipped with air drying systems, because the former proved to be the only means of removing smears resulting from fungicides, dust and such insect residues as leafhopper specking or honey-dew from aphids. It was necessary to heat the acid bath by steam injection when fruit was washed in storage.—*W. S. Hough.*

GENERAL

7856. BITSCHEFF, P. Камчийския конь. [The Kamtschia horse.] Годишникъ но Софийския университетъ, Ветеринарно-медицински факултетъ. (*Jahresber., Univ. Sofia, Vet. Med. Fak.*) 6: 49-78. 1930.—The Kamtschia horse is raised in the mountainous districts of eastern Bulgaria (the so-called Kamtschia region). It belongs to the group of the Arian ["Arieschen"] type, having a straight profile of head. This is a rather small but very strong mountain type of horse with much endurance, usually dark brown or dark red, measuring 126-137 cm. in height at withers, 121-34 cm. in height of back and 124 to 137 cm. in height of loin and 127-140 cm. in body length. The Kamtschia horse is an ideal work animal for mountain areas.—*A. Kalojanoff (transl. by A. H. Kuhlman).*

7857. BÜNGER, H., in Gemeinschaft mit P. BLÖCKER. Mastversuche mit Kälbern. *Züchtungskunde* 5(7): 312-325. 1930.—Fattened to about 100 kgm. live wt., drinking whole milk 3 times daily, 10 calves showed an average daily gain of 1.09 kgm. and required for each kgm. gain 10.9 l. milk. Whole milk yielded a return of 19.9 pfennig per l. Each kgm. of gain required: 0.38 kgm. digestible protein, 1.74 kgm. starch value, 1.40 kgm. milk dry matter. In the 2nd month of life the milk required for 1 kgm. of gain was about 40% higher than in the 1st. In the 1st 3 weeks of life 8 other calves were fed whole milk only and from the 4th week all but 5 l. of the whole milk was gradually replaced by buttermilk, to each l. of which 50 gm. "calf corn sugar" [Kälbermaiszucker] was added. The average daily gain to about 100 kgm. live wt. was 1.06 kgm.; the consumption of whole milk + buttermilk for each kgm. gain, 10.36 l. After subtracting the prices of buttermilk, "calf corn sugar," and the newborn calf, each liter of whole milk yielded a return of 27.5 pfennig. For 1 kgm. gain there was used 1.36 kgm. dry matter, 0.356 kgm. digestible protein, and 1.58 kgm. starch value. The buttermilk agreed with the calves very well. The quality at slaughter was the same as that from whole-milk fattening.—*H. Bünger (transl. by M. H. Keith).*

7858. BURNS, ROBERT H. Wool shrinkage determination by means of small samples. *Amer. Soc. Animal Product. Rec. Proc. Ann. Meet.* 23: 141-203. 1930(1931).—The author concludes that small samples, taking representative handfuls from 50 fleeces, make satisfactory samples for shrinkage tests as far as can be determined by correspondence of duplicate samples. These samples

should always be taken in duplicate. The expectancy is that the duplicate samples will vary less than 2% in shrinkage. Larger differences in shrinkage between duplicate samples were associated with larger differences in commercial grading between the duplicate samples. There was no definite association of larger dirt differences between duplicate and larger shrinkage differences.—*Author's conclusions.*

7860. **CROSS, WILLIAM E. El empleo de la Melaza en la alimentación de los animales. [Use of molasses for stock feed.]** *Vida Agricola* 6(66): 455-462. 1929.—Recommends using molasses as stock feed and describes different methods, giving formulas for daily rations for different animals; also treats of manufacture of molasses feed.—*W. E. Cross.*

7861. **DARLOW, A. E. Factors that affect the quality of wool.** *Amer. Soc. Animal Product. Rec. Proc. Ann. Meet.* 23: 195-196. 1930(1931).—The author found a positive correlation between diam. and length of 0.10-0.55; a negative correlation between diam. and crimp of 0.05-0.87; a positive correlation between diam. and breaking strength of 0.25-0.82; a negative correlation between crimp and stretch and crimp and breaking strength; and a rather large positive correlation between stretch and breaking strength.

7862. **DESSOMVIELE, R. Veevoeding en productiewaardeeenheden. [Stockfeeding and productive value units.]** *Onze Ploeg [Louvain]* 9(10): 308-314. 1930.—A comparison of the various units of productive value of feeds, proposed during the last half century (Thaer's hay value; the Scandinavian "feed unit"; Wolff's carbohydrate value; Kellner's starch value; Hansson's milk value; Armsby's net energy value) indicates that, for stock feeding, 1 therm = 1.000 cal.; 1 feed unit = 1.650 cal.; 1 kgm. starch value = 2.365 cal.; and, for milk production, 1 feed unit = 2.100 cal.; and 1 kgm. milk value = 2.800 cal.—*R. Dessomviele.*

7863. **DUERDEN, J. E., and EVLYN BOYD. The blackhead Persian. A primitively-coated fat-rumped sheep.** *Union So. Africa. Dept. Agric. Bull.* 82. 1-46. 26 fig. 1930.—The Blackhead Persian, indigenous to Somaliland and Arabia, was introduced into South Africa recently where by selection it has become raised into a distinctive breed with fixed characteristics. The Stud Book qualifications are given. Its manner of introduction is traced and the general characters of the breed are given. The most distinctive are the pure black head and neck and the dull white body; also, the marked deposition of fat around the tail and hind parts of the body. The salient features of the farming of the Persian are described, and also experiments in crossing with the Merino and Suffolk. During the fetal stage the tail is long, with small pads of fat down each side, when it resembles that of the fat-tailed sheep, such as the Karakul, Afrikander and Woolled Persian. The fat-rumped condition is therefore a later development, but the fat-tailed stage reappears in the fetus of each individual. The covering of the Persian is primitive and ancestral, resembling that of wild sheep, and comprises an outer coat of coarse medullated fibers, the kemp, and an inner coat of fine wavy fibers, the wool. On account of its primitive nature it serves as a basis for a study of the evolutionary changes, which have taken place in the coat of the many different breeds of domestic woolled sheep. Four distinctive types of fibers occur in the coat: (a) Kemp, coarse and medullated; (b) Wool, fine and mostly non-medullated; (c) Heterotypes, kempy above and woolly below; (d) Gare, intermediate in thickness between kemp and wool and medullated. Kemp fibers constitute the definitive covering of the Persian, and are distributed over the whole body, varying in length in different regions. They are stiffly wavy in 1 plane, overlapping and inclined backwards, and give a smooth surface to the body. The wool occurs as an entangled irregular mass of fine wavy fibers round the lower part of the kemp, not grouped into tufts or staples as are the fibers in woolled sheep generally. It is best developed over the shoulders, back and sides and very sparse elsewhere, but varies in amount with climatic and other conditions. The individual fibers are approximately circular in section in contrast with the oval form of the kemp; some of the thicker fibers show a feeble discontinuous medulla. All fibers, both kemp and wool, have at first long solid tapering tips. Within a few months of birth these begin to break off in successive short fragments, leaving the fibers with smooth or jagged truncate ends. The small fragments fall away, not accumulating at the surface, as in the denser coat of the Merino. The coat undergoes complete seasonal shedding towards the end of the winter. The kemp fibers are mostly thrown off separately, while the wool as a whole forms a dense mat with some entangled kemp. Two stages are represented: the liberation of the fibres from the socket; and their passage to the surface. Prior to shedding a copius exudation of yolk takes place. The lamb is born with the kempy coat well developed and with only a small quantity of wool, and in the fetus the kemp fibers appear prior to the wool. The direction of the fibers is similar to that in the adult, the whorls on the sides of the body and in the axillary and inguinal regions being distinct. The coat of the lamb passes insensibly into that of the adult, no marked change in the nature of the constituent fibers taking place. The tapering tips of the fibers are angulated, giving a sickle- or whip-like appearance, due to the fact that the growing fibers do not emerge from the socket directly, the tip traversing the epidermal layer for some distance. The physiological readjustments consequent on birth and exposure leave an impress on the growing fiber, a slight narrowing taking place in the part grown immediately following on birth. In all woolled sheep the coat has undergone departures from the primitive condition represented in the Persian. In the main these consist in a reduction in the importance of the kempy coat and an increase in that of the woolly coat, though in the Mountain Breeds the heterotypes have increased in significance. The more primitive stage however tends to be repeated in the early lamb, the transformation taking place later. In the best-bred-Merinos the kempy coat may wholly disappear in the adult, the fleece then consisting of pure wool fibers. The evolutionary changes also involve a reduction in coarseness of the kemp fibers and an increase in the thickness of the wool, compared with those of the Persian and other wild sheep. Despite domestication for a long period, the coat of the Persian has in no way undergone any evolutionary change. The modifications in the domestic woolled sheep must be the result of germinal mutations, not of domestication in itself. Selective breeding in the woolled sheep aims at the complete elimination of kemp, and at the higher quality and greater uniformity of the wool. By contrast, selection in the Blackhead Persian is directed towards improvement in the conformation of the body, and has resulted in its recognition as a standardized breed.—*Authors' summary.*

7864. **FILIPOVIĆ, STJEPAN. Konstrukcija kravljeg vimena i omjer izlučenog mlijeka u prednjim i zadnjim njegovim čertvrtima. [Formation of the udder and the ratio of milk secreted in front and hind quarters.]** *Gospod.-Šumarski Fakult. Sveučil. Kraljev. Jugoslavije u Zagrebu, Spomenica Fakult. Savjeta (Fac. Agron. et Forest. Univ. Roy. Yougoslave Zagreb, Mém. Cons. Fac.)* 1919-1929: 532-536. 1929.—The udder of the cow is formed according to mathematical laws, especially the law of the geometric mean. This relation exists between the dimension of the two front and hind quarters and also between the breadth and height of the front half as contrasted to the rear half. The breadth of the front (s^1) and hind (s^2) quarter of the udder show the ratio $s^1 : s^2 = 5 : 3$. The height of the front quarter (v^1) and hind quarter (v^2) are in the relation $v^1 : v^2 = 5 : 3$, while the length of the same quarters vary in the ratio $d^1 : d^2 = 4 : 5$. The relative milk volumes are in the ratio $V^1 : V^2 = 4 : 5$. This is an average or general rule with many exceptions. As many as 16% of the cases showed less

secretion in the front quarters than in the hind and 5% of the cases showed the same amount of milk secretion in both. The fact that in a great majority of cases the 2 hind quarters secreted about 25% more milk than the fore-quarters is of considerable practical importance.—*Author's summary (transl. by J. L. Lush).*

7865. HANSSON, NILS, H. EDIN, och SVEN BENGTSSON. Betydelsen av majsens finfördelning och stöpning vid utfodring av gödsvin. [On importance of fine milling and steeping of maize for fattening pigs.] *Meddel. Centralanst. Försöksväs. Jordbruksområdet* 385. 1-42. 1930.—The bulletin reviews experiments concerning the ability of pigs, especially, to utilize grain ground to different degree of fineness and also soaked, cooked and fermented grain. Also, detailed account is given of very extensive Swedish experiments with corn. Crushed grain was utilized 5-6%, coarse ground grain 10-12 and fine ground grain 15-18% better than whole grain. Cornflakes seem to have the same value as fine ground corn. Soaking for 24-28 hrs. has not influenced the digestibility, nor has fermenting of the grain, whereas cooking has increased the digestibility a little but not to such a degree as to pay the expense. Even when the daily allowance of corn was gradually increased to 75% of the concentrates no bad influence on the firmness of the pork could be observed. Dairy offals were fed plentifully as a supplement. Fine ground dry corn was easier taken in by the pigs than coarse ground corn whereas soaking fine ground corn in warm dairy offals rendered the intake more difficult. Good agreement could generally be observed between the results of the digestibility trials and those of the practical feeding experiments, which fact enhances the confidence in the 2 methods for ascertaining the effect of feeding stuffs.—*N. Hansson.*

7866. HENRY, MAX, and E. A. ELLIOTT. Sheep lick trials at Glen Innes [N. S. Wales]. *Agric. Gaz. N. S. Wales* 42(5): 390-397. 1931.—Trials testing 3 kinds of licks were carried out with 4 lots of sheep of 80 Merino ewes each. As regards fertility, results were as follows: Group A—receiving Cystine Os, 80%; group B—receiving bone meal, 90.41%; group C—receiving iodine, 85.3%; and group D—receiving no lick, 80.54%. Group A gave the greatest percentage of samples showing change in growth with 88%, group D being least with 66%. In each group a certain amount of unsound wool was found. Group A showed the greatest amount of unsoundness. So far as the maintenance of weight of adult sheep is concerned, there is no advantage in providing any of the three licks when sheep are run under the conditions and on the country on which the experiment was conducted.

7867. HENSLER, KURT. Die Ziegenzucht in der Pfalz. Entwicklung und heutiger Stand. Volkswirtschaftliche Bedeutung der Ziegenzucht. *Landwirtsch. Jahrb. Bayern* 20(12): 738-747. 1930.—The goat utilizes feeds most economically of all domestic animals. Anemia from the use of goat's milk is due to excessive and unbalanced use. The social, industrial and agricultural (peasant farming) organization of the Palatinate is the basis for an extensive goat industry, and virtually makes goat raising a necessity. White hornless Saanen-type goats are most numerous. They are the result of crossing the native goat, representing the mixing of German, Celtic and Moor ("Torf") goats, and the original hornless Saanen goat. For a long time there was opposition to the goat in the Palatinate on account of its injurious effect on forests as is shown by government regulations of 1738, 1769 and 1791. Advancement in goat breeding began about 1890. The goat registry association of the Palatinate represents 60% of the industry. Approval of males used for breeding is compulsory. They are owned by the society and loaned to members. Prices of goats rose enormously during the world war and retarded progress about 10 years. Most of the growth of the ♀ is attained at the end of the first yr. and of the ♂ at 2 yrs. The goat of the Palatinate is not yet fixed in type and body measurements vary considerably. Well developed ♀♀ are 75-76 cm. high at the shoulders, have medium to strong rumps, strong constitutions, and good health. Milk yield is about 700-800 liters, and the dressing percentage is 56-58%. Deteriorations observed near the close of the 19th century were the results of faulty care and management, combined with inbreeding without selection. Improvement has been obtained through organization of the herd book, performance tests, development of the goat breeders' society, financial support of government, agricultural and community organizations, and information for the breeder on proper feeding, management and breeding.—*K. Hensler (transl. by A. H. Kuhlman).*

7868. HONCAMP, F., W. SCHRAMM, und H. STOTZ. Weitere Untersuchungen über die chemische Zusammensetzung und den Nährwert von Gelbhafer und Weisshafer. *Zeitschr. Tierzücht. u. Züchtungsbiol.* 11(3): 433-444. 1928.—Analyses and digestion experiments with sheep indicate no significant differences among the 4 kinds of oats examined. The feeding value was slightly higher when the oats were coarsely ground than when fed whole. Percentages of digestible nutrients reported for the 4 kinds of oats: Crude protein 9.12, 11.66, 7.63, 10.84; true protein 8.35, 10.71, 7.07, 9.81; N-free extract 53.57, 52.49, 55.82, 54.58; ether extract 5.57, 5.26, 5.24, 5.59; percentage of digestible nutrients in the crude fiber, 2.23, 4.09, 2.74, 3.12.—*M. H. Keith.*

7869. HUGHES, E. H. The relation of nutrition to necrotic enteritis in young growing pigs. *Amer. Soc. Animal Product. Rec. Proc. Ann. Meet.* 23: 237-242. 1930 (1931).—Pigs fed the basal ration (rolled barley, 83%; tankage, 7%; linseed oil meal, 3%; chopped alfalfa hay, 5%; precipitated $CaCO_3$, 1%; NaCl, 1%) recovered rather quickly from a condition known generally among pork producers as necrotic enteritis. The addition of $CaCO_3$ (1%) to a ration of rolled barley and salt, which contains a high P content, resulted in this instance at least, in complete recovery.—*Author's summary.*

Goettsch.*

7871. KUROSAWA, R. Über die Frühdiagnose der Trächtigkeit bei der Stute durch vaginale Untersuchung, insbesondere durch Untersuchung von Scheidenschleim. [Early diagnosis of pregnancy in mares by investigation of the vagina, especially by investigation of the vaginal mucus.] *Tierärztl. Rundschau* 37(20): 345-348; (21): 361-365. 8 fig. 1931.

7872. LANDIS, J., und H. BURCKHARDT. Schweinemastversuche mit "Provendéine." *Landwirtsch. Jahrb. Schweiz* 44(3): 369-382. 1930.—Large claims in advertisements in the farm press have been made for "Provendéine," a supplementary feed preparation which is said to stimulate the appetite of pigs, to aid digestion, and to bring about rapid growth and fattening. It is claimed to have antirachitic properties and to stimulate remarkable development in both unthrifty and normal pigs. Special virtues were said to be due to enzymes present in this material, especially diastase, but also minerals and vitamins, the latter due to treatment with ultra violet light. "Provendéine" was found to be made up of rice and corn meal, dicalcium phosphate, and calcium carbonate, with additional aromatic principles. Enzymes were claimed to have been added and the whole material irradiated. The gross analysis proved to be 9.1% water, 32.0% ash, 8.5% crude protein, 6.8% fiber, 39.1% N-free extract, and 4.5% fat. On the basis of authors' investigations in which practical swine rations were supplemented with "Provendéine," it proved uneconomical and they are unable to recommend to swine growers the use of "Provendéine" as supplied to them by the manufacturers. The original firm meanwhile went into bankruptcy but the successors have announced that "Provendéine has recently been markedly improved and much smaller dosages are now permissible." This latest

product, sold under the same name, is to be tried out in a similar manner.—*G. Bohstedt.*

7873. **MANGOLD, E., und W. LINTZEL. Über die Jodfrage in der Tierernährung.** *Mitteil. Deutsch. Landw. Ges.* 45(28): 615-616. 1930.—In goitrous regions, human beings can best be protected by common use of iodized salt containing 0.5-1 gm. KI per 100 kgm., the amount being controlled by a central agency. Domestic animals might also be protected by use of salt containing the amount of I normally present in their feeds in non-goitrous regions, namely 1-2 gm. KI per 100 kgm. This should also be controlled by a central agency. The suggestion for increasing the milk production and the I content of the milk by feeding large amounts of I to dairy cows is opposed, because possibly dangerous to the cows and surely uncertain as to the amounts to be used and the results to be expected. Considering that even slight excess of I beyond the needs may work injuries, such milk of high I content might become a public danger.—*M. H. Keith.*

7874. **NORDBY, J. E. Quintuplet lambs, an unusually large family.** *Jour. Heredity* 19(9): 384. 1 fig. 1928.—A record of a Rambouillet × Cotswold cross-bred ewe which dropped 5 lambs at 1 birth, all alive and vigorous. She had previously given birth to twins.—*L. M. Dickerson.*

7875. **PAWSON, H. CECIL. Sheep breeding in Northumberland.** *Jour. Min. Agric.* [*Gr. Britain*] 36(12): 1152-1158. 5 pl. 1930.—About 1 sheep per acre of pasture is maintained. Border Leicester, Cheviot, and Scotch Blackface breeds are used. Border Leicester rams × Cheviot and Blackface ewes progeny are called "Half-bred" and "Mules" respectively. After using Oxford Down, Border Leicester, Ryeland, Hampshire, Suffolk, Oxford × Border Leicester and Suffolk × Border Leicester rams on these first cross ewes at Northumberland Experiment Station, the present practice is to use Oxford rams with Half-bred ewes and Suffolk rams with Mule ewes, all lambs being fattened and sold.—*B. L. Warwick.*

Pr. $6.—Of biological interest are the chapters dealing with the uses of dried milk in human and animal feeding; digestibility of dried milk and the microbiology of dried milk.

7877. **RAETZELL, HERMANN. Die Entwicklung der Rindviehzucht und Rindviehhaltung im Bezirk Hildesheim.** 126p. Dissertation, Landwirtsch. Hochschule zu Berlin, 1928.—Climatic and soil conditions, yield of leading crops, and size of farms in the district of Hildesheim, Hanover, have been favorable for the development of the livestock industry. The development during 1764-1864 indicates that considerable attention was given to feed utilization by the various types of cattle raised in the region, which were used for milk, meat and work. The effects of the World War exerted a tremendous influence on the cattle industry. From 1919 to 1925 consistent gains have been recorded in the number of cattle in all sections of the district. Comprehensive measures have been devised to encourage the production of better cattle for both beef and dairy purposes. These are concerned with the control and eradication of diseases, especially foot and mouth disease and tuberculosis, the introduction of good sires, the rigid selection of all breeding animals, the records of production for determining performance, the use of better rations, a better knowledge of type through judging demonstrations, the establishment of public shows and markets for breeding animals. —*A. H. Kuhlman.*

7878. **RICHTER, K., K. E. FERBER, und K. CHRZASZCZ. Ein weiterer Beitrag zur Frage der Roggenfütterung an Schweine.** *Mitteil. Deutsch. Landwirtsch.-Ges.* 45(38): 804-806. 1930.—The question whether rye is adapted for use as the sole grain for fattening swine only in combination with protein feeds was studied on 2 groups of 10 and 11 young fattening swine, of which one received potatoes, the other rye as the principal fattening feeds. Rye proved non-injurious; it was tolerated as the principal feed. The rye group was not quite equal to the potato group at slaughter, but the difference was within the limit of error. The additional slaughter tests showed that the swine fed rye yielded a very good quality of flesh and fat (lard, bacon(?)).—*K. E. Ferber* (*transl. by W. E. Joseph*).

7879. **SAITO, M. On the dialyzable nitrogen of fresh milk.** [In Japanese, with English summary.] *Bull. Myazaki Coll. Agric. & Forestry* 3. 1-7. 1931.—When the dialyzate is concentrated into syrup in vacuum at low temp., some unknown nitrogeneous substances (constituting 2.3-2.8% of total N of milk) can be precipitated by phosphotungstic acid. They show strong ninhydrin reaction, but no biuret reaction or ordinary protein reactions. Of this diffusible N, ¼ exists in amino-form and the remainder in combined form; very small amounts of free ammonia are present (0.02-0.06% of total N of fresh milk). When milk is heated to boiling for 30 min. the ammoniacal N increases relatively. When milk is subjected to lactic fermentation, the amount of the diffusible N increases at a very slow rate but the N distribution is completely changed in the dialyzate; the combined portion of N disappears, being decomposed into ammoniacal and amino N. Irradiation with ultra-violet for 2½ hrs. does not change the amount or distribution of diffusible N. When milk is coagulated by rennet, a part of its diffusible N is absorbed in the coagulum.—*From author's summary.*

7882. **SPILDO, LARS S. Vurdering av melkekyr. En kort sammenligning av forskjellige maleenheter. [Evaluation of milk cows. Short comparison of various methods.]** *Nordisk Jordbrugsforsk.* 1930(6): 398-410. 1931.—The author begins with a review of the factors that have greatest influence on milk production. He divides them into 2 groups: The physiological, and the breeding or genetic. Two viewpoints, the economic and physiological, are, as a rule, unfortunately associated in practise. The milk value in human and stock feeding is based upon its content of energy and fat. The author draws comparisons among the different systems of expressing the milk value: those of Møllgaard, Sandmann and Overman, Gaines and Davidson, and the system used in Scandinavia. He discusses the suitability of these systems under the different conditions, in order to show the effect of the feed given to the cow. He finds that the only usable method for that purpose is that which expresses the energy content in the milk.—*L. S. Spildo.*

7883. **STOUTAMIRE, RALPH. Goats in Florida.** *Dept. Agric. Florida Bull.* 37. 6-28. 14 fig. 1930.

7884. **THOMPSON, C. P. Preparation of darso for fattening hogs.** *Amer. Soc. Animal Product. Rec. Proc. Ann. Meet.* 23: 232-234. 1930(1931).—Tests with 6 lots indicated that grain sorghum heads can not be successfully fed to hogs and that grinding decreases rather than increases their feeding value, no doubt due to the fact that the heads contain an excessive amount of crude fiber which the hogs are unable to separate from the grain when finely ground.—*Author's summary.*

7885. **WASHBURN, R. M. Productive dairying.** (Lippincott's Farm Manuals, edited by K. C. DAVIS.) 4th rev. ed. 438p. 133 illus. J. B. Lippincott: Philadelphia, 1931.

7886. **WOOD, D. R., E. T. ELLING, and A. E. FLETCHER. The diphenylamine test for nitrates in milk as a means of detecting added water, and the effect of drenching cows with "nitre."** *Analyst* 56(661): 248-249. 1931.—No samples of genuine milk have been positive for nitrates, even after drenching cows with "nitre"; the test has detected as low as 5% of added water containing 0.5 part per 100,000 of N as nitrates.

7887. ZORN, W., K. RICHTER, und K. E. FERBER. Über eine Methode die Festigkeit eines Specksobjectiv festzustellen. *Züchtungskunde* 4(10): 457-462. 2 fig. 1929.—The Mangold sclerometer is described as used to measure the hardness of bacon. By means of a lever arm a scale shows the distance to which a rod penetrates the bacon under a given load. Uniform, perfectly rectangular blocks $6 \times 2.5 \times 2$ cm. were cut, always from the same part of the side of bacon, and tests were made at 16-18° with the block on its broad face and on its long side. In each position 5, 10, and 20 g. loads were applied 1 cm. from each end and midway between the ends. These values are reported for 56 samples together with the "hand grades," the I numbers, and the saponification numbers for the bacons. The "hand grades" are rather indefinite, but of the 3 objective methods of judging the hardness only the sclerometer method could replace them.—*M. H. Keith.*

7888. ANONYMOUS. Atlas international zootechnique. 1. Atlas international des bovins. Allemagne. Hongrie, Pays-Bas, Suisse. (International cattle atlas. Germany, Hungary, Netherlands, Switzerland.) Bestetti & Tumminelli: Rome, 1930.—The work consists of maps showing the distribution of cattle breeds, varieties and strains, and density of stocking in the various countries and continents, with text in English, French and German, discussing climate, soil, agriculture, cattle breeds, breeding and breeding conditions and economic factors for each geographic unit.

POULTRY

7889. ANGHI, CSABA GEYZA. Az "Y-O" hatása a baromfi fejlodésére. (The influence of the "Y-O" on the development of poultry.) [With English summary.] *Mezögazd. Kutat.* 2(9): 381-401. 1929.—"Y-O," a preparation containing vitamines A, B, and D, was added to the ration of 3 groups of poultry. One group (I) was maintained as a control, group (II) received 2% "Y-O," and group (III) 5% in the food. Groups I, II, and III, contained only normal birds. Group IV, which consisted of poorly developed birds, got 5% of "Y-O." At the end of the experiment, group III showed the best growth namely, a total increase of weight amounting to 4365 gm. The growth rate diminished with increasing age; but in spite of this the increase in weight of group III was 2220 gm. at the 2nd mo. of the experiment,—75 gm. more than in the 1st month. The growth rate was much greater in cocks than in hens. 5% of "Y-O" accelerated feathering very little. The body measurements expressed in % were the best in group I. The length of the thigh was greatest in the cocks and hens of group III. The food was utilized best in this group; this group ate the least food except the normal ones (12000 gm.), and gave the greatest increase. A dose of 2% of "Y-O" has only a slight effect on development. The development of group IV was bad at the beginning of the experiment. The influence of "Y-O" was considerable in this group. The development of the normal poultry growth is favourably influenced by giving 5% "Y-O" in the food.—*From author's summary.*

7890. ATWOOD, H. A study of the time factor in egg production. *West Virginia Agric. Exp. Sta. Bull.* 223. 11p., 1 fig. 1929.—172 White Leghorn pullets were trapped hourly beginning at 8 a. m. and ending at 5 p. m. during the month of August. 1 yr. later the same birds were trapped in a similar manner. The data showed: The longer the cycle the shorter are the intervals between the laying of successive eggs. The interval between the laying of the last 2 eggs in a cycle is usually greater than any other interval in the cycle. The intervals at or about the middle of the cycles are shorter than the intervals at either extremity. As the birds become older the intervals between the laying of successive eggs become longer. The shorter average intervals between the laying of successive eggs are usually associated with the better layers. The regularity with which birds lay later and later on successive days affords means by which trap nest records may be checked with a high degree of accuracy when the time of laying is recorded for each day.—*H. Atwood.*

7891. BUCKNER, G. DAVIS, J. HOLMES MARTIN, and W. M. INSKO, Jr. Some chemical factors governing egg formation in hens. *World's Poultry Congress* 4(Sect. B): 330-333; résumé sect. 40-41. 1930.—The conditions governing the formation of eggs in hens are briefly discussed and attention is called to some of the chemical reactions entering into the nutrition of the hen and the formation of eggs. The H ion concentration of the separate divisions of the alimentary canal and their contents are given and discussed. The percentage of calcium in the venous blood leaving the intestines of laying hens is larger than that of the arterial blood going to the intestines. The percentage of Ca in the blood of the left ventricle of the heart of the same hen is intermediate between these two values. When laying hens that were fed a yellow corn-skim-milk-calcium carbonate ration were deprived of the calcium carbonate, the average number of eggs laid, the average weights of the eggs and egg shells, and the average content of Ca in the blood became smaller as the experiment progressed. This decrease in the concentration of Ca in the blood may be associated with the lowered hatchability of eggs produced under the same conditions. The H ion concentration of the mucosae of the various sections of the oviduct, of the albumen found in the albumen-secreting section, and of the uterus was determined. The difference in the acidity of the mucosae of the various parts of the oviduct suggests an association with the secretion or formation of the shell membrane and egg shell. The possible means of depositing the calcium carbonate of the egg shell are discussed.—*Authors' summary.*

7892. ELMER, ROMA C., FRANK C. HILBERG, and PAUL E. HOWE. A study of squab and pigeon flesh particularly with regard to the distribution of protein. *World's Poultry Congress* 4(Sect. B): 278-284; résumé sect., 34-35. 1930.—The results indicate more nitrogen (protein) and less water in pigeon flesh than in squab. There is approximately the same amount of total soluble N and only a slightly higher amount of non-protein N in the case of the squab, therefore, a higher percentage of total soluble protein N (total soluble N minus non-protein N). A greater amount of insoluble N, i.e., connective tissue and outer layer of fibres, was found in the pigeon than in the squab. This difference was borne out by personal observations of the toughness of the breasts of pigeons, as compared to squabs. No definite differences in the distribution of the various protein fractions, para-myosinogen, myosinogen and albumin, was observed although the average results indicate a slightly higher proportion of globulin I and a lower proportion of globulin II in the squab. Data are also presented on the distribution of the various edible portions of the carcass of squabs and pigeons, which show that the percentage of breast muscle and of total edible material is lower in squabs than in pigeons.—*Authors' résumé.*

7893. HAGEDOORN, A. L. Different ways in which a geneticist can co-operate with poultry breeders. *World's Poultry Congress* 4(Sect. A): 116-119; résumé sect., 13-14. 1930.—The following lines of theoretical work are of interest to breeders; Genetical analysis of differences, including sex; correlation studies as an aid to selection for productivity; study of inbreeding and heterosis; inheritance of disease resistance; inheritance of differences in productivity and hatchability. The following are suggested as branches of practical work which might be done in cooperation with breeders: production of new breeds by adding a genetic factor to an established breed; establishing a new recessive variety of an established breed; experiments with hybrids and their progeny; teaching principles of genetics to breeders, journalists and official advisors; establishment of a consultation bureau for applied genetics; cooperation with

officials in devising improved systems of laying tests.—*Author's summary.*

7894. **HANSSON, NILS. The nutrition of egg-laying hens.** *World's Poultry Congress* 4(Sect. B): 268-277; résumé sect., 34. 1930.—The animal husbandry section of the Swedish Agricultural Experimental Station at Stockholm has found that Swedish limestone gravel is not a suitable substitute for imported mollusc shells as the source of mineral food for shell formation. Treatment of chickens with ultraviolet light increased their food consumption and growth, but increased the food consumption per kg. of growth (1% of cod liver oil was mixed with the ration). The general nutritive requirements of hens were shown to be dependent mainly on the intensity of egg production, but also upon the weight of the hens and the time of yr.—*Author's summary.*

7895. **HEUSER, G. F., and L. C. NORRIS. The influence of the protein level on the rate of growth in chickens.** *World's Poultry Congress* 4(Sect. B): 307-316; résumé sect., 38. 1930.—A study of the rate of growth of chickens shows that the % rates of gain begin very high, with an average of 40.4% for the first 4-week period, which decreases during the following 4-week periods to 22.9, 13.9, 7.0, 5.8, and 3.5% resp. At the end of 24 weeks, these birds had not yet reached maturity, but their rate of gain was small. In order to get maximum results in early growth in chicks, it is necessary to furnish a ration with a fairly high protein content. Conversely, by limiting the amount of protein, it is possible to restrict growth. The results of several experiments indicate growth up to 8 weeks in the expected order, according to the protein level, up to about 20%. Theoretical curves showing rates of gain up to 20 weeks portray normal growth as represented by a 2-moment parabola having the formula $y=a+bx+cx^2$. Early sub-normal growth may be compensated for and the same mature weight attained if the protein level later becomes adequate. There is probably a level of protein below which one cannot safely feed, because of such severe stunting that it is never entirely overcome. The chicks on lower protein rations do not show greater gains than the normal lots until the periods of greatest actual gain are past, in the present data (for pullets) at about 10 weeks of age. Growth and accompanying protein requirements may be divided into 3 periods. (1) the first 6-8 weeks, when growth is rapid and a high protein level needed; (2) from the end of the 1st period to 12-14 weeks, when growth is less rapid, and the protein level can be decreased; (3) from the end of the 2nd period to the end of the growing period, when growth is further decelerated, and the protein level can be again decreased.—*From authors' summary.*

7896. **KNANDEL, H. C. The confinement method of poultry and turkey management.** *World Poultry Congress* 4(Sect. B): 334-341. 2 pl.; résumé sect., 41-42. 1930.—From experimental data the following conclusions are drawn: Eggs from fowls reared and maintained in confinement for 3 generations hatch very satisfactorily. Chicks hatched from eggs laid by fowls reared and maintained in confinement make uniformly good growth. Mortality for chicks raised in confinement is low. All fowls possess deep yellow pigmentation throughout the rearing period and at maturity. When fowls are raised by this system, less land is required. No tape- or round-worm infestations in the intestines, but isolated cases of cecal worms, have been observed. The flesh of fowls reared in confinement is of excellent table quality. The mash and grain consumption per Single Comb White Leghorn and Barred Plymouth Rock pullet for the first 24 weeks was 19.67 lb. and 22.78 lb., respectively. The confinement method of rearing chicks is not advocated except in cases where poultrymen have experienced great difficulty in rearing chicks on range due to round- and tape-worm infestations. The rate of growth obtained in turkeys was greater than that reported by other investigators. The mash and grain consumption per bird for the first 24 weeks was 58.05 lb. and 56.12 lb. for the Bronze and White Holland varieties respectively. As the birds approached maturity, the pounds of feed required to produce a pound of gain increased from 2.56 to 7.71 lb. The protein intake remained at a high level until the 18th week, varying around 20%. From the 18th to the 24th weeks, the level decreased from 20.2% to 14.8%. More than 93% of all turkeys started were raised to market age. The loss from blood and feather dressing for males was 9.5%, for females 10.4%. The full drawn birds showed a shrinkage of 24.2 and 24.7% for males and females respectively. These differences are due to size, not to sex. Excellent market birds were produced in complete confinement.—*Author's summary.*

7897. **LOMAX, ERIC B. Some protein feeds for poultry.** *World's Poultry Congress* 4(Sect. B): 241-244; résumé sect., 28-29. 1930.—The value of several protein supplements for egg production by White Leghorn pullets was investigated. The feeds tested were meat meal, meat meal with minerals, extracted soy bean meal with minerals, decorticated extracted peanut (*Arachis*) meal with minerals, and fish meal. Tentative conclusions drawn from the 2 yr. work indicate that no statistically significant differences were obtained in egg production among the pens tested. Present indications lead us to believe that a variety of protein foods in rations for poultry gives more economical returns than those obtained from a single protein concentrate. This is attributed to the greater selection of amino acids upon which the fowl is able to draw for its needs.—*From author's summary.*

7898. **PRENTICE, J. H., R. G. BASKETT, and G. SCOTT ROBERTSON. The nutrition of the chick and its effect on growth, maturity, egg production and mortality.** *World's Poultry Congress* 4(Sect. B): 224-233. 1 graph.; résumé sect., 26-27. 1930.—Experimental work with White Wyandottes shows that the best growth and rearing results are obtained when a mash of mixed cereal feeds is supplemented by separated milk to drink, and that, compared with a similar mash, but with water to drink, the birds are more than twice as heavy when 13 weeks old, and mature at about 137 days, compared with 186 days in the latter case. Attempts to improve the ration of mixed cereals and separated milk to drink by the addition of protein-rich and mineral feeds resulted in no substantial increase in growth rates. A mixed cereal mash to which was added 18% of extracted soy bean meal and 3½% of a mineral mixture (based on the minerals in milk) in a number of trials gave results comparable to those obtained with the milk ration. The chicken-rearing mortality rate varies between 20 and 5%, depending upon the type of the ration. The higher the plane of nutrition, and as a consequence the quicker the rate of maturity, the lower the mortality. Pullets reared on a ration which induces most rapid growth and earliest maturity mature at the heaviest weights and give the best egg performance in their pullet year. Maturity is mainly a function of the mineral, and not the protein content of the ration. Withdrawal of the mineral portion of the ration slows down the rate of maturity while the complete withdrawal of protein-rich feeds has no influence on the age at maturity, but does lead to a reduction of weight then. The ration inducing the most rapid growth and maturity has the further advantage of enabling the surplus cockerels to be disposed of, fat, at a much earlier age.—*From authors' summary.*

CROP SCIENCE (ARVICULTURE)

7899. **ÅKERMAN, Å. Några synpunkter att beakta vid valet av höstvetesort.** [Some ideas with regard to selection of winter wheat varieties.] *Landtmannen Tidskr. Landtmän* 13(33): 717-718. 1930.

7900. **[BARANOV, A. I.] БАРАНОВ, А. И. Опыт климатической характеристики новых хлопковых районов в Крыму.** [Climatic characteristics of new cotton regions in Crimea.] [English summary.] Бюллетень Государственного Никитского Опытного Ботанического Сада. (*Bull. Gov. Bot. Gard. Nikita, Yalta, Crimea*) 6. 5-34. 1930.—Cotton growing in Crimea and a critical survey of the climate of this country are discussed. Cotton can be grown successfully only in the southern parts of the peninsula at Kertch and in the coastal parts of Simferopol and Eupatoria regions. In the more northern parts of Crimea the temp. of early and mid-August is generally too low and the decrease of temp. in September and October is too rapid for successful cotton cultivation.

7901. **BORODIN, D. N. Russian field crops in the United States.** *Proc. Internat. Congress Plant Sciences, Ithaca, N. Y. 1926.* 1: 61-86. 9 fig. Geo. Banta Publishing Co.: Menasha, Wisconsin, 1929.—The history of plant immigration from Russia has had 3 distinct periods: (1) importation of seeds by Russian immigrants, (2) the sending of special expeditions to Russia for collecting Russian seeds and plants, and (3) selection and hybridization of Russian varieties at American Agricultural experiment stations. It would be difficult to estimate exactly the contributions made by immigrants and explorers. The author divides the field crops introduced into the U. S. A. into the following 10 groups and in many instances gives the origin, description, and adaptation of specific varieties and the extent to which they are grown in this country, (1) hard red spring wheats, (2) hard red winter wheats, (3) Durum wheats, (4) rye, (5) oats, (6) broom corn and proso millet, (7) flax, (8) Russian sunflower, (9) alfalfa, and (10) grasses.—*A. Anderson.*

7902. **BORODIN, D. N. Introduction of cultivated plants into the Union of Soviet Socialist Republics (Russia).** *Proc. Internat. Congress Plant Sciences, Ithaca, N. Y. 1926.* 1: 171-183. 2 maps. Geo. Banta Publishing Co.: Menasha, Wisconsin, 1929.—The earliest introduced plant from America was the sunflower. This was followed by tobacco, potatoes, and corn. Organized plant introduction, however, was not undertaken until after the Russian Revolution. This work is in charge of the Russian Agricultural Agency in America (formerly, Russian Bureau of Applied Botany of the Agricultural Scientific Committee). Up to the present time over 10,000 samples of various seeds and plants have been introduced.—*A. Anderson.*

7903. **BUYZE, D. De aardappelcultuur op "Schoonakker" te pengalengan (Java).** *Landbouw* [*Buitenzorg*] 5(11): 853-886; (English abstract, 887-890.) 1930.—A detailed account is given of methods of potato growing at an altitude of 4,500 ft. including a discussion of green manuring (*Crotalaria usaramoensis*) and disease control. Improvement of the crop by breeding has resulted in 5 new varieties obtained by the author.

7904. **CARVALHO e VASCONCELLOS, JOÃO de. Elementos para o estudo da classificação das aveias.** [Classification of oats.] *Ministeria Agric. Est. Agraria Nac. Nº* 5 Serie A. 1930.—After citing various classifications of cultivated oats by different botanists, the author presents a tentative dichotomous key for the general classification of oats. As the classifications cited do not present all the groups necessary to include certain types of oats cultivated in Portugal, a new group of varieties adjacent to *Avena sativa*, but with well defined characters, which is called *grandiglumis* is created; of which 3 varieties are described. One of these, called *vulgaris*, is the most commonly cultivated oat variety in Portugal. Aside from this, the principal varieties are *Avena byzantina* and, in the north of the country, *Avena strigosa.* —*J. de Carvalho e Vasconcellos.*

7905. **CILLIS, EMANUELE de. I limiti altimetrici della coltivazione dei cereali nel Mezzogiorno d'Italia.** [The altitudinal limits of the culture of cereals in southern Italy.] *Ann. Tecn. Agrar.* [*Roma*] 3(3): 356-365; Latin abstract, 458-459. 1930.—In southern Italy (peninsular and insular) the altitude limits of the culture of the cereals are not geographic but economic. The distribution of species is closely related to the ecological conditions in the coast regions. The influence of temp. increases from the coast to the uplands. The rainfall acts inversely. In comparison to wheat, rye, barley, oats and corn present a greater adaptability to different altitudes. The product per unit of area generally decreases with increasing altitude.—*E. de Cillis.*

7906. **CLARKE, S. E. Pasture investigations on the short grass plains of Saskatchewan and Alberta.** *Sci. Agric.* 10(11): 732-749. 5 fig. 1930.—There has been comparatively little research on pasture management in Canada. Need for conservation of grazing resources, and proper management of range lands, led to the establishment of the Dominion Range Experiment Station at Manyberries, Alberta. Projects under investigation there are: (1) Management of live stock on range, (2) botanical and chemical composition of native vegetation, (3) effects of different grazing practises upon the vegetation cover, (4) improvement and maintenance of range pastures, (5) forage crops for winter feed. After 2 yr. operation of this station, this preliminary report includes a study of the native vegetation of the short grass plains as to, (1) principal species and their palatability, (2) chemical composition of certain of these native pasture plants at different stages of growth, (3) plant succession studied by means of quadrats and transects established on areas representative of varying soil and climatic conditions, also on the pastures which are being subjected to various systems of management, as (a) total protection, (b) continuous summer grazing, (c) deferred and rotational grazing, (d) early spring grazing, (e) late fall grazing, (f) summer grazing with protection during spring months.—*L. Gano.*

7907. **COOK, L. J. Annual report on pasture improvement, Kybybolite, 1928-29.** *Dept. Agric. S. Australia Bull.* 238. p. 58-64. 1930.—Grazing results for 8 yr. are given in tables. The advantages of Subterranean Clover, Wimmera Rye Grass, and top dressing with phosphates are shown.

7908. **CUAYCONG, JOSE. D. I. 52 [sugar cane] outyields Badila and Negros purple at the Hawaiian-Philippine Company [Philippine Islands].** *Sugar News* [*Manila*] 11(1): 16-18. 1 fig. 1930.

7909. **DAVIS, R. L. P. O. J. 2878 [sugar cane] in Porto Rico.** *Sugar Cane* [*Manila*] 10(5): 342-343. 1 fig. 1929.

7911. DODDS, H. H., and P. FOWLIE. Experiments in the harvesting of burned cane. Part III. P. O. J. 213 cane. *S. African Sugar Jour.* 14(6): 407-411. 1930.—Continued investigations gave substantially the same results as those with Uba cane previously reported. Cane burned over to remove the foliage then cut and left in bundles in the field showed by single polarization of the juice a rise in sucrose content more marked than in the case of Uba cane, and maintained it over the first week, after which there was a decline. In the case of cane not burned over there was a decline in sucrose content from the 2nd day about 2½ times as fast as with Uba cane. The purity of the juice of the burned over cane showed no loss for about one week, whereas the juice of burned-over P. O. J. 213 cane decreased in purity about ¾ again as fast as the Uba cane previously reported. Cane burned over and left standing showed a smaller loss of sucrose than the harvested cane whether burned over or not. It showed no appreciable loss in purity for 12 days, after which there was an average daily loss of 1.5% for 10 days. The reducing sugars in general varied inversely with the purity.—*H. B. Cowgill.*

7912. EARLE, F. S. Sugar cane and its culture. 256p. John Wiley & Sons: New York, 1928.

7913. FLAKSBERGER, C. Wechselweizen. *Angewandte Bot.* 11(5): 553-562. 3 fig. 1929.—A group of wheats, designated "Wechselweizen" by Becker and others, has been so named because when sown either in spring or fall they have the capacity to produce a crop. A preliminary planting of 141 wheats in the spring by Flaksberger showed 66 to be true summer, and 75 to be true winter. The 75 winter wheat rows were 50% cut in the fall. The entire rows survived, the cut portions somewhat better due to better aeration in the spring. In another planting of 260 samples from various parts of Europe the true winter types were slightly injured and the true summer badly injured. Dates of heading were the same. At another point 231 samples were fall planted and in this instance all summer wheats, including a durum, came through with success. The plantings from which conclusions are drawn total 25,000, collected from all parts of the world. It was found that no summer wheat fails to survive provided the winters are not too severe. The conclusion is reached that the term "Wechselweizen" applied to a wheat group differing from the true winter and the true summer, is a misnomer as such a group does not exist. Examination of young seedlings of winter and summer sorts showed comparatively very early beginnings of stooling in the former. Half-winter races are recognized in some cases and these are to be looked for as native only in those districts which have been natural centers of dispersal such as Turkestan-Afghanistan-Transcaucasia for *T. vulgare.*—*L. R. Waldron.*

7915. GERHARDT, FISK. Commercial possibilities of the common milkweed. As indicated by its yield and composition. *Indust. & Eng. Chem.* 22(2): 160-163. 3 fig. 1930.—The milkweed plant has been propagated for the first time in sufficient quantities to determine the yield and composition of its various plant parts. Experimental data are presented which indicate a production of 30 bushels of seed, 280 lb. of floss, and 1 ton of air-dry stems per acre. The ratio in yield of pod to seed is approximately 12 to 1, while that of seed to fiber is 2 to 1. The seeds possess large amounts of N, oil, and P. New data are presented relative to their composition: 21% of the seed is composed of a semi-drying oil; 47% of the remaining meal is crude protein. Certain physical and chemical properties of the floss indicate its similarity to kapok. A comparison of its composition with that of several well-known fibers is included. Commercial application indicates that where fiber brittleness is not the determining factor, milkweed floss may be used especially in life-saving, insulating, and playground equipment. New data are presented for the tensile strength of the bast fibers, which approximate 10% of the weight of the stem. Like flax, their application should be found in the textile industry. The stem tissue contains 36.5% alpha-cellulose and compares favorably with many soft-woods in this respect, while its hydration capacity, fiber length, and strength are favorable to the production of a paper pulp of merit.—(*Courtesy Indust. & Eng. Chem.*)

7916. HARDENBURG, E. V., and A. G. V. BOUQUET. The relation of green sprouting to growth and yield of potatoes. *Proc. Ann. Meet. Potato Assoc. Amer.* 16: 73-82. 1930.—Green sprouting resulted in earlier emergence and more rapid gowth in the early growth period. Fewer stems per plant resulted from greening. In greenhouse trials the green weight of the crop was slightly higher from greened seed, as was also the number of larger sized tubers. Tuber-set per stem in the greenhouse was increased by green sprouting, but in the field there was no difference between greened or ungreened seed. The number of stolons per plant was increased by green-sprouting. Greening produced no significant effect on root growth. A period of greening from 4-6 wks. seemingly favored the production of a greater yield of U. S. No. 1 potatoes.

7917. HEIM de BALSAC, F. La fibre de "bontaka" de Madagascar. *Bull. Agence. Gen. Colon* 23(258): 600-616. 2 pl. (1 fold). 1930.—The plant, *Pachypodium rutenbergianum*, of the Apocynaceae, is called in Madagascar "Bontaka" or "Vontaka." While very common in the arid lands of northern Madagascar in the region of Dieto-Suarez, the use of the fiber is limited. Studies have been made in the laboratory on the value of the fiber for textiles and also for paper. The anatomy of the stem and fibers is described and illustrated. The white fibers about 150 cm. long are composed of a mass of ultimate cells isolated from each other and thus differing from flax or jute. The ultimate cells or fiber elements are 3-8 cm. long and 25-50 mm. in diam., some being elliptic. The lumen is small and the walls thick. The tensile and torsion strengths are less than those of the ultimate cells of flax or ramie. The fibers do not have good spinning qualities and are of little value for textile purposes. The plant gives a high yield of cellulose, 56%, but owing to difficulties in preparing and bleaching the material it is not regarded as promising for paper pulp.—*L. H. Dewey.*

7920. HOWARD, ALBERT, and GABRIELLE L. C. HOWARD. The application of science to crop-production. An experiment carried out at the Institute of Plant Industry, Indore. 81p. 12 pl., 7 fig. Oxford Univ. Press: London, 1929. Pr. $3.—This is a discussion of the principles and procedure underlying the founding of the Institute of Plant Industry, Indore, India, supported by various States of Central India and Jajputana, and by private funds. Founded in 1924, under the auspices of the Indian Central Cotton Committee, it is devoted to the problems of the cotton farmer, irrigated and nonirrigated, on the black soils. The fundamental problems are comparison and classification of the species, varieties, and forms of Indian cottons; the effect of soil environment on the cotton root system and on lint; and the relation of environment to fungous and insect pests. Some progress in solving them is recorded. Practical problems include replacing the present low-yielding mixture of species and varieties; 2 different or 1 single variety for the irrigated and non-irrigated areas; controlling competition of perennial grasses; preventing runoff and erosion and providing drainage; relieving colloidal

impermeability of the soil, and increasing the low content of organic matter. Good progress has been made in the improvement of culture. Simple tillage operations control the grasses; leveling and ditching prevent water-logging and erosion, and provide drainage; impermeability and denitrification are relieved by application of safflower and karanj cake or other easily fermentable substances to increase soil acidity; while manuring with all available crop residues, including cotton stalks, first shredded and used for bedding stock and thereafter composted, increases fertility and production, thereby in turn increasing residues. Peanuts are being introduced into the cotton and sorghum (juar) rotation, and making pit silage from sorghum and the growing of alfalfa carry stock through the hot dry season in good condition. The Institute functions also as a training school for agricultural leaders in the supporting States, through endowed scholarships and short courses, and through extension methods in promoting improved farm practices. It also acts as a sales agency for agricultural books, machinery, and seeds. A final chapter discusses the organization of agricultural research. The appendices include a list of 128 papers published on Indian crop production, and a program of cotton investigations.—*C. R. Ball.*

7924. **KRANTZ, F. A.** Relative productivity of certain types of potato seedling populations. *Proc. Ann. Meet. Potato Assoc. Amer.* 16: 56-63. 1930.—200 Irish Cobbler progenies gave a mean yield of 6.45 ± .11 lb. per seedling (total of 5 hills), while the mean of the Cobbler variety was 7.52 ± .12 lb. per group of 5 hills. The difference of the means, 1.07 ± .16 lb. is significant since the deviation is 6.7 times the probable error. It may be concluded that in respect to yield the Cobbler variety presents a genetic combination superior to the average of its progenies. The mean yield 6.87 ± .17 lb. of Triumph seedlings is practically equal to that of the parent, 6.93 ± .10, with a mean difference of only .06 ± .21 lb. per group in favor of the parent, which is not significant. Data presented show a relationship between maturity and yield. The mean yield of the 1st earlies was 4.67 ± .44 lb. per seedling, while that of the 6th earlies was 7.23 ± .27 lb., a mean difference of 2.56 ± .52 lb. per seedling in favor of the late group. Tabulated results on yield of inbred lines from an F_1 seedling of Keeper × Silverskin show that a reduction in yielding capacity occurs during the early generations of selfing. 57 inbred families gave the lowest average yield, 58.0 bu. per acre; the varietal families obtained from Triumph, Cobbler, Early Ohio, and Green Mountain, were intermediate in yield, giving an average yield of 75.5 bu. per acre; and 47 F_1 families gave the highest yield average of 93.2 bu. per acre. It is evident that the F_1 families offer better opportunities for selecting high yielding seedlings than other families.

7925. **KRISHNAMURTHI, RAO K.** Factors influencing the growth and sugar contents of cane. *Agric. Jour. India* 24(2): 91. 1929.—Cane growth starts at a mean temp. of about 68°F. and increases progressively with gradual rise of temp., reaching its maximum at a mean about 88°. Growth is arrested when the mean temp. falls to about 65°, and buds are injured at about 52°. Countries which enjoy a long humid and warm season during the growth period with an average mean temp. of 78° (range 68-88°) and a fairly dry cold season with an average mean temp. of 59° (range 52-65° F.) appear best suited for cane cultivation. Rainfall at the time of ripening affects the sucrose content adversely by inducing shooting. Localities with a heavy and continuous rainfall over a long period without a pronounced ripening season, are unsuitable for the development of sucrose. Saline soils containing much Cl render the cane juices highly saline and also lower the content of sucrose and glucose. NaCl in irrigation water is harmful; the concentration of this salt should be not more than 75 parts in 100,000 of water. Heavy applications of N manures retard the maturation of canes.—*R. K. Krishnamurthi.*

7932. **LORD, L.** The preliminary testing of pure line selections of rice. (Cont) Part III. *Ceylon Jour. Sci. Sect. A. Botany, Ann. Roy. Bot. Gard. Peradeniya* 11(3): 261-267. 1930.—In Parts I and II of this paper the preliminary testing of rice selections in rod-row plots was discussed. Yields of selections grown in rod-row plots were found to be comparable to the yields of the same selections grown in larger plots. In 1927 the mean increase in yield from the inner 3 rows of rod-row plots, replicated 10 times, for selections 1 CPY 15 and 1 CPY 19 over Hinati the control was 26 and 13%, respectively. In 1928 when grown in 1/200-acre plots, replicated 7 times, the increased yields were 27.43 and 9.38%, respectively. The increase in yield of 1 CPY 15 over the control (Hinati) in both years is significant, whereas the increase in yield of 1 CPY 19 is hardly so. For preliminary testing of rice selections rod-row plots can be used to advantage.—*J. W. Jones.*

7934. **LYNCH, D. F. J., and MARSHALL J. GOSS.** Peanut-hull cellulose. *Indus. & Eng. Chem.* 22(8): 903-907. 2 fig. 1930.—An analytical study of peanut hulls to determine their possible commercial use agrees in result with those of other investigators in showing that this waste would be an uneconomical source for pentosans. The comparatively high crude-fiber content would indicate that the hulls might be used as a source for high-grade cellulose. The optimum conditions were determined for the production of cellulose from peanut

hulls by the soda method, the neutral sulphite method, and the sulphate method. Experiments indicate that the best results are obtained with the neutral sulphite method, which gave yields of 40-42% of unbleached pulp. A method is described for producing cellulose from this pulp which analyzes over 90% α-cellulose. There are collected annually at a few points in this country some 70,000 tons of peanut hulls available at a cost of $4-5 a ton, which might serve as a supplemental source for approximately 20,000 tons of α-cellulose.—(*Courtesy Indust. & Eng. Chem.*)

7936. **MANGELSDORF, A. J. Cane breeding in Formosa.** *Hawaiian Planters' Record* 34(1): 11-15. 2 fig. 1930.—Sugar cane breeding at the Shinka Station (near Taiwan, Formosa) as part of the Central Research Institute of Formosa is described. Cross-breeding of sugar cane is mainly carried on in Java where climatic conditions are more favorable, and the crossed tassels when ripe are sent to Formosa for germination and selection. The selection procedure is similar to that practiced in Hawaii. The success of recent releases P. O. J. 105, 161, 36, and more recently 2725, and 2714 has led to great interest in seedling production. Several promising Formosa seedlings F 4 and F 19 are planted to the extent of 7,000 and 9,000 acres respectively. Other seedlings, F 49, 58 and 63 are thought promising. Low labor costs permit general use of the plant cane method which greatly expedites both selection work and the rapid change to a new superior variety, since almost the entire area is replanted each year.—*A. W. Skuderna.*

Gano.*

7939. **MOBERLY, G. S. A mathematical consideration of cane sampling.** *S. African Sugar Jour.* 14(4): 277-279. 1930.—A stalk forms so large a unit in any sample of sugar cane of manageable size taken to determine the sugar content of a field or a smaller parcel, and there are such large variations in size of stalks, that each stalk selected affects the results. The author considers that the minimum requirements of cane sampling are: (1) to take 40 stalks at random from a consignment; (2) halve these and take tops and bottoms of alternate stalks; (3) again halve the chosen halves and take alternate top and bottom quarters of alternate halves.—*H. B. Cowgill.*

7940. **NEIL, BERNIECE, and MARGARET WHITTEMORE. The relation between mealiness in potatoes and the amount of potash in the fertilizer.** *Amer. Potato Jour.* 7(10): 275-283. 1930.—A 4 yr. study was made of the effect of quantity and carrier of K in fertilizers on the mealiness of potatoes when boiled, mashed, baked, or made into chips. It was found that boiled, mashed, or baked potatoes were more mealy when fertilized with a high quantity of K, but the amount of K has little, if any, discernible effect on the quality of chips. When potatoes were treated with equal quantities of K in the form of muriate or sulphate, the value of the 2 forms seems to be equal in producing a mealy potato. The percentage of starch in the potato insofar as this study shows does not seem to affect mealiness. In 1928 and 1929 the more mealy potato contained less starch.—*Authors' summary.*

7941. **NELSON, ALEXANDER. The pasture problem in areas of periodic drought.** *Ann. Appl. Biol.* 17(4): 796-807. 1930.—The paper deals with areas under the Mediterrancan type of climate where periods of moisture supply and low temp. with lowered evaporation alternate annually with periods of low moisture supply and higher temp. with increased evaporation. The suggestions are made that in such areas where no system of economic production has already been evolved, permanent pasture formation for stock production on a system of extensive husbandry would be economic; that permanent pasture could be produced economically by a plant association capable of regenerating itself annually after the drought stress period owing to the production of a large number of seeds by its individual members; that the stock carried by such a pasture during its production period could be carried over the alternating drought period of low or nil production by a self-perpetuating grain crop along the lines adopted in West Australia using the lupin. Various difficulties and amendments of the system proposed are mentioned and discussed.—*Author's summary.*

7943. **NODON, A. Utilisation des fibres de Yucca.** *Rev. Bot. Appl.* 10: 376-380. 1930.—The yuccas are native to America, but are cultivated and acclimated in nearly all tropical countries. The 2 species most widely distributed are *Y. aloifolia* and *Y. gloriosa,* which are arborescent species growing as far north as Cherbourg. Most French colonies have plants of rapid growth containing fibers of excellent quality suitable for numerous industrial applications. Yucca fibers from Isle de Reunion were shown at the expositions in Vienna in 1873 and Paris in 1875, but for lack of efficient methods for preparing the fibers the industry has not been developed. Recent studies have shown that if the leaves of yuccas are treated with weak caustic soda at boiling temp. and further treated with Cl they yield a strong, white, silky fiber. It is suggested that yucca leaves be crushed and the fibrous pulp dried in the colonies, then baled and shipped to France to be treated with chemicals and prepared for spinning. The waste, treated further to reduce it to the ultimate fibers, makes excellent paper pulp.—*L. H. Dewey.*

Soc.* 5(2): 1-123. 1930.—This publication is the first and more general part of a monograph on the wheat of Palestine which will be published in full later. The present article includes a discussion on the yield of wheat per area unit, physical factors affecting growth, crop rotation, and fertilizing problems.

7946. **RINGLEBEN, O., O. VOIGHT, O. UNVERDORBEN, J. GRIMM, und K. SAMMET (bearbeitet von) W. KRÜGER, G. WIMMER, und H. LÜDECKE. Bericht über die fünfjährigen Zuckerrübensortenversuche der Anhaltischen Versuchsstation Benburg.** *Zeitschr. Vereins Deutsch. Zucker-Indust.* 80(Juli): 548-568. 1930.—The results may be summarized as follows: the classification of sugar beets into (a) those with high yields of roots, tops and sugar but relatively low percentage of sugar (b) those with low yields of roots, tops and sugar but with relatively high percentage of sugar is an arbitrary division. Sharp distinctions between the 2 groups cannot be made since the different sorts merge and the differences are not the same each year. High yield and low sugar content or low yield and high sugar content are not always correlated. The leading variety in yield in

every year but one, 1926, had a low sugar content. The variety with the highest average sugar content yielded considerably less than the high yielding variety in every year but one, 1926. However, all the other tested varieties did not show these relative tendencies. The yield and sugar content are much influenced by weather, soil and fertilization. They vary more or less with the different varieties in different years. The cultural practices may also have an influence.—*Authors' summary (transl. by T. E. Odland).*

7948. ROMMEL, GEORGE M. Cellulose resources. II. Cellulose from field crops. *Indust. & Eng. Chem.* 20(6): 587-591. 4 fig. 1928.—Estimated yields of cellulose material which may be expected from American field crops, based mainly on records of agricultural experiment stations covering many years, are given. The average yield of corn stover in Illinois is 2,750 lb. per acre, and in Iowa about the same. Yields of 1,300 lb. dry weight per acre may be expected when corn is harvested from the stalk and 1,900 lb. when it is cured in the shock. The total annual production of corn stover in 9 principal corn-growing States in the Middle West which is available for manufacturing purposes is estimated at 50,000,000 tons, with a dry matter content of fully 33,000,000 tons. The total for the United States is estimated at 62,000,000 tons of bone-dry material, on a basis of 33⅓% moisture content at time of harvesting. The use of cornstalks for industrial purposes may help to offset the effects of the corn borer. Straw from small grains has less potential industrial importance. Sugar-cane bagasse is becoming more valuable as an industrial raw material on account of actual use and the extensive planting of P. O. J. canes.—*G. M. Rommel.*

The use of a lime-magnesium solution for soaking cane points. *Sugar News [Manila]* 10(11): 815-820. 1929.—In tests in Luzon (Philippine Islands) sugar cane cuttings soaked before planting for 24 hr. in a lime-magnesium sulphate solution, yielded considerably higher than controls.

7951. ROXAS, MANUEL L., and NICOLAS D. GRECIA. The influence of spacing on the yields of cane and sugar per hectare under Luzon conditions. *Sugar News [Manila]* 10(11): 826-851. 1929.—A new method of planting sugar cane cuttings consisting of planting the same number of points as in the ordinary method but arranging them in hills of double points twice as far apart in the furrows as in the single point planting, and receiving per hill double the dose of fertilizers, gave substantial increases in yield over the single both in cane and in sugar per ha.—*From authors' summary.*

7952. SCHAFER, E. R., and F. A. SIMMONDS. Physical and chemical characteristics of hemp stalks and of seed flax straw. *Indust. & Eng. Chem.* 21(12): 1241-1244. 3 fig. 1929.—Hemp was found to be practically identical with seed flax in both physical and chemical properties. The possibility of growing hemp for paper manufacture on peat marsh land that has little value for the production of other crops is discussed. It is estimated that fiber may be produced for 7 cents per pound, provided a market exists for at least 1000 tons annually. —(*Courtesy Indust. & Eng. Chem.*)

7953. SCHNEIDER, G., und U. STAFFELD. Ein Beitrag zur Klärung der Getreide-Umpflanzungsfrage. *Deutsch. Landwirtschaft. Presse* 57(19/20): 257-258. 18 fig. 1930.—Transplanting experiments with winter and summer grains were carried out at Berlin-Dahlem and elsewhere to study the influence of planting distance and the age of seedlings on the grain and straw harvest of the transplanted, in comparison with sown, cereals. Planting distances were 33.3, 25, 20, 16.7 and 14.3, cm. apart, each way. Plants were distributed therefore 9, 16, 25, 36 and 49 per m^2, respectively. The more widely spaced transplanted plants gave a lower grain yield for winter rye and winter wheat than was secured from ordinary seeding; only with the narrow planting did the 2 yields become equal. With spring-sown grains all spaced transplantings showed lower yields than that given by the seedings. The higher grain yields have been obtained from the larger plant and culm number per unit area and with poorer stooling and lower yield per plant. The lower grain yields, on the other hand, have been secured from smaller plant and culm number per unit area and with strong stooling and high yield per individual plant. In future studies of cereal transplanting, consideration must be given to the fact that the method is not suitable to all regions, soils or varieties, but only under special climatic and soil conditions will transplanting be of value. Cereal varieties that stool strongly and have the capacity to produce high percentages of fertile culms will naturally have especial value, combined with favorable growth conditions perhaps not at present known.—*G. Schneider (transl. by L. R. Waldron).*

7954. SETHI, R. L. Root development in rice under different conditions of growth. *Mem. Dept. Agric. India. Bot. Ser.* 18(2): 57-80. 3 pl. 1 fig. 1930.—The root development of rice was studied in earthen pots, wooden boxes, and under field conditions. Plants were grown in pots containing gravel, sand, loam, clay, and a mixture of loam and clay. Certain pots containing loam were fertilized. In the field, rice was grown with different fertilizer treatments and different conditions of cultivation. 2 early- and 2 late-maturing rices were used in the experiments. The root systems were studied at intervals from 2 weeks after planting until maturity. 2 distinct types of roots were observed: (1) long, thin, flaccid, light brown roots with many branches; and (2) bold white comparatively short, almost unbranched roots. Root development was directly proportional to the amount of available nitrogenous plant food and soil moisture. At heading time the bold white roots, which previously had increased as the growing season advanced, were no longer present and the whole root system became weak and flaccid. The absorption of plant food is largely completed when the plants reach the flowering stage. Late varieties had better root development than early maturing varieties. Coarse grained varieties had coarser roots than fine grained varieties. Roots in pots containing clay were bright red, in pots containing loam fertilized with ammonium sulphate they were dull red, and under other conditions dull white or white. The average range in root penetration in pots was 2-4 ft. Most of the root system was found in the surface 1-2 ft. Roots penetrated deeper in pots than under field conditions. In most cases root development was proportional to shoot development. In soils fertilized with nitrogenous material the root system was nearer the surface than in unfertilized land. A better root system developed on plowed than on unplowed land. An anatomical study of rice roots showed that the old white roots resembled those of wheat, whereas the old flaccid roots are quite similar to those of the water hyacinth (*Eichornia crassipes*).—*J. W. Jones.*

7955. SMITH, D. C., and E. N. BRESSMAN. Some effects of seed treatment on the germination and subsequent growth of wheat. *Jour. Agric. Res.* 40(1): 25-36. 3 fig. 1930.—The effects of solutions of potassium thiocyanate, ammonium thiocyanate, trichloroethylene, ethylene chlorhydrin, ethylene chloride, ethyl bromide, and carbon disulphide, on 16 varieties of common wheat were studied. Chemical treatments were also combined with freezing. None of the treatments stimulated germination or the growth of plants subsequently produced. Ammonium thiocyanate was decidedly toxic. Ethyl bromide was slightly toxic. Pure water treatment

caused a stimulation which lasted until maturity.—*D. C. Smith.*

7956. SPENCE, H. L., Jr. Puncture vine, a new pest in Idaho. *Idaho Agric. Exp. Sta. Circ.* 60. 4p. 1 fig. 1930.—*Tribulus terrestris* is described, and control methods are outlined.—*H. M. Steece (courtesy Exp. Sta. Rec.).*

7957. STAHL, CHR. Forsøg med Opbevaring af Rødkløverfrø. *Nordisk Jordbrugsforsk.* [Copenhagen] Heft 4. 313-326. 1930.—Periodical germination tests of Red-clover seed samples stored under different conditions showed that the seed maintained germinating capacity better when stored in a dry, heated, laboratory than when stored by commercial seedsmen. In the laboratory the average germination, including hard seeds, was reduced during 2 yr. from 95% to 74%. In commercial samples the average germination during the same time was reduced to 44%. The result emphasizes the importance of dry storage. In the laboratory the average hard seed content increased during early storage from 4% to 10%, later remaining constant. As stored commercially the hard seed content did not increase, remaining low during the whole period. Seed which, after 2 yr. in commercial storage, showed a laboratory germination of 10-60%, germinated only 1-10% in the field under favorable conditions.—*C. Stahl.*

7958. STAPLEDON, R. G., and WILLIAM DAVIES. Experiments to test the yield and other properties of various species and strains of herbage plants under different methods of management. *Univ. Coll. Wales, Ser. H. No. 10.* 41p. 1930.—Continuing investigations to compare sustained yields, tillering, persistency, and leafiness, 210 1/400th acre plots, previously dressed with basic slag, were seeded, May 29, 1923, to 22 species and strains and 2 mixtures of grasses and clovers. During the following 4-5 yr., data were secured from these plots managed for pasture, hay, and sheep grazing. 13 weeks after seeding, commercial strains (except meadow foxtail, the seed of the tested indigenous strain being larger, heavier and more readily established) showed greater rapidity of development. Italian rye-grass alone and the hay mixture containing it, ranked first in produce. For 4 harvest yrs., 5 indigenous strains (perennial rye-grass, cocksfoot, timothy, tall fescue, meadow foxtail) yielded highest in pasture, for total and for leaf produce. The pasture mixture averaged higher than the hay mixture for total yield and for leaf yield. Indigenous timothy ranked 5th in whole yield and 4th in leaf yield. Rough-stalked meadow grass gave lowest yield. Montgomery red clover outyielded the 4 other clovers tested. "Top" grasses (such as perennial rye-grass, Italian rye-grass, cocksfoot, timothy, meadow fescue, tall oatgrass, meadow foxtail) outyielded "bottom" grasses (sweet vernal, crested dogstail, rough-stalked meadow, fine-leaved fescue) in total and in leaf produce. Weather and age of sward affect the results, but a progressive diminution of yield was generally noted, in part due to repeated defoliation and lack of fertilizer. Continued cutting tended to leafiness, compensating the loss in total yield by an increase in more nutritive leaf produce. Although the bulk of produce for all species tested was made in May and June, the indigenous strains showed a different seasonal persistency, with prolonged production and winter greenness. Clovers showed shorter growing season, little to no winter growth, but later (summer) production. A lenient system of cutting (pasturing), begun late (May 28th), with 4 cuts per season, gave more even production for 6 species tested, the September 10th yield averaging highest. In tiller production, indigenous strains (except perennial rye-grass) averaged higher,—rough-stalked meadow grass and fine-leaved fescue outranking, with indigenous timothy most persistent in tillering, this characteristic being useful in establishment and maintenance of weedless pastures. In palatability, timothy rates high. Maximum tillering for most species occurred in May and June, falling progressively under drastic cutting. Commercial strains of timothy rank high in stem production, thus making it a typical hay grass. In stem shoots, commercial strains of 6 grasses excelled, sweet vernal grass (a "sternny" hay) being highest, followed by Italian rye-grass, perennial rye-grass, commercial tall oat grass and commercial timothy. The hay yield also diminished progressively, in total bulk during the 4 harvest years, but the percentage due to aftermath generally increased. Indigenous and commercial timothy gave highest yields of aftermath in 1924, falling in total yield for 4 harvests to 2nd place. Indigenous tall fescue gave highest yield of any grass for aftermath and for pasture leafiness, but is not relished by sheep, though eaten by horses and cattle, nor is it easily established. In yield of aftermath the 2 mixtures averaged highest, and the 5 indigenous grasses averaged higher than their commercial strains in hay, pasture, and leaf yields.—*L. Gano.*

7959. TAMM, ERNST, und KARL GOEPP. Ueber den Einfluss von Saatzeit, Saatmenge und Saatpflege auf den Ertrag von Winterroggen bei verschiedener Stickstoffdüngung. *Landw. Jahrb.* [Berlin] 72(2): 293-334. 1930.—In experiments performed at the Berlin-Dahlem Experiment Station the best dates of seeding winter rye were September 25 to October 5. Yields decreased with delay in date of seeding. The date of emergence of seedlings stood in closer relationship to yield and development of the plants than the date of seeding. Nitrogen fertilization in fall gave no extra returns. The best rate of seeding was 80 kgm. per ha.; low rates of seedings gave good returns with very high applications of nitrogenous fertilizers. Special care of seed grain did not materially increase yields.—*K. Goepp (transl. by K. H. Klages).*

7960. VAVILOV, N. I. Geographische Genzentren unserer Kulturpflanzen, *Zeitschr. Indukt. Abstamm.- u. Vererb. Suppl.* 1: 342-369. 6 fig. 1928.—The great diversity of local races of Linnean species in certain regions led to a search for the centers of genesis or original home of a series of species. The center of morphogenesis of a Linnean species is identified as the central point of diversity of its races and plant characters. Numerous expeditions were sent into all parts of U. S. S. R. and many parts of the world to study plant diversity and to collect specimens. Determinations of centers of maximum density were arrived at through consideration of strict identity of the Linnean species, the region where the species was found, the racial composition of the species, distribution of heritable diversity and increase of diversity, including a similar study of other closely related cultivated and wild species and varieties. On these grounds the author considers that wheat has 2 centers of origin. The 42 chromosome "weak" wheats show their greatest diversity in southwest Asia, in southeastern and northern Afghanistan, about the foot of the Himalaya mountains, and in neighboring districts of India. The 28 chromosome "hard" wheats show their maximum diversity in the mountainous regions of East Africa in Abyssinia. Einkorn is concentrated principally in Asia Minor, and in southern Syria. Bearded barley is most highly diversified in Abyssinia and naked barley in southeastern Asia. Rye and oats probably originated from weed-like plants infesting the older or so-called primary cereals. The greatest racial concentration of rye occurs in Transcaucasia and eastern Asia Minor. A wealth of forms of cultivated oats was found in the areas of emmer culture in Spain, Bulgaria, Abyssinia, and elsewhere. With extension of emmer culture northward into moister regions, oats invaded the earlier cultures and became an independent crop. 5 principal centers of origin were recognized for a series of plants which includes most of our cultivated crops. These centers are the mountainous regions of southwest Asia, of southeast Asia, of the coastal regions of the Mediterranean and of the Spanish Peninsula, of northeastern Africa, and, in the New World, of Mexico and Central America, and Colombia and Peru in South America. Mountainous regions with their great variety of soil and climate provide the most favorable conditions for the genesis of plants. The whole process of geographical

evolution consists in the falling away of dominant characters. At the borders of the geographical extension of isolated cultivated plants, principally recessive forms were observed.—*V. H. Florell.*

7961. VIVARELLI, LUIGI, e CARLO BERTO CERONI. Campo di orientamento per razze di grano geneticamente migliorate. [Trial plots for varieties of grain genetically improved.] *Italia Agric.* 67(8): 3-13. 1930.—The authors experimented with 28 varieties of wheat in an attempt to show relationships between certain cultural practices and resulting morphological differences. They are not ready, without much more extensive data, to give any practical advice on the most suitable variety for cultivation. Tables showing their results are given.—*H. D. Hill.*

7962. VIVENZA, A. La coltivazione della Soja in Italia e nelle Colonie. [Cultivation of soy bean in Italy and her colonies.] *Atti Soc. Ital. Prog. Sci.* 1927: 375-393. 1928.—In Italy the soy bean cannot be grown as a 2nd crop following a cereal, but only as a principal crop, partially replacing maize, beets or beans. Irrigation is needed for best results in the arid conditions of southern Italy. The first crop of soy beans lacked root tubercles but these gradually appeared with successive crops. Little difference could be seen in the development of plants with and without the tubercles. The early varieties of soy bean are the only ones which can be grown in Italy, and the yield of these is rather low, 5-20 bu. per acre, depending on soil fertility. While the culture of the soy bean in Italy may sometimes be usefully substituted for that of maize or beans, no great hopes should be built on it. Hitherto very few experiments have been made of soybean cultivation in the Italian colonies. The indications are that it would succeed in Somaliland and on the Eritrean plateau. This is less probable for Libya, where the irrigated zone is limited and occupied by other more remunerative crops.—*A. Vivenza (transl. by H. S. Wolfe).*

7963. WASSING, A. Formation of water shoots and their influence on the yield of P. O. J. 2878. *Sugar News [Manila]* 10(6): 394-397. 1 fig. 1929. Reprinted from *Arch. Suikerindust-Nederland. Indie* 1(2): 54. 1929.—Only a very small part of the water shoots formed in a field of P. O. J. 2878 appear prior to harvesting. In practice only shoots having a length of 2.5 m. should be harvested. The formation of water shoots probably has a harmful influence on yield. It is advisable to prevent as much as possible the formation of water shoots.—*Author's summary.*

7964. WERNER, H. O. Some facts concerning the productivity of irrigated seed potatoes. *Proc. Ann. Meet. Potato Assoc. Amer.* 16: 120-131. 1930.—When spindle-tuber was present in seed stocks, irrigated seed potatoes degenerated as to productivity and quality of tubers much more rapidly than did dry land grown stocks. This deterioration of the irrigated seed stock increased progressively. Variation in the amount of irrigation water, or in the manner of applying it, did not alter the detrimental effect. With healthy seed stocks, or those free from spindle-tuber, irrigated and dry land grown seed potatoes were apparently of equal value wherever they were tested.—*Author's summary.*

7965. WHITE, J. W. Comparative returns in feed units from crop rotation and pasture. *Jour. Amer. Soc. Agron.* 21(6): 589-593. 1929.—A rotation of corn, oats, wheat and hay is compared with pasture, largely Kentucky blue grass with some red top and sweet clover, on 3 Pennsylvania soils with 4 fertilizer treatments. As a general average, pasture produced 10.9% more air-dry matter, 7.4% more digestible nutrients, and 189% more digestible crude protein than rotation. Manures increased nutrients as follows: K 29% and 43%, N 37% and 6%, respectively, on pasture and rotation. PKN exceeded reinforced manure (MP) 9% on pasture but MP was 9% more effective on rotation. Acre labor costs were, rotation $59.61, pasture $2.80. Rotation produced 799 lb. digestible crude protein and 10,096 lb. total digestible nutrients compared with 1986 and 8535 lb. respectively on pasture. Labor cost of one ton of digestible protein was $178.00 on rotation and $2.82 on pasture.—*A. C. Maxson.*

7966. WOODMAN, H. E. Pasture research. Recent pasture research in Great Britain. *Trop. Agric. [Trinidad]* 6(12): 331-336. 1929.—Results obtained at the School of Agriculture, Cambridge, show that frequently-mown pasture grass is easily digestible and highly nutritive. Roughly ¼ of the dry weight consists of proteins, a proportion maintained practically throughout the year. This proportion is about 2½ times as great as that found in hay, and there is also much less fiber. Under conditions of close cutting or heavy grazing, there is little difference in nutritive value between different species. Cuttings of young grass, steam-dried and compressed into cakes, can replace oil cakes in rations for dairy cows and fattening cattle. Drying does not impair digestibility. The protein content of the dried cuttings of grass mown at 1-, 2-, and 3-week intervals averaged 25, 23.5, and 21% respectively. Though the protein content falls off with the longer intervals, there is no loss of digestibility. Grass cut at 2-week intervals resists drought conditions better than that cut at 1-week periods. As animals grazing young flushes of herbage will be receiving an excess of protein, they should be given a supplementary ration of some carbohydrate-rich food.—*R. E. Hunter.*

7967. ANONYMOUS. Sugar beet experiments, 1927. *Ireland Dept. Agric. Jour.* 28(1): 37-66. 1929.—Of the 4 varieties of sugar beet included in the trials conducted during the 3 seasons, the Dutch (Kuhn & Co. P) and the German (Klein Wanzleben Original Z) varieties were superior both in yield and sugar content to the Danish (Scandinavian Seed Co.'s K 7866) and the French (Vilmorin's Improved Selection B) varieties. While the yield and sugar content of the Dutch and German varieties were practically identical, the Dutch variety was distinctly superior to the German variety as regards the tendency to bolt, and it is preferable for cultivation in Ireland. A top-dressing of nitrate of soda at the rate of 1 cwt. per acre, applied after the crop was singled, did not lower appreciably the sugar content of the beet. The increased yield resulting from this top-dressing depended largely on the condition of the soil and the growth of the crop at the time it was applied. Under favorable conditions of soil and growth, the top-dressing did not materially increase the yield, but in unfavorable seasons, or when the crop was attacked by pests or diseases, the top-dressing was the means of carrying the plants over a critical period. Top dressings of nitrate of soda in excess of 1 cwt. per acre slightly depressed the sugar content of the beet without producing any compensating increase in yield.—*Author's summary.*

7968. ANONYMOUS. An experiment in cane planting, using different amounts of seed cane per acre. *S. African Sugar Jour.* 14(5): 353-355. 1930.—In a single season's test 1/15 acre plots with rows 5 ft. apart were planted in quadruplicate (1) with a single row of stalks in each furrow, (2) with 2 rows of stalks in each furrow, and (3) with half the number of stalks needed for a single row spaced equally distant apart. Single-row planting and double row planting gave increased average yields of stalks over planting with the stalks spaced equally in the furrow. Double-row planting gave a slight increase over single-row planting, but not sufficient to compensate for the increase in quantity of seed cane used. Chemical analyses of the stalks from the various plots gave results of no significance.—*H. B. Cowgill.*

7969. **BARSS, ALDEN F.** Effect of moisture supply on development of Pyrus communis. *Bot. Gaz.* 90(2): 151-176. 11 fig. 1930.—An experiment was undertaken to determine the effect of varying amounts of water upon both the gross and the microscopical development of *P. communis*. 48 dwarf pear trees were divided into 4 lots which were treated uniformly except for watering. Flower clusters were more abundant on trees given more than the minimum amount of water. The number of flowers to each cluster averaged less when abundant water was supplied, due to the high percentage of axillary clusters produced. Abscission of blossoms and partly developed fruits was more pronounced where least water was available. The number of fruits matured by a tree in any one season appeared to have a greater effect on the size of the individual fruits and on the crop produced the following year than did the actual amount of water applied to that tree. With a small crop moderate watering was associated with production of full-sized, normal fruit. With a large crop, moderate watering was associated with production of much smaller and a poorer quality of fruit than when abundant water was applied. A pronounced shortage of water resulted in small fruits of poor flavor and quality. The value of thinning to secure increased size in case of water shortage is emphasized. There appeared to be a close qualitative and quantitative relationship between shoot growth and fruit development, regardless of the amount of water that a tree received. A large fruit crop seemed to make less demand on the water supply than did large shoot growth. The most pronounced difference in gross topography of the tissues is in the extent of the xylem area. As between a large, medium, and small amount of water, this stands in the proportion of 15 to 2 to 1 respectively. The cortex is largest in the moderately watered lot. A comparison of cells showed a number of definite differences in the cortex, phloem, and xylem cells in the different lots, especially as to number and size. The pith cells seemed practically identical in all lots, regardless of the amount of water applied. A great development of xylem may accompany increased water supply to pear trees in rich soil without resulting in succulence, but in a greatly increased volume of firm, sound wood. An attempted interpretation of the results secured suggests that, following changes in the water supply, alteration in the metabolic processes may be due to physical or nutritional causes or both.—*From author's summary.*

7970. **BECKWITH, CHARLES S.** Experimental work with cranberries in New Jersey. *Wisconsin State Cranberry Growers' Assoc.* 43: 17-23. 1929.—Data are presented showing the increases due to applications of plant nutrients on plots of savannah cranberry land in New Jersey for 10 yr. They indicate that on one acre 500 lb. of a mixture containing 75 lb. nitrate of soda, 75 lb. dried blood, 300 lb. rock phosphate and 50 lb. sulphate of potash can be used with profit. On other types of land the advantage is not assured. Further, the use of fertilizer is warranted only if increased vine growth is the factor required for the desired crop increase. The blunt-nosed leaf hopper, which transmits the virus of the false blossom disease, can be controlled in New Jersey by submerging the bogs between June 10 and 20.—*C. S. Beckwith.*

7971. **BERGMAN, H. F.** Respiration of cranberry plants in relation to water injury. *Proc. 60th Ann. Meet. Amer. Cranberry Growers' Assoc.* 21-25. Jan. 1930.—The injury to temporarily submerged plants is due to lack of O and not to poisonous substances in the water. O is available to the plants in water solution. The amount of O is limited by the temp. of the water and the amount of organic matter present that is undergoing decomposition. The plant's need for O increases with temp. and also with the growth rate of the particular part of the plant involved. The amount of O in water is increased during clear weather by photosynthesis.—*C. S. Beckwith.*

7972. **BREMER, A. H.** Sorts- og stammekontrollen av rot- og grønsakvokstrar. [Variety and strain control in root and truck crops.] *Selskapet Havedyrkningens Venners Medlemsskr.* 8(3): 70-78. 1930.—Laboratory testing of variety and strain in root and truck crops is not sufficiently exact with present available means. Many important characteristics do not appear until the plant has been grown a shorter or longer time with light. Imported seed should be tested by growing samples under electric light in the winter. For crops of which local strains and seed production exist, especially if the distinguishing characters are physiological, field plot testing is required. The Norwegian system with comparative strain trials and official support of elite stock seed production should be supplemented with control of the production and sale of the commercial seed.—*A. H. Bremer.*

7973. **BRYDEN, J. D.** Development in oranges. A study of the influencing factors. *Agric. Gazette N. S. Wales* 41(12): 919-928. 1930.—A correlation exists between soil moisture content and rate of development of orange fruits. The amount of moisture available to the tree is the most important factor influencing fruit size, although manurial treatment cannot be entirely disregarded as a factor. The more stable size of oranges grown under irrigation is due to the maintenance of an even soil moisture content. A relationship exists between the rates of development of oranges borne on the inside and those on the outside of Washington and Valencia trees. Deficient moisture during the period of development, especially if high temp. prevails, retards the rate of growth. Lack of available moisture causes a greater check during early development than when the fruits are more nearly mature. Oranges quickly recover from a check in growth where it is caused by a variation in the soil moisture content. The size of inner foliage fruits as compared with those borne on the surface foliage is controlled to a great extent by climatic conditions and water available immediately after setting.—*From author's summary.*

7974. **CECCARELLI, GIUSEPPE.** Manuale del viticultore moderno. Vol. I. La pratica della viticultura a base d'innesto. 236p. Vol. II. La teoria della viticultura a base d'innesto. 294p. Francesco Battiato: Catania, 1929.

7975. **CHACE, E. M., C. G. CHURCH, and D. G. SORBER.** Large-scale experiments in sulfuring apricots. *Indust. & Eng. Chem.* 22(12): 1317-1320. 2 fig. 1930.—The commercial process used for sulphuring apricots in California is described. Experiments were carried out in sulphuring fruit with liquid SO_2 in thermally controlled boxes. Under the conditions of the experiments, the appearance of dried fruit, with few exceptions, seems to be correlated with its SO_2 content. The concentration of SO_2 in the atmosphere in which the fruit is treated is a prime factor in controlling the amount of the gas retained. The length of the sulphuring period is also an important factor, although about 50% of the gas retained is fixed during the first half hour of treatment. Temp. is not important, but high temp. gives the product a reddish or cooked appearance. Fruit of good appearance and good keeping quality was obtained with 3% SO_2 in 2 hours at 100-110° F.—*E. M. Chace.*

7976. **CLAYTON, E. E.** Increasing stands from vegetable seeds by seed treatment. *New York State Agric.*

Exp. Sta. [*Geneva*] *Bull.* 554. 16p., 2 pl. 1928.—Supposedly healthy seed of cabbage, lettuce, radish, spinach, pea, corn, cucumber, tomato, and string bean were treated with organic mercury preparations, including Semesan, Uspulun, and Bayer Dipdust. Semesan was used both as a liquid and as a dust. Treated and untreated seed were sown at intervals from early spring to midsummer and records taken of germination period, percentage germination, and, in some cases, yield. With seed sown very early in the year the germination periods were long and the percentages of germination for untreated seed were low, owing chiefly to the decay of many seeds, some before sprouting and some very soon afterward. Seed treatment with the organic mercury preparations gave considerable protection against this decay and thereby increased the stands. With seed sown later, after the soil had become warm, the germination periods were shorter and the percentages of germination secured with untreated seed were much higher. Decay of seed was not a serious problem and seed treatment with the organic mercury preparations proved of little benefit. The yields recorded in a limited number of cases indicate increases somewhat greater than would be expected from the gains in germination only. Vegetable growers can very profitably treat seed that is to be sown early, while with midsummer sowings there is less need for this protection. In greenhouse tests seed treatment greatly increased stands from seeds sown in midwinter, during which period seed and seedling decay is a serious problem. Comparative sowings of similar lots of seed treated or untreated late in spring, however, showed little benefit from seed treatment.—*Author's summary.*

7977. **GEISE, F. W. Fertilizer studies and the production of sweet potatoes.** *Maryland Agric. Exp. Sta. Bull.* 311. 38p. 9 fig. 1929.—Fertilizer experiments conducted on sweet potato farms on both the eastern and western shores of Chesapeake Bay showed large increases in yield of sweet potatoes from potash and relatively small increases from phosphoric acid and nitrogen fertilizers. Lime was beneficial in one test on strongly acid soil. Cultural practices are expounded and variety descriptions given.—*J. Bushnell.*

7978. **GIRARDI, GIULIO. La peonia, varietà e coltivazione.** 57p. 7 fig. Francesco Battiato: Catania, 1929.—This popular monograph of the peony group discusses: (1) The variety indigenous to Europe, with *Peonia officinale* as its type, is described. Brief accounts, with 4 figures, of other varieties from Siberia, Portugal, and the Caucasus are given also. (2) The herbaceous, double-flowered peony from China is described and its cultivation and propagation is presented in considerable detail as it is the most important garden peony. 297 named varieties with single flowers and 41 named varieties with single flowers but with stamens transformed into petal-like growths are described. (3) Of the woody or shrubby type from China or Japan, 102 garden varieties with double flowers and 66 varieties of the Japanese peony with single flowers, as well as the cultivation and propagation of this woody type, are described briefly.—*B. F. Lutman.*

7979. **GRÉZAUD, FERDINAND, (avant-propos par LOUIS SOURSAC). Culture potagère.** 89p., 22 fig. (4 col.) L'Indépendant: Perpignan, France, 1928.—A handbook of vegetable culture, based on practices in southern France, containing general information on materials, tools, and equipment, detailed directions for growing most of the common vegetables, descriptions of varieties, tables of longevity of seed, numbers of seed in unit weights or volumes, temp. requirements of plants, etc., and a garden calendar by months.—*W. B. Mack.*

7980. **HINTON, J. C., and T. SWARBRICK. The shape and quality of apples in relation to their position in the fruit cluster. Progress report.** *Ann. Rept. Agric. & Hort. Res. Sta. Univ. Bristol* 1929: 67-72. 1 pl. [1930].—A large number of fruits on selected trees of the variety Allington Pippin were tagged just after the "June drop." Information was recorded concerning the type of wood which bore the fruit bud, the number of fruits carried by each cluster to the June drop, the rate of growth, the leaf area and amount of shade near each fruit, and the behavior of each apple in storage at room temp. This preliminary paper reports only the effect of the position in the flower cluster on the shape. Fruits from the terminal flowers of the clusters were oblong and, in some, the cavity was filled with flesh which extended part way down the stem, giving a "beaked" appearance. Fruits from lateral flowers were round to oblate, with normal cavities. Fruits from terminal flowers seemed to have more acid and retained more crispness and juiciness, when kept until December 20 at room temp., than fruits from lateral flowers, but they were not nearly so sweet or aromatic.—*W. H. Chandler.*

7981. **HORNER, JOHN M. A study of the composition of pineapple plants at various stages of growth as influenced by different types of fertilization.** *Univ. Hawaii Exp. Sta. Assoc. Hawaiian Pineapple Canners Bull.* 13. 1-34. 8 pl. 1930.—The growth rate on all plots was much the same, the plots receiving potash being slightly superior. The dry weight of green pineapple plants is approximately 17% of the green weight. Ash constitutes about 7% of the dry weight. Potash is the most abundant ash constituent, being approximately 37% of the total ash in the leaves, 32% in the stem, and 45% in the fruit. The ratio between total sugars and reducing sugars is nearly constant at all ages and the total amount seems to be correlated with the age of the plant. The total sugar content rises to a high peak as the fruit ripens. The ripe fruit contains approximately 10.5% total sugars and 6.8% reducing sugars. The ripe fruit contains about 87% water. The starch content of the pineapple plant is very variable. The pineapple plant has a fairly constant ratio between nitrogen and lime. Although influenced somewhat by soil and cultural conditions, the plants for any one general region have essentially the same ratio. Nitrogen fertilizers produce a good growth in the pineapple plant but this improvement is only apparent for about 6 months after the application. Phosphoric acid if applied within the limits of the basic requirements of the plant, i.e., 125-150 lb. per acre, may increase fruit size. The plants remove more potassium from the soil than any other constituent, taking an average of about 1456 lb. per acre of K_2O as against 111 lb. of P_2O_5 and 491 lb. of N. Fertilization practices supply far less than the amount removed by the plant.—*From author's summary.*

7982. **HOWES, F. N. Observations on bananas in Siam.** *Jour. Siam Soc., Nat. Hist. Suppl.* 8(1): 41-48. 1929.—In an attempt to find in south-eastern Asia, particularly in the Indo-Malayan region (presumably the original home of the banana), a variety suitable for the West Indies and resistant to the Panama disease (*Fusarium cubense*), the author traversed southern Siam. The Siamese varieties of seeded and seedless bananas found are described.

7983. **HOWLETT, FREEMAN S. Further experiments on the relative self-fruitfulness of apple varieties.** *Proc. Amer. Soc. Hort. Sci.* 26: 49-55. 1929 (1930).—The results of self and cross pollination experiments with the varieties Baldwin, Delicious, Gallia Beauty, Grimes, Jonathan, McIntosh, Rome Beauty, Stayman Winesap, Wealthy and Yellow Transparent in 1928 and 1929, and a summary of work on all varieties from 1924 to 1929 inclusive, are given. The method employed in 1928 and 1929 was the enclosure of limbs in cheesecloth bags. The conclusions are: (1) all varieties selfed failed to produce degrees of self fruitfulness equivalent to full commercial yields; (2) these varieties differed in their degree of self-fruitfulness. Those of the lowest degree were McIntosh, Rhode Island Greening, Stayman and Delicious. In an intermediate group were Jonathan, Grimes, Oldenburg, Wealthy, Baldwin and Yellow Transparent. Those of the highest degree were Rome Beauty and Gallia Beauty.—*F. S. Howlett.*

7984. **KAKIZAKI, YÔITI. A physiological interpretation of self-incompatibility in the common cabbage.** (In Japanese.) *Japanese Jour. Genetics* 5: 121-123. 1930.

—Self- and cross-incompatibility in cabbage are due to the slow rate of pollen-tube growth. Pseudofertility in bud-pollination, which is very conspicuous in this plant, is mainly due to insufficient action of the style to inhibit the pollen-tube growth, and, in addition, to the longer time duration for the growth of pollen tubes and the shorter distance to be traversed.—*Y. Kakizaki.*

7986. **LONGLEY, L. E. Influence of various propagating media on the rooting of cuttings and layers.** *Proc. Ann. Meet. Amer. Plant Propagators Assoc.* 1930: 37-44. 1 fig. 1930.—4 types of peat of varying acidity and structure and 3 sands of varying fineness and acidity were used as propagating media, as well as various combinations. The data indicate that the acidity of the medium has some influence in promoting rooting, but this relation is not constant. However the acid sands usually showed uniformly good rooting results. An American peat of high acidity showed nearly as good results as a foreign peat of the same acidity and similar structure. There was a definite relation between prevalence of "damping off" fungi and the acidity of the media. In general the more acid media tended to decrease damping off, but with a few plants the reverse is true.—*L. E. Longley.*

7987. **LUNDEGÅRDH, H. Drivning av gurkor och jordgubbar med kolsyrebegasning.** [Effect of CO_2 fertilization on cucumbers and strawberries.] *Meddel. Centralanst. Försöksväs. Jordbruksområdet* [*Stockholm*] 384. 1-15. 10 fig. 1930.—Denatured alcohol was burned in simple open lamps, producing almost exclusively CO_2 and H_2O, in specially arranged glass houses. The 2 experiments on cucumbers were carried on with 4 parallels. CO_2 fertilization increased the number of the fruits as well as their weight. The increase in yield was 28.5-45%. The CO_2 content of the air was maintained at 3-4 times the normal. CO_2 fertilization also caused strawberries to ripen earlier than usual, and the number of fruits was increased 12%, although the weight was not influenced to the same extent.—*From author's summary* (*transl.*).

7988. **McDONALD, J. H. Coffee growing: with special reference to East Africa.** xx+205p. Illus. East Africa: 91 Great Titchfield St., London, 1930.

7989. **MANARESI, ANGELO. Contributo allo studio dei semenzai e dei vivai di gelso (Morus alba L.) dell'Emilia e della Romagna.** [Seeding and growing mulberry.] *Ann. Tecnica Agraria* [*Rome*] 3(2): 173-189 1930.—This is a study of nursery practice with the white mulberry in Italy. Seed is planted in June or July from fresh fruit, or in the next spring, using 2-18 gm. of seed per sq. m. Under favorable conditions 10-20% of the seedlings may be grafted the spring after planting, but frequently the seedlings are left in the seed-bed 18-20 months, or are transplanted into the nursery row, 21 × 33 cm. apart. The plants are thinned the winter after transplanting, and are grafted in the autumn with dormant buds, or in the spring with whip-grafts or with active buds. In the following winter the trees are further thinned and are first pruned for shaping. Shoots from whip-grafts will be 1.59-3.54 m. high in a year from grafting. Shoot development is progressively less from grafts by dormant buds, active buds and crown grafting. Sometimes it is possible to graft transplanted seedlings the same spring, saving a year.—*A. Manaresi* (*transl. by H. S. Wolfe*).

7990. **NAGAI, KEIZO, and IKURO TAKAHASHI. The "root-grafting" of citrus trees.** *Proc. Third Pan-Pacific Sci. Congress, Tokyo* 2: 2014-2022. 1926 (1928).—The so-called "root-grafting" (Netsugi in Japanese) described is a special method of inarching which has apparently been in practice for at least 50 yr. in parts of Japan. It has been developed into a practical method at the Imperial Horticultural Experiment Station, Okitsu. Weakened trees can be strengthened, those grafted on unfit stocks freed from defects, and senile trees rejuvenated. Yuzu orange trees make the best stocks for root-grafting. The root-grafting can be done in any season, except late fall and winter; the best season is late March and April. Thomson navel orange trees grafted on trifoliate stocks are very weak, but their vigor and fruitfulness can be decidedly improved by root-grafting. The experiments on root-grafting with stocks of several varieties of declining Thomson navel orange trees worked on trifoliate stocks show that those inarched with the Yuzu orange gave the best results, the trees growing steadily, the crop being large and the quality excellent; those inarched with the sweet orange were second best but were susceptible to disease; those inarched with the sour orange and Japanese summer orange were vigorous but gave a small crop and the quality was poor.—*From author's English summary.*

7991. **NEBEL, B. R. A thumb test for distinguishing Mazzard (Prunus avium L.) and Mahaleb (Prunus Mahaleb L.) root-stocks.** *Amer. Naturalist* 65(696): 95-96. 1931.—In 4-10% aqueous solution of iron alum, small pieces of Mazzard roots cause darkening of the solution in a few minutes. Mahaleb causes no change. The reaction is ascribed to "differential quantitative presence of tannic substances."

7992. **NICOLAISEN, R., und O. ROLTE. Der Einfluss der Düngung auf die Eignung der Gurken für Konservierungszwecke.** *Mitteil. Deutsch. Landw.-Ges.* 45 (30): 656-658. 1930.—Artificial fertilizer, to some extent, can serve as a substitute for heavy applications of barnyard manure. The increased yield from the manure is compensated by the lower cost of the fertilizer. No injury to quality follows the use of artificial fertilizer. Omitting an essential nutrient is disadvantageous to the grower and also impairs the pickling quality. Unbalanced amounts of N affect both quality and yield. Different N compounds do not show different effects on either quality or yield. Increasing potassium beyond a certain limit results in decreased quality and yield, while increased amounts of phosphoric acid had a favorable effect on these. Detrimental effects on other characters were not established.—*Authors' conclusions* (*transl. by T. M. Currence*).

7996. **SLATE, G. L. Filberts.** *New York State* [*Geneva*] *Agric. Exp. Sta. Bull.* 588. 32p. 3 fig. 1930.—This is a rather detailed account of the climatic and soil requirements of filberts, their planting, fertilizing, pruning, propagation, insect pests and diseases, harvesting, pollination, varieties. The information and recommendations are based on observations made over a period of 5 yr. in an extensive variety collection maintained by the Station.—*G. L. Slate.*

7997. **SPINKS, G. T. Self-fertility and self-sterility in cider varieties of apples.** *Ann. Rept. Agric. & Hort. Res. Sta. Univ. Bristol* 1929: 28-33. [1930].—With each variety some of the flowers were tagged and self-pollinated while others, in like positions, were tagged and left to be open-pollinated. 2 varieties set nearly as well when selfed as when exposed to open pollination, 7 varieties set enough from selfed flowers to be listed as slightly self-fertile, and 4 varieties set no fruit, or very few, from self-pollination. The records cover 4 yr.—*W. H. Chandler.*

7998. SWARBRICK, THOMAS. The nutrition of fruit trees. IV. Some observations upon the growth and seasonal cycle of food reserves in apple trees. *Ann. Appl. Biol.* 17(3): 681-686. 1930.—The observed growth phenomena of a plant are regarded an indices to a previous physiological condition. Yield considered as a primary criterion of a cultural treatment may give misleading conclusions and obscure significant diagnostic growth features. The seasonal starch cycle is shown to begin in February by a disappearance. Starch reappears in March and begins again to disappear when growth starts in spring. Subsequent reappearance is associated with falling off in shoot growth. All these phenomena occur in a basipetal direction. Internal condition is discussed in relation to external growth features. It is shown that in general, and for the variety, a long narrow leaf is indicative of a high carbohydrate or low N condition, whereas a broad short leaf is indicative of low carbohydrate or high N conditions.—*T. Swarbrick.*

7999. SWARBRICK, THOMAS. Root regeneration upon transplanted apple rootstocks. *Ann. Rept. Agric. & Hort. Res. Sta. Univ. Bristol* 1929: 40-46. 3 pl. [1930].—On October 15, 1928, 100 stocks of Malling Type 13 were removed from the stool beds, more than a month earlier than in nursery practice. The larger stocks were cut back to 20 inches, the smaller to 8 in. Leaves were not removed from the parts left, but fell within 14 days after planting. On half of the smaller and half of the larger stocks all the roots were removed to the bark. The other half received no root pruning. New root formation had begun by Nov. 15. Thick, white, fleshy roots had started from the stems of all stocks. Before January 18 the ground had frozen rather deep, but the number and length of new roots had increased considerably since November 15. By March 20, stocks from which all roots were removed had more new roots from the stem, but stocks that had no root pruning had small, thread-like, sharply-pointed roots growing from the old. At this date buds were still dormant. By May 28, root growth had become rapid. In addition to the elongated roots there were new slender pointed roots just starting from the older parts of the thick, white, fleshy roots. These fleshy roots were rounded at the apex. The stocks from which no roots were removed at transplanting still had fewer thick, fleshy roots from the stem, but enough thread-like roots from the old roots to make their total root systems considerably the larger.—*W. H. Chandler.*

8000. TANAKA, TYÔZABURÔ, and YUICHIRÔ TANAKA. Nippon ni okeru Kankitsu no Hanshoku. [Propagation of citrus fruits in Japan.] *Kankitsu Kenkyû* [*Studia Citrologica*] 3(2): 197-207. 1930.—The trifoliate orange (*Poncirus trifoliata*) and Yuzu (*Citrus junos*) are commonly employed as the rootstocks for commercial species of citrus fruits in Japan, the latter being more deep-rooted and non-dwarfing, but they are equally hardy and resistant to enemies. The former is earlier in germination and more rapid growing at the beginning, but its growth is greatly retarded within a few years from the start, causing much dwarfing of the top. The growth of the Thomson navel orange, Maltese blood orange, and the Hyûganatsu (*C. tamurana*) is greatly hindered by using the trifoliate orange as the rootstock, and this defect is proved to be overcome by approach grafting the Yuzu root on the side of the weakened plant. In the warm regions of Japan, the Yamamikan (*C. intermedia*) is successful as a rootstock, and the Sunki (*C. sunki*) is valued in Formosa as a stock for all kinds of citrus fruits. A table is appended to show the result of a congeniality test of 28 kinds of citrus fruits through reciprocal grafting.—*T. Tanaka.*

8001. UPSHALL, W. H. Investigations on the propagation of apples from root cuttings. *Proc. Amer. Soc. Hort. Sci.* 26: 80-81. 1929 (1930).—Apple variety root pieces which have given a poor stand of plants because of their frequent failure to form new roots have been induced to root more readily by grafting on them a piece of a 1 yr. apple seedling as a "nurse top." Activity of amylase and catalase is greater in the 1 yr. seedling roots than in the variety roots but no consistent differences in respiration and rate of disappearance of food reserves in propagation tests have been found. Gum forms quickly in the vessels and acts as a barrier to water conduction in these channels.—*W. H. Upshall.*

8006. AUSTIN, LLOYD. Breeding pines for more rapid growth. *Jour. Heredity* 19(7): 288-301. 7 fig. 1928.—The Eddy Tree Breeding Station was established at Placerville, California, in 1925 for carrying on long-time experiments in breeding and selection with timber trees, particularly pines and walnuts. To locate the individual trees of *Pinus ponderosa* that have the greatest inherent vigor, progenies of several hundred trees are being grown in the nursery, and seed from 800 individual trees widely scattered throughout the range of this species is being sought. Selections for vigor have been made in forest nurseries. Seed has been obtained of 87 species and important varieties of pines, and it is hoped to get the seed of about 30 other pines which occur in various parts of the northern hemisphere. Several seedlings have been secured of two species crosses, *Pinus ponderosa* × *P. sabiniana*, and *P. ponderosa* × *P. montana*. The set of cones resulting from the 1927 pollination work indicates that considerable seed will be harvested in the fall of 1928 from 18 or more species crosses, including crosses of *P. ponderosa* and *P. radiata* with most of the important timber pines of the Southern states. Pine pollen has been obtained from 23 states and from Canada, Mexico, Guatemala, and the Philippine Islands.—*L. Austin.*

8007. BARBEY, A. A travers les forêts de pinsapo d'Andalousie. Etude de dendrologie, de sylviculture et d'entomologie forestière. [Through the pinsapo forests of Andalusia.] 110p. Portrait. 41 pl. Libraire Agricole: Paris; Jules Duculot: Gembloux, Belgium; 1931.—This volume is published in memory of Edward Boissier, who nearly a century ago visited the forests of *Abies pinsapo* in the Sierra de las Nieves, northeast of Gibraltar. The preface, by L. Pardé, reviews Barbey's experiences in

the pinsapo region, dwelling especially upon the utilization of *A. pinsapo* as an ornamental tree. Unlike other *Abies* spp., the glaucous needles are arranged spirally. The seeds planted by Boissier at Geneva in 1838 have produced magnificent trees 20 m. high and 1.30 m. in diam. In Paris the tree is hardy, though sometimes killed back by frost, but farther north plantings suffered severely in the ice storms of 1928-1929. The species is not hardy in northern Europe. It should be especially valuable for the Mediterranean region. Except for the recently discovered var. *maroccana* Ceballos et Bolanos, the tree is confined to not more than 1200 ha. on the northeastern slopes of the Sierra Berneja, S. del Pinar, and S. de las Nieves in southwestern Spain. Browsing by goats and sheep,—added to the damage by autumn hurricanes, dry summers, inroads of charcoal-burners, and insects,—is causing rapid extinction of this valuable timber tree. The picturesque village of Ronda at the base of Sierra de las Nieves was visited by Boissier in 1837 and in retracing his grandfather's footsteps, Barbey gives us reminiscences of the famous botanist, including letters, extracts from Boissier's rare original account of *A. pinsapo*, facsimile pages of Bowles' "Introduccion a la historia naturel, y a la geografia de España" (1775), reproductions of Boissier's type specimen and of Heyland's illustrations of *A. pinsapo*. There are detailed accounts of the individual forests, and notes on the flowering plants covering the desolate lower mountain sides. The latter portion (p. 94-110) is devoted to forest entomology and to a bibliography. *Termes lucifagus** Rossi (Neuropt.) lives on the dead wood. The following species of Coleoptera occur on *A. pinsapo: Ergates faber** L., which lives primarily on resinous material and is unknown in the *A. pectinata* region of Central Europe; *Callidium bajulus* L., whose larvae feed on twigs; *Anthaxia sepulchralis** L.; *Ancylochira octoguttata** L. (?); *Buprestis flavoangulata* Fairm., frequent also in the cedars of Morocco; *Chrysobothris solieri* Lap.; *Cryphalus numidicus* Eich.; *Cryptturgus barbeyi* Strohm, the minute larvae of which perforate twigs and cause considerable damage; *Ips erosus* Woll.; *Rhyncolus elongatus** Gyll.; *Calopus serraticornis* L.; *Otiorhynchus jaenensis** St.; and *Brachyderes pubescens* Boh. The Hymenoptera *Sirex gigas** L. (Sericidae) and *Xylocopa violacea** L. (Anthophora) are noted. *Hypoclampa chrysorrhoea* Klug and *Perithous mediator* F. were also found but the hosts are unknown. Of the Lepidoptera (Pyralidae) the recently described *Dioryctria aulloi** Barb. infests the cones and severely injures or destroys the terminal buds. The insects of this area are decidedly different from those of the *Abies* forests of northern Europe and have much in common with those infesting the pines of the Mediterranean and the cedars of Morocco.—*H. K. Svenson.*

8009. BERTIN, A. Les bois du Gabon. (Mission Forestière Coloniale, Tome 2.) 2nd ed. 304p. 3 maps. 8 pl. Librairie Larose: Paris, 1929.—A list of proposed standard trade names is given for 90 spp., together with the scientific names, where known, and the other vernacular names. For 27 spp. that are relatively abundant and suitable for commercial exploitation, and for 22 others that are less abundant (comprising altogether 60-65% of the stand), there are listed trade, scientific and native names, and possible uses. Similar information is given for 22 spp. that are valuable chiefly for their seed, fruit, latex, or other by-products. Other lists show the first 49 woods classified according to use and also according to density and hardness. The physical properties of some 60 spp. are described, with notes on size of the trees and general appearance of their bark. For the present, attempts at exploitation should be directed toward the 71 trees that are listed, and the rest of the more than 1,000 woody spp. can be ignored.—*W. N. Sparhawk.*

8010. BRUTZKUS, BORIS. Rysslands skogsbruk. De naturliga och ekonomiska förutsättningarna för det ryska skogsbruket. [Russia's forestry. The natural and economic bases for Russian forestry.] *Skogen* 18(7): 157-164. 2 fig. 1931.—Russia holds 618 million has. of productive forest, or 3 times the forest area of the U. S. A. and 40% of the temperate zone forests. European Russia has 150 million has., and Asiatic Russia 468 million. From 62.5% in the northwest the percentage of forest land sinks to 4% in the southeast. Conifers predominate. Under the law of 1923 about 26 million has. were allotted to village communal forests. The more accessible forests are being very rapidly depleted, yet there is a great scarcity of wood, including fuelwood, in many parts of Russia.—*H. I. Baldwin.*

8011. BUSSE, J., C. FROMME, U. MÜLLER, V. SCHÜPFER, A. SCHWAPPACH, und HEINRICH WEBER. Handbuch der Forstwissenschaft. Bd. 3. Betriebslehre. [In: Lorey, Tuisko, Heinrich Weber, et al. 8012. EDGERTON, D[AISY] PRISCILLA. First steps in southern forest study. 30Sp. 131 fig. Rand McNally & Co.: New York, 1930. Price, $1.40.—This is a textbook of forestry, prepared for use in public schools of Mississippi.—*W. N. Sparhawk.*

8013. EDWARDS, J. P., (introduction by J. P. MEAD). Growth of Malayan forest trees, as shown by sample plot records, 1915-1928. *Malayan Forest Rec.* 9: 1-151. 1930.—Price, 4s. 6d.—The records are based on measurements of over 4,500 trees, representing the following spp.: *Balanocarpus heimii, Calophyllum wallichianum, Dryobalanops aromatica, Dyera* sp., *Hopea intermedia, Intsia bakeri, Mesua ferrea, Ochanostachys amentacea, Palaquium gutta, P. maingayi, P. rostratum, Scorodocarpus borneensis, Shorea acuminata, S. barbata, S. bracteolata, S. ciliata, S. curtisii, S. leprosula, S. macroptera, S. parvifolia, S. sericea,* and *Gordonia concentricicatrix.* As none of these produces annual rings, the growth was ascertained by means of successive measurements on marked trees, from which were computed the periods required to pass through each 12-inch girth class. Most of the spp. measured grow much faster than European trees on the best sites.—*W. N. Sparhawk.*

8014. HYDE, H. A. Welsh timber trees, native and introduced. iv+107p. 25 pl., 21 fig. National Museum of Wales and the Press Board of the University of Wales: Cardiff, 1931. Pr. 1s.—This book deals only with those trees whose timber is of commercial importance, including a number of introduced spp. The native woodlands belong to the plant association called Deciduous Summer Forest. Their origin and their decay through man's interference, and the development of forestry in Wales are sketched. The chief timber trees are described and figured, with notes on distribution, quality of the wood, and economic uses. Bibliography of 87 titles.

8015. JOLYET, A. Le dry-farming et le reboisement des friches dans la Haute-Saône. *Bull. Trimest. Soc. Forest. de Franche-Comté* 19(2): 55-68. 1931.—The greater part of the lands in need of reforestation in the Haute-Saône (France) are on exposed slopes or the undulating limestone plateau at elevations of 300-350 m. Stones are abundant on the surface and the lands are arid, owing to the shallow layer of soil, which is often less than 8 cm. deep. The principles developed in dry farming in the semi-arid United States are used as the basis for the following suggestions in reforestation practice: cultivate the soil, dig trenches 3 m. long at intervals of 1 m. along the contours, cultivate the planting holes as deeply as possible and add to the soil either $MgCO_3$ or Kainit, place stones around each planted seedling, protect the holes from solar radiation and consequent evaporation by small stone shelters or brush. —*J. Kittredge, Jr.*

8016. McCOMBS, T. H. Turpentines from pines. Turpentines from Pinus radiata and P. pinaster. *New Zealand Jour. Sci. and Tech.* 12(6): 333-337. 1931.—Yields of

gum turpentine are about ⅓ as great as from longleaf and slash pines in the U. S. A.; of wood turpentine, still less. Whether production would yield a profit is unknown. The 2 spp. are about equal in quantity and quality of turpentine yields; the product is 1st grade.

8017. MÅRN, L. MATTSSON. Bedömningsfelen vid höjd- och toppskottsmätning. [Errors in estimating height and leader length.] [German summary.] *Skogsvårdsför. Tidskr.* 29(2): 97-119. 5 fig. 1931.—A comparison of 8 men engaged in a forest survey in Central Sweden showed a maximum deviation from the mean of 19% in total height estimation for trees 12-16 m. tall, with an average variation of 0.9m. In estimating the length of the last 10 whorls for trees of the same height, the maximum deviations were ±2.6m. for spruce and ±2.1m. for pine, increasing with height of tree. The Christen hypsometer was used.—*H. I. Baldwin.*

[German summary p. 59.] 1930.—As arabinose has been recognized in the *Panax* saponin, the sugar solution from the *Camellia* saponin was again subjected to hydrolysis and arabinose was found in it. Using the Bertrand method, di- and polysaccharides were also detected. The formula for the *Camellia* saponin, earlier proposed, $C_{47}H_4O_22 \cdot C_5H_{10}O_5$, is now corrected to $C_{51}H_{90}O_{23} \cdot 2H_2O$.—*O. F. Black.*

8042. BERKELEY, C. The green bodies of the intestinal wall of certain Chaetopteridae. *Quart. Jour. Microsc. Sci.* 73(3): 465-476. 1 pl. 1930.—In the polychaetous annelids—*Mesochaetopterus taylori, Phyllochaetopterus prolifica* and *Lepidochaetopterus pottsi*—living near Nanaimo, Brit. Columbia, the intestinal cells have a green color due to contained organisms which experiments show may under certain conditions develop flagella and become motile. No nucleus, contractile vacuole or pyrenoids could be seen and the pigment is diffuse, not in chromatophores. These organisms seem to be similar to those that have been seen in *Chaetopterus variopedatus*. It is uncertain whether they are parasites or symbionts,—more probably the latter, for they could absorb waste matters of the animals and furnish the oil which is abundant in the intestinal cells. Since the annelids live in the dark, no photosynthesis takes place. The organism is tentatively classed as a member of the Chrysocapsinae with the name *Chrysocapsa* chaetopteri* (p. 475).—*A. L. Treadwell.*

8043. DEKKER, ERNST. Die Phylogenie des Phaeophyceen-Astes. *Bot. Arch.* [*Leipzig*] 27(1/2): 159-224. 1 fig. 1929.—Evidence reviewed in detail from the morphology of reproduction, from vegetative characters, and from here newly reported serological tests is in agreement in reconstructing the phylogeny of the Phaeophyceae. The class is derived from the Heterokontae. Progressive development of sexual organs and differentiation of generations take place, not once, but along each major line of evolution within the group. Sexual reproduction passes from isogamy through anisogamy to oogamy. There is a tendency toward suppression of one generation, either sporophyte or gametophyte. The reproductive cells are at first lateral on assimilatory filaments, which become reduced to paraphyses, and then tend to become associated in sori. Reduction of assimilatory filaments leads to the formation of a cortical parenchyma. The method of growth, primitively of the diffused type, becomes intercalary. The intercalary meristem tends to shift toward the apex and is replaced by an apical cell, or in another direction again becomes diffused (in Laminariaceae with a return to the intercalary position). Intercalary growth is often retained in hairs after it has been lost in the main thallus. Elaboration of new tendencies does not necessarily bring more satisfactory adaptations. At times the more complex types of vegetative and reproductive differentiation may be lost in a regression toward the simpler condition.—*I. F. Lewis.*

8044. FRÉMY, P. Myxophycées récoltées aux îles Chausey au cours de l'excursion du Laboratoire maritime de Saint-Servan du 25 Août 1926. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1928(5): 381-390. 19 fig. 1928.—An annotated descriptive list, including *Aphanocapsa* sesciacensis* (p. 383). *A. littoralis* is new to France.

8045. FRÉMY, P. Gloeocapsa polydermatica Kütz. var. duquesnayi n. var. *Bull. Soc. Linn. Normandie* 1: 92-93. 1928(1929).—From France.

8046. FRITSCH, KARL. Die systematische Gruppierung der Thallophyten. *Mitteil. Naturwiss. Ver. Steiermark* 66: 201-215. 1929.—The author maintains the primary separation of the plant kingdom into 2 "Regions"—Thallophyta and Cormophyta. His present classification of the Thallophyta, a modification of that adopted by him in his revision of Wiesner's "Elemente der wissenschaftlichen Botanik (1909)," divides the Thallophyta into 11 "Unterabteilungen": Schizomycetes, Cyanophyceae, Myxomycetes, Dinoflagellatae, SILICOPHYCEAE (n. n. for Bacillarieae or Diatomeae), Zygophyceae, Chlorophyceae, Charophyceae, Phaeophyceae, Rhodophyceae, Eumycetes. The Schizomycetes are divided into 2 classes, Eubacteria and Myxobacteria; the Eubacteria into 2 orders, Haplobacteria and Trichobacteria; the Haplobacteria into 3 families, Coccaceae, Bacteriaceae, and Spirillaceae; the Trichobacteria into 3 families, Chlamydobacteriaceae, Actinomycetaceae, and Beggiatoaceae. Except for Dinoflagellatae, an exception because of their animal affinities, names of all autotrophic "Unterabteilungen" end in "phyceae," of all heterotrophic in "mycetes." The classification here presented proceeds in general to the orders recognized, in some cases to the family.

8047. FUNK, GEORG. Die Algenvegetation des Golfs von Neapel nach neueren ökologischen Untersuchungen. *Publ. Staz. Zool. Napoli* 7 (Suppl.): 1-507. 20 pl. (1 col.) 50 fig. 1927.—The introduction (pp. 1-17) gives the history of algal studies at Naples and the relation of the projected work to a complete survey of the area. The topographic section (pp. 18-219) analyzes the various localities in groups according to their gross ecological character, assembling first on the basis of water depth and subdividing according to water circulation, salinity and similar factors. For each locality details of substratum, population, date—often for several spots and several dates of observation in a given locality—are given, with a general discussion involving seasonal or more extended and permanent floral changes. The algal flora of grottoes is presented in detail in relation to illumination. Dredging and hand sampling were employed

for shallow water. In water of moderate and of considerable depth dredging alone was available, the maximum samples being taken from about 150 meters. It appears that algae were practically absent below 100 m., and often disappeared at about 70 m. The general section (pp. 220-307) discusses the character of the vegetation under various headings, including especially gross morphology and distribution, the substratum, types of associations, periodicity and alterations in the flora. For the entire flora the Rhodophyceae constitute about 63.5%, the Phaeophyceae 22.5%, and the Chlorophyceae 14%. Tables give distribution in relation to light and depth, and the species in reproduction at various seasons. The systematic section (pp. 308-478) lists the species present, giving popular names, references to figures, types of association in which the plant is concerned, and some general notes on synonymy, distribution, and morphology. The following are reported as new (none of which are described or illustrated except as indicated): *Codiolum* dudresnayae W. Zimmermann n. sp. (descr. p. 309); *Bryopsis* monoica (Berthold Ms. 1880) nom. nov. = (*B. pulvinata* Oltmanns) (p. 332); *Derbesia* sirenarum n. sp. (p. 335); *D.* corallicola n. sp. (p. 335); PROTOTILOPTERIS (Tilopteridaceae), based on *P.* bertholdii (Berth.) gen. nov., nom. nov. (p. 359); *Gastroclonium* pygmaeum* n. sp. (p. 405); *Nitophyllum* gaiolae n. sp. (few words of description) (p. 409); *Dasya* corallicola* n. sp. (few words of description) (p. 457); *Seirospora* iridescens n. sp. (few words of description) (p. 468).—*W. R. Taylor.*

8048. **GHOSE, S. L. A curious method of reproduction in an aquatic species of Anabaena.** *Jour. Indian Bot. Soc.* 8(2): 129-130.—2 fig. 1929.—In an unidentified sp. common as "water-bloom" at Rangoon, separation of vegetative cells and even heterocysts occurs at many places in the filament, "with a jerk and rather forcibly." Division of the separated cells and segments to form new filaments is inferred. No spores were found.—*W. Dudgeon.*

8049. **GHOSE, S. L. Five more Myxophyceae from Burma.** *Jour. Indian Bot. Soc.* 10(1): 35-37. 1 pl. 1931.—Descriptions and localities of 5 forms not previously recorded from Burma: *Chamaesiphon filamentosa* Ghose; *Aulosira fertilissima* Ghose; *Rivularia natans* (Hedw.) Welw.; *Tolypothrix limbata* var. cylindrica* (p. 36), from Mandalay; and *Scytonema* leptobasis* (p. 36), from Maymyo.—*W. Dudgeon.*

8050. **KUSCHAKEWITSCH, SERGIUS. Zur Kenntnis der Entwicklungsgeschichte von Volvox.** *Arch. Protistenk.* 73(3): 323-330. 1 pl., 14 fig. 1931.—In the development of the parthenogonidia of *Volvox tertius, V. aureus* and *V. globator* a hollow cup of cells is first formed, and this turns inside out before closing over to form the characteristic hollow sphere. In *V. tertius* and *V. aureus* this happens by the turning back of the edges of the cup; in *V. globator*, by the turning out of the bottom of the cup through the open end. This is thought to indicate that the formation of parthenogonidia is homologous to a local invagination of the surface of the parent colony, reversing the normal surface relations and necessitating a turning inside out to bring the original external surface once more to the outside. Since the first secretion of jelly occurs at the same time as the turning inside out of the cup, it is believed that the 2 processes may be causally related in some way. The paper is a posthumous reprint of an earlier paper, with an introduction by N. CHOLODNY.—*L. E. Noland.*

8051. **MEYER, K. Über die Auxosporenbildung bei Gomphonema geminatum.** *Arch. Protistenk.* 66(3): 421-435. 2 pl. 1929.—This diatom is shown to be a diplobiont like other members of the Pennatae whose cytological changes have been studied. Individuals of 2 varieties of *G. geminatum* were used. Two gametes are formed in each cell. The 1st nuclear division in their formation is preceded by characteristic synaptic and diakinetic structures of the chromatic figures. Each new nucleus then contains 14 chromosomes. Division of the protoplast accompanies this first, heterotypic, division. Homoeotypic division of the nuclei follows; and a large and a small nucleus in each cell result, the latter usually disappearing but in a few instances persisting. The isogametes then unite: the cytoplasm of both mixes; but the nuclei remain separate, so that the zygote contains 2, or 3, nuclei. The zygote immediately enlarges; the large nuclei unite; and a thick wall is developed about the entire structure, or auxospore. This spore may further be distinguished from a vegetative cell by its asymmetric form and the presence of 2 chromatophores. By continuous increase in size, the protoplast bursts out of the wall as a vegetative cell of characteristic shape and with wall already formed.—*F. Drouet.*

8052. **NIELSEN, EINER STEEMANN. Einige Planktonalgen aus den warmen Meeren.** *Dansk Bot. Arkiv* 6(9): 1-13. 1931.—Diatomeae: *Bacteriastrum* tenue* (p. 2) and *Chaetoceros* pseudosymmetricus* (p. 4), Indian Ocean; *C.* malauensis* (p. 5), Celebes and Sunda Seas; *Rhizosolenia* blavyana (*Guinardia b.* Péragallo) (p. 7). Dinoflagellatae: *Diplopsalis* ostenfeldii* (p. 8), off north coast of New Zealand. Chlorophyceae: DANASPHAERA (p. 10), near *Pachysphaera,* type *D.* indica* (p. 10), Indian Ocean.

8053. **OLLIVIER, G. Sur les bromuques de divers Ceramiacees.** *Compt. Rend. Acad. Sci.* [*Paris*] 186 (18): 1232-1234. 1928.—The contents of these bladder-like cells, called bromuques by Sauvageau, give a red color (due to the presence of bromine) when treated with fluorescein. In *Antithamnion, Antithamnionella* and *Dohrniella* they are large and easily noticeable without a color test. This author has found these bromuques in many species of *Ceramium* (they are more plentiful than at first believed): *C. rubrum, C. circinatum, C. diaphanum, C. strictum, C. elegans, C. tenuissimum,* and *C. byssoideum.* They are lacking in *C. bertholdii, C. ciliatum, C. echionotum* and *C. clavulatum.*—*R. P. Hibbard.*

8054. **SCHREIBER, E. Über Reinkultur und experimentelle Auxosporenbildung bei Melosira nummuloides.** *Arch. Protistenk.* 73(3): 331-345. 1 pl., 2 fig. 1931.—This marine filamentous diatom was successfully cultivated on agar slants. Experiments on the effect of different light intensities on rate of cell multiplication show this diatom to be intermediate between the sun-adapted *Carteria* and the shade-adapted *Biddulphia mobiliensis.* Unfavorable external conditions of many sorts induce fragmentation of the filaments. Auxospore formation was inhibited by increased salt concentrations and induced by decreasing the salinity (e.g., from 4 to 1%, or from 6 to 4%) about cells that had reached the minimal size. Auxospore formation in *Biddulphia sinensis* (here described) in the North Sea in 1926 coincided with an unusual decrease in salinity.—*L. E. Noland.*

J. Sirks.*

8059. BRIERLEY, WILLIAM B. Variation in fungi and bacteria. *Proc. Internat. Congress Plant Sci., Ithaca, N. Y., 1926* 2: 1629-1654. 1929.—An introductory survey presents the present position of the genetics of microorganisms. Following is a brief criticism of present ideas of genetic phenomena, concepts and terminology in groups of organisms outside bacteria and fungi; then a critical analysis of the phenomena of variation as applied to bacteria and fungi already described. These phenomena are classified from 2 points of view; first on the basis of morphological and physiological criteria,—an arrangement of the data in phenotypic values, and secondly according to the factors of their appearance and their mode of behavior,—an arrangement of the data in genetic values. A discussion of the correlation between the 2 systems follows. Types of variation in fungi and bacteria are classified on a genetic basis and treated in relation to processes of growth and reproduction in these groups; aberrant types of genetic phenomena are considered. Fungi and bacteria are compared with other groups of organisms in respect to the types of genetic phenomena exhibited, the interpretation and classification of these types, the genetic concepts which emerge and terminology adopted. Finally avenues and directions of genetic research on fungi and bacteria are considered with the possibilities and limitations of such research.—*L. Angst.*

8063. CORNER, E. J. H. Studies in the morphology of Discomycetes. I. The marginal growth of apothecia. II. The structure and development of the ascocarp. *Trans. Brit. Mycol. Soc.* 14(3/4): 263-291. 11 fig. 1929.—I. The sterile tissue of the apothecium consists of 2 palisade layers, cortex and hymenium, and an intermediate medulla of radial and interwoven hyphae. Marginal growth is performed by a fascicle of hyphae between the cortex and hymenium. Every hypha in the growing point arises as a lateral 2-3μ wide, the growth-rate of which rises to a maximum, then falls, the fall being accompanied by branching in the proximal part and maturing of the distal part. The distal parts are transformed on the outside of the growing point into cortical hyphae, on the inside into paraphyses; the proximal parts form the medullary hyphae. The hyphal system is therefore a sympodium. The growth of the inner hyphae ceases on reaching the surface of the hymenium, but that of the outer hyphae continues for some time at a slow rate: "hairs" are cortical hyphae with a prolonged period of rapid growth. The hymenium is formed at the margin by the apposition of hyphae, the cortex by apposition and outward rotation. Paraphyses are specialized mucilage hyphae which are commonly pigmented. Cortical hyphae have no such pigment and are not mucilaginous; the enlargement of their cells forms characteristically a pseudoparenchyma supporting the hymenium. An explanation of the sympodium at the growing point is given on the assumption that the apices of the hyphae are fed from the medulla and eventually reach the limit of its nutritional range. Other points in the construction of the apothecium are considered. The hyphal system of the apothecium of *Rhizina inflata* is exceptional, for it is evidently a monopodium.—II. The chief processes in the development of the stipitate apothecium are upgrowth from the substratum, which defines the axis or stem, and marginal and intercalary hymenial growth which define the apothecium. The development of the stem is indirect in that cell-enlargement follows as a separate stage on cell formation. The tissue-pressures of cortex and hymenium are antagonistic and give rigidity to the apothecium. Likewise, in the sessile apothecium can be distinguished a primary period of upgrowth, from initiation of the apothecium to the formation of the hymenium, and a secondary period of marginal and intercalary growth. Helvelloid, cupular, lenticular, perithecioid and immarginate forms of ascocarp are interpreted developmentally, and 2 additional forms, described as turbinulate and cleistocarpic: both are angiocarpic sessile apothecia without a secondary period of development, the turbinulate with, and the cleistocarpic without, a definite hymenium. These forms are shown to constitute a developmental series. Certain series of Operculeae which are considered to be natural are briefly described.—*Author's summaries.*

8065. ENGELKE, K. Beiträge zu der Hannoverschen Pilzflora. I. Jahresber. Naturhist. Ges. Hannover, 1924/25-1928/29. No. 75. 1-36. 1930.—A list with hosts (or substrata) and localities of about 520 Ascomycetes, mostly plant parasites.

8066. GUINEA, EMILIO. Macromicetos de la Guinea Espanola recogidos por el Sr. Martinez de la Escalera.

[Macromycetes from Spanish Guinea collected by Sr. Martinez de la Escalera.] *Bol. Soc. Espan. Hist. Nat.* 31(4): 275-278. 1931.—List of about 14 fungi including *Fomes puberulum* var. microporus (p. 276).

8067. JACCOTTET, JOHN. (Deutsche Bearbeitung von A. KNAPP.) Die Pilze in der Natur. [Fungi.] 250p. 76 pl. A. Francke, A. G.: Bern, 1930.

8068. JOHNSON, MINNIE MAY. The Gasteromycetae of Ohio: Puffballs, bird's-nest fungi and stinkhorns. *Ohio Biol. Surv. Bull.* 4(7): 273-352. 1929.—This paper contains a list of the genera and spp. of the Gasteromycetae found or likely to be found in Ohio, complete descriptions for each of the genera and species with additional notes, and keys for their identification. Five orders, 28 genera, and 92 spp. are included. One genus, *Rhizopogon*, and 4 spp. (*R. roseolus, Geaster schmidelii Lycoperdon fuscum* and *L. tessellatum*), are new records for Ohio. *Pseudocolus* schellenbergiae. (*Colus schellenbergiae* Sumstine) (pp. 338-339).—*M. M. Johnson.*

8069. KALLENBACH, FRANZ. Die Pilze Mitteleuropas. *Die Röhrlinge (Boletaceae)* 1(11): 69-78. 3 pl. (2 col.) Werner Klinkhardt: Leipzig, 1930.—This part contains descriptions of *Boletus bovinus** Fr. and *B. tridentinus** Bres. with 2 colored plates, very complete descriptions and bibliography.—*C. L. Shear.*

8070. KELLEY, ARTHUR PIERSON. Mycorrhizal studies. 1. Mycorrhiza of Mont Alto nursery stock. *Jour. Forest.* 28(1): 34-41. 2 figs. 1930.—Descriptions are given of mycorrhiza found on *Picea abies, Larix kaempferi, Pinus strobus. P. rigida, P. resinosa, P. sylvestris, P. echinata, Juglans nigra, Quercus borealis maxima,* and *Fraxinus americana* grown in the forest nursery at Mont Alto, Pennsylvania. Both ectotrophic and ectendrotrophic forms were found. *Catalpa bignonioides* was without mycorrhiza.—*P. C. Wakeley.*

8071. KUSANO, SHUNSUKE. Observations on Olpidium trifolii Schroet. *Jour. Coll. Agric. Imp. Univ. Tokyo* 10(2): 83-99. 7 fig. 1929.—*O. trifolii* is an epidermal parasite on *Trifolium repens.* The article clarifies the taxonomy and takes up the details of structure and life cycle of the fungus. The fungus is typically dioecious as sexuality occurs between gametes originating from different gametangia. In gametangium and resting cell structure, and in the process of sexuality *O. trifolii* is scarcely different from *O. viciae,* but its gamete is smaller and the former will not infect the host of the latter and vice versa.—*V. O. Graham.*

8072. LUIJK, A. van. Variationsstatistische Untersuchungen an Ustilagineen. *Mededeel. Phytopath. Lab. "Willie Commelin Scholten"* 12: 36-52. 1928.—Length, width, size index (length × width) and form index (length: width) of 10,000 chlamydospores of *Tilletia tritici* were determined. The material was treated in such a way that it became possible to compare 4 formulae which indicate the importance of a difference between 2 fungi. These formulae are (1) $D/(M_1+M_2)$; (2) $D/(\sigma_1+\sigma_2)$; (3) D/mF; and (4) $D/(mF(n)^{\frac{1}{2}})$. The 4th gave very satisfactory results for length, width and size index, but not for form index. When a value of 3 or less is obtained the 2 forms compared are identical, when 6 or more is found the 2 forms are not identical, while between 3 and 6 there is uncertainty. The formula is especially important in comparing 2 fungi which developed on natural media.—*S. J. Wellensiek.*

8073. LUND, AAGE. A new species of Pleotrachelus with remarks on this genus. *Bot. Tidsskr.* [*Copenhagen*] 41(3): 240-243. 1 fig. 1930.—*P. petersenii** (p. 241), Denmark, in *Oedogonium* sp. This is apparently a first record of a *Pleotrachelus* parasitic on fresh-water algae, with the exception of *Olpidium oedogoniorum* (Sorok.) De Wildem.

8074. McCULLOCH, LUCIA, and CHARLES THOM. A corm rot of gladiolus caused by a Penicillium. *Science* 67(1730): 216-217. 1928.—*Penicillium* gladioli causing a rot of corms especially destructive between 12 and 23° C. Pathogenicity has been proved by inoculation, and the connection of the sclerotia with the *Penicillium* established.

8075. MELZER, V. Nové cesty při určování hub. [New ways of determining fungi.] *Veda Prir. Mes. pro Sir. a Pest. ved Prir.* [*Prague*] 8(5): 150-157. 1 pl. 1927.—In studying the higher fungi one should pay attention not only to the microscopic characters and to an examination of the hymenium but should also observe (1) the color changes of the flesh produced by treatments with certain chemicals as $FeSO_4$, analyin water, phenol, etc.; (2) the microscopic structure of the pellicle of the carpophore, whose cells, consisting of dermatocystidia, hairs, granules, etc., have been found to be of great importance in the classification of certain genera.—*V. Melzer (transl. by F. A. Wolf).*

8076. MÖRNER, CARL TH. Discomyceten Urnula craterium (Schw.) Fr.—en för Sverige ny storsvamp. [Urnula craterium; a discomycete new for Sweden.] *Svensk. Bot. Tidskr.* 24(2): 301-310. 1 fig. 1930.—*Urnula craterium,* although common in America, is less common in Hungary, Germany, and France, and is here reported for the first time from Sweden, probably on decayed branches of hazel.—*C. T. Mörner (transl. by G. B. Cummins).*

8077. MORQUER, F. Sur la biologie de Merisma giganteus. (Fr. ex Pers.) *Bull. Soc. Hist. Nat. Toulouse* 58(1): 51-61. 3 pl. 1929.—*M. giganteus* develops in cultures obtained from cuttings, and produces spherical chlamydospores protected by a thick brown membrane. It attacks wood by causing successively oxidation of the lignin, dissociation of the ligno-cellulose complex which frees the cellulose, and finally digestion of the cellulose. The author discusses its taxonomy and biology. *Celtis australis* is a new host.—*E. J. Gilbert (transl.).*

8078. NEGRONI, PABLO. Una nueva Mucedinaceae parásita del hombre. [A new Mucedinaceae parasitic in man.] *Rev. Soc. Argentina Biol.* 6(9/10): 653-663 8 fig. 1930.—From a case of epidermo- and onycomycosis a fungus* was isolated and cultivated. It is apparently a new sp. of *Cephalosporium.*—*J. T. Lewis.*

8079. NEGRONI, PABLO. Procedimiento para cultivo monocelular. [Monocellular cultures.] *Rev. Soc. Argentina Biol.* 6(9/10): 664-666. 1930.—Spores of fungi are diluted in gelatin broth at 35°-40° C. With a Pasteur pipette a small drop is placed on a glass slide which has vaselined borders; it is spread by means of a smaller slide, as if it were a blood film, and covered with a glass with a drop of sterilized water.—The preparation is then examined with a high power lens. If one spore is found in every 2-3 fields the dilution is adequate. The slide is then taken to the incubator to solidify the glycerin. The preparation is sealed with paraffin. Each cell is marked with a circle cut in the glass with a diamond.—After 24-48 hours colonies appear which have originated from one cell and can easily be transplanted. —*J. T. Lewis.*

8080. OGATA, S. Ueber den Pollaccischen Nährboden. [In Japanese, with German summary, p. 52.] *Japanese Jour. Dermatol. and Urol.* 30(5): 442-448. 10 fig. 1930.—Pollacci's medium is more favorable than Sabouraud's for the growth of trichophyta. *Trichophytum violaceum* and *T. purpureum,* which are violet or red on Sabouraud's medium, become dark brownish red on Pollacci's agar; *T. coccineum* becomes glistening dark gray instead of red; *T. fuligineum* becomes deep dark green and readily distinguishable from *T. glabrum* and *T. violaceum.*—*From author's summary.*

8081. OVERHOLTS, L. O. Research methods in the taxonomy of the Hymenomycetes. *Proc. Internat. Congress Plant Sci., Ithaca, N. Y., 1926* 2: 1688-1712. 4 pl., 46 fig. 1929.—In addition to macroscopic features, internal, microscopical features must be considered in identification. Technique of preparing mounts is discussed. All measurements should be made immediately, to avoid shrinkage. Some of the microscopic features which may be helpful in the identification of the forms in which they occur are: cystidia, setae, gloeocystidia, vesicular cells, paraphyses, conducting cells, and hyphal pegs, diameter of hyphae, clamp connections, branching, septation, and incrustation. Tissue differentiation such

as zonation and gelatinization may sometimes be an important taxonomic feature; also the not uncommon accumulations of large crystals of inorganic matter imbedded in the tramal tissues.—*P. D. Strausbaugh.*

8082. **PAUNERO RUIZ, ELENA.** Algunos datos sobre mohos. [Some data on molds.] *Bol. R. Soc. Espan. Hist. Nat.* 31(2): 101-104. 2 fig. 1931.—Includes *Diplosporium* phoespotium* on *Pinus silvestris* (p. 102).

8083. **POEVERLEIN, HERMANN.** Die Gesamtverbreitung der Uropyxis sanguinea in Europa. *Ann. Mycologici* 28(5/6): 421-426. 1930.—The species is found in Germany, Switzerland, Netherlands, the Scandinavian countries, Latvia, Poland, Czechoslovakia, and France, and Scotland. Apparently *Mahonia aquifolium* is its only European host. The uredo stage is the most common, the aecial the least common.

8084. **RAMSBOTTOM, J.** Botanical nomenclature in relation to mycology. *Proc. Internat. Congress Plant Sci., Ithaca, N. Y., 1926* 2: 1661-1666. 1929.—International rules are regarded as necessary, and should be enforced by control in the publication of only such articles that conform to the rules. Uniformity of usage can not be secured by the adoption of a standardized list of fungous names. The difficulties involved in the making and interpreting of rules can best be met by a committee appointed to deal with doubtful cases. The fungi imperfecti, cultural strains varying with the media employed, and physiological races present difficult problems for the mycologist. The author does not offer solutions but attempts to state the problems in order that the specific mycological difficulties may be more clearly recognized. He states that these "should not be rendered more difficult through the lack of a suitable nomenclature capable of expansion."—*P. D. Strausbaugh.*

8085. **RECHINGER, K. H.** Beitrag zur Kenntnis der Pilz-Flora von Aussee in Steiermark. I. Basidiomycetes. *Ann. Naturhist. Mus. Wien* 44: 279-317. 1930.—A list of 586 Basidiomycetes observed during 1912-1929.

8086. **SARTORY, A., R. SARTORY, et J. MEYER.** Etude d'un Acrostalagmus nouveau: Acrostalagmus cinnabarinus, variété minimus. *Ann. Mycologici* 28(3/4): 269-272. 1 pl. 1930.—*A. c.* v. minimus* (p. 269), on the feathers of a decomposing crow, in "la forêt de Neuhof." Cultural characters are given.

8087. **SARTORY, A., R. SARTORY, et J. MEYER.** Étude d'une nouvelle espèce de Sterigmatocystis: Sterigmatocystis albo-rosea. *Ann. Mycologici* 28(5/6): 358-359. 6 fig. 1930.—*S. albo-rosea** (p. 358), from banana skin; locality not stated.

8088. **SARTORY, A., R. SARTORY, et J. MEYER.** Étude d'une nouvelle espèce de Sterigmatocystis. Sterigmatocystis cameleo. *Ann. Mycologici* [*Berlin*] 28(5/6): 360-361. 4 fig. 1930.—*S. cameleo** (p. 360), on a dead beetle.

8089. **SARTORY, A., R. SARTORY, et J. MEYER.** Étude d'une nouvelle espèce d'Aspergillus: Aspergillus halophilus. *Ann. Mycologici* 28(5/6): 362-363. 4 fig. 1930.—*A. halophilus** (p. 362), from a specimen of cacao.

8090. **SĂVULESCU, TR., und C. SĂNDU-VILLE.** Die Erysiphaceen Rumaniens. [Erysiphaceae of Roumania.] 82pp. 25 pl. Tipografia "Bucovina" J. E. Toroutiu: Bucuresti, also publ. in *Ann. Sci. l'Acad. Hautes Etudes Agron. de Bucarest* 1: (5-82). 24 pl. 1929.—The work includes 8 genera and 34 spp. of Erysiphaceae on 175 host plants, and is based on material collected in Roumania by the authors. Measurements are given for perithecia, asci, ascospores, conidia, and in some cases for the appendages, of each sp.; and the variations in these measurements for various hosts are recorded. The descriptions are supplemented with camera lucida drawings of asci, ascospores, and conidia and with photomicrographs of perithecia. No new spp. or forms are described as such. With some few exceptions, the nomenclature of Salmon was followed. Synonymy of each sp. is given. A key to the genera of the Erysiphaceae, a description of the 3 general types of conidia of the family, an alphabetical list of the host plants, an index to the fungous names, and a bibliography of 6 pages are included.—*B. B. Higgins.*

8091. **SAWADA, KANEYOSHI.** On the scientific name of red rust of onions. [Japanese.] *Trans. Nat. Hist. Soc. Formosa* 18: 148-163. 1928.—The rust of onions in Japan has been erroneously identified as *Puccinia porri* (Sow.) Wint. It is actually *P. allii* (DC.) Rudolphi.—*Courtesy Japanese Jour. Bot.*

8092. **SERRA, G. M.** Nota al mio lavoro intitolato "Un caso di cheratomicosi da un micete non isolato finora dall'occhio." [Note on the article "A case of keratomycosis caused by a fungus not hitherto isolated from the eye."] *Ateneo Parmense* 2(5): 477-480. 1930.—Later studies by L. Maffei have differentiated the organism from previously known species; it is described as *Cephalosporium* serrae Maffei (p. 479).

8093. **SZULCZEWSKI, J. W.** Przyczynek do zimowej mykoflory Poznania i okolicy. [Winter fungous flora of Poznań and surrounding regions.] [German summary.] *Kosmos* [*Lwów*] 55(1/2): 233-248. 2 fig. 1930.—A list of 180, all groups represented, collected in or near Poznań, Poland, during the mild winter of 1927-1928.

8094. **TAI, F. L.** A new species of Uncinula on Acer trifidum Hook. & Arn. *Contr. Biol. Lab. Sci. Soc. China Bot. Ser.* 6(1): 1-4. 1 pl. 1930.—*U. nankinensis**, near Nanking; type in Univ. of Nanking.

8095. **UÑAMUNO, LUIS M.** Reliquiae Fragosoanae. *Bol. R. Soc. Espan. Hist. Nat.* 31(3): 197-199. 1931.—An annotated list of fungi including: Uredinales (5 spp.); Pyreniales (3); Sphaeropsidales (2); Hyphales (3). Many of these are new for the Spanish flora.

8096. **WESTON, W. H., Jr.** Sclerospora butleri, a new species from Nyasaland. *Phytopath.* 21(1): 125. 1931.—Abstract. On the wild grass, *Eragrostis aspera.*

8097. **YAKUSHIJI, E., und M. KUMAZAWA.** Isaria atypicola Yasuda und ihre neue Wirtsart, Latouchia japonica Kishida. (In Japanese.) *Bot. Mag. Tokyo* 44 (524): 464. 1930.—*Isaria atypicola*, endemic to Japan, was found distributed in Ishigaki Island of Loochoo. Its host is probably *L. japonica*, a trap-door spider, which has not been noted as a host of this fungus.—*M. Kumazawa.*

8098. **YOSSIFOVITCH, M.** Le mécanisme de la séparation des périthèces chez les Erysiphaceae et le rôle des fulcres. *Rev. Path. Végét. et Entom. Agric.* 16(4/5): 132-140. 1929.—Perithecia of *Uncinula*, *Microsphaera*, and *Podosphaera* stick to the leaves, even when dry, and are not blown away but are easily washed away by rain drops. They stick where they fall.—*J. Dufrenoy.*

MYXOMYCETES

8099. **SKUPIENSKI, F. X.** Sur la coloration vitale de Didymium nigripes (Fr.). Note preliminaire. *Acta Soc. Bot. Poloniae* 6(3): 203-213. 1 col. pl. 1929.—The author employed neutral red, methylene blue, and Janus green. *D. nigripes* grew well in the presence of a solution containing a mixture of equal parts of 1:5000 neutral red and methylene blue. The neutral red produced an intense color in the sporangia and methylene blue stained the stipes. This double staining of the parts in no way interfered with the production of fructifications. The vacuoles and metachromatic corpuscles absorbed the neutral red while the bacteria imprisoned within the vacuoles took the Janus green stain.—*F. X. Skupienski (transl. by F. A. Wolff).*

LICHENES

8100. **ALLEN, ARTHUR F.** Some Cladoniae from the valley of the Cap Chat River and vicinity, Gaspé Peninsula, Quebec. *Rhodora* 32(377): 91-94. 1 pl. 1930.—A list of species collected by author, with localities; it includes *Cladonia* conista Robbins (*Cenomyce fimbriata β conista* Ach.) and *C.* invisa Robbins (p. 93), Quebec. —*S. F. Blake.*

8101. **ANDERS, JOS.** Die Flechtenflora des Kummergebirges in Nordböhmen. *Naturwiss. Zeitschr. Lotos* 76(8/12): 315-325. 1928.—The author classifies the

lichens according to substrate, and into the following groups: soil, sod, bark, wood, and rock lichens, and parasites. Among the soil lichens, the most prevalent are the *Cladonia* spp. (66), *Cetraria* spp. (4), and the crustose lichens, *Lecidea uliginosa* Schrad., *L. granulosa* (Ehrh.) Schrad., and *Icmadophila ericetorum* (L.) A. Zahlbr. Among the sod lichens, the author lists 9 spp. of *Peltigera*, including 2 forms, and 4 spp. of *Cladonia*. Among the bark lichens, he lists 2 spp. of *Alectoria*, 2 of *Usnea*, 6 of *Parmelia*, 2 of *Parmeliopsis*, 3 of *Cetraria*, 2 of *Xanthoria*; and 3 of *Cladonia*. The older trunks and branches of trees were abundantly covered with lichens. Among the wood lichens, i.e., those found growing on old fence rails and decaying trunks, the most common was *Psora ostreata* f. *myrmecina* (Ach.) Schaer.; 11 other spp. occurred on wood. The rock lichens include 43 spp. on sandstone free from lime, and 22 on sandstone containing lime; among the latter, *Staurothele succedens* Rehm. Among parasites, he lists the lichens that grow on living mosses or on other living lichens, in the end destroying them; 4 spp. are listed, among them *Cladonia pyxidata* v. *pocillum* (Ach.) Fw. and *Icmadophilum ericetorum* (L.) A. Zahlbr.—*C. C. Plitt.*

8102. BACHMANN, E. Stereocladium tiroliense Nyl., eine selbständige Stereocaulonspezies. *Hedwigia* 66(2): 157-162. 8 fig. 1926.—*Stereocaulon* tiroliense (*Stereocladium t.* Nyl.) (p. 157), Erzgebirge (Czechoslovakia). The species is minutely described.

8103. CHOISY, M. Qu'est ce que Pseudoleptogium? [What is Pseudoleptogium?] *Arch. de Bot.* [*Caen*] 1: 139-141. 1927.—The author discusses the confusion existing in this genus.—*M. Choisy* (*transl*).

8104. CHOISY, M. Tératologie curieuse de Parmelia prolixa. *Arch. de Bot.* [*Caen*] 2: 82-84. 2 fig. 1928.—Parasitized by *Discothecium*.

8115. LOESKE, LEOPOLD. Die Laubmoose Europas. II. Funariaceae. *Rep. Spec. Nov. Reg. Veg. Sonderbeiheft B* 1-120. 69 fig. 1929.—*Physcomitrella patens* (Hdw.) Br. Eur. is united with the genus *Physcomitrium* as *P.* **patens*** (*Physcomitrella p.* Hdw.) (p. 15). The genus *Physcomitrella* is eliminated. *Physcomitrella hampei* is named *Physcomitrium* **hampei*** Lsk. et Györffy in litt. (p. 21). *Physcomitrium eurystomum* f. **acuminatum** (*P. a.* Schleich.) (p. 32). *Funaria dentata* var. **mediterranea** (*F. m.* Lindb.), with f. **polygama** n. f. (based on *F. pulchella* Phil.), and var. **convexa** (*F. convexa* Spruce) Bott. in litt. (p. 61). The work being printed (but not published) in 1914, the author gives complementary "Nachträge 1915-1929." All European species of the Funariaceae are now described; also all the hybrid forms are described or at least mentioned.—*L. Loeske.* [A chapter by P. JANZEN, entitled "Die Entwicklung und Biologie von Funaria hygrometrica" (pages 72-111, and with 26 microscopic illustrations of parts) is included. It describes in detail the development of each part of the plant.]

8116. LUND, P. J. Bidrag til Vendsyssels mosflora [Denmark]. II. *Bot. Tidsskr.* [*Copenhagen*] 41(4): 304-309. 1931.—Lists of liverworts (25 spp.) and peat (15) and leafy (62) mosses. *Jungermannia heterocelpos* is new to Denmark.

8117. TIWARY, N. K. A preliminary note on the germination of the spores of Cyathodium sp. *Jour. Indian Bot. Soc.* 8(2): 139-143. 19 fig. 1929.—The plant was identified as *C. cavernarum* by Goebel and as *C. tuberosum* by Kashyap. Abundance of all stages of germination were found on the sides of a ditch at Benares in Aug. As the sporogonium does not dehisce, the spores germinate in situ. There is evidence of 2 or more germ pores; the germ tube emerges through one, and one or two rhizoids from others at the opposite end of the spore. This method of germination is taken as further evidence of close relationship with *Targionia*. The germ tube may give rise to a filament or to a cell mass. Sometimes the original germ tube grows out into a much elongated colorless cell, and develops a green cell mass at

the end; sometimes a colorless cell mass is produced first, and an elongated colorless cell grows out from it, producing a green cell mass at the end. A 2-sided apical cell arises earlier from a filament than from a cell mass; it is presently replaced by the mature Marchantiaceae type of initial cell. Attempts to germinate spores artificially failed, apparently because the spores must pass through a period of rest.—*W. Dudgeon.*

ANGIOSPERMAE (MIXED)

8119. BECHERER, A. Nomenklatorische Notizen. *Rep. Spec. Nov. Reg. Veg.* 28(751/755, paper 7): 53-59. 1930.—These notes deal principally with subspecific variations and transfers, some of which have been previously published. *Secale cereale* ssp. *eu-cereale* (*Triticum c.* Rasse *eu-cereale* Asch. et Graeb.) Bech.; *Silene vulgaris* ssp. *vulgaris* (Gaudin) Bech. (*S. inflata* ssp. *vulgaris* Gaudin). The author recommends that the generic name *Malachium* Fries (1828) be conserved over *Myosoton* Moench (1794) and *Malachia* Fries (1817). He lists 17 combinations in European plants, combs. not generally recognized. *Gagea saxatilis* (*Ornithogalum bohemicum* var. *s.* (Mert. et Koch)) J. A. et J. H. Schultes; the author is not "Koch." *Calluna vulgaris* (L.) Hull var. *hirsuta* (S. F. Gray) Hayek; the author is not "Presl." The name *Honckenya* used for an African genus of Tiliaceae is untenable because of priority (Ehrhart, 1788), and must be replaced by *Clappertonia* Meissner, 3 spp. of which are known: *C. ficifolia* Decne., *C.* **minor** (*H. m.* Baillon) (p. 58), and *C.* **polyandra** (*Cephalonema p.* K. Schum.) (p. 58). Among Gramineae *Phleum hirsutum* Honckeny (1782) (=*P. michelii* All. 1785) and *Festuca festucoides* (Bertol. 1804) Bech. (=*F. lachenalii* (Gmelin 1805)) Spenner.—*H. K. Svenson.*

Mag.* 153(2): Tab. 9173-9183. 1927(1929).—Hand-colored plates and descriptions are given for the following, each by Stapf unless otherwise stated: *Rhododendron calophytum** Franchet, by Stapf and F. B., China; *Gaultheria veitchiana** Craib, China, with key to distinguish it from *G. hookeri* Clarke and *G.* **rudis** (sub Tab. 9174), Szechuan; *Cyrtanthus* **rhododactylus*** (Tab. 9175), South Africa; **SIPHONOSMANTHUS**, based on *S. suavis** (*Osmanthus s.* King) (Tab. 9176), Himalaya, also *S.* **delavayi** (*Osmanthus d.* Franch.) (Tab. 9176); *Acacia rhetinodes** Schl., Australia, by Stapf and F. B.; *Salvia caerulea** Benth., S. America; *Eucnelia mooreana** Schl., Costa Rica, described with notes by V. S. SUMMERHAYES; *Cosmos diversifolius** Otto and *C.* **atrosanguineus** (*Bidens a.* Ortgies) (Tab. 9180), both from Mexico; *Briggsia amabilis** Craib, China; *Potentilla nepalensis** Hook., India; *Euonymus grandiflorus* f. *salicifolia,** China and India, described by Stapf and F. B.

8122. STAPF, O. Plants from the Royal Botanic Gardens, Kew, and other botanical establishments and private gardens. *Curtis's Bot. Mag.* 152(4): Tab. 9151-9161. 11 col. pl. 1926(1928).—Colored plates are given of the following, with descriptions by O. Stapf unless otherwise stated: *Tulipa lanata** Regel from central Asia; *Ozothamnus antennaria** Hook. from Tasmania, with critical notes on the genus; *Berberis hookeri** Lem. from India; *Solanum laciniatum** Ait. from Australia; *Paphiopedilum robinsonii** Ridley (description by Stapf and F. B.) from Malay Peninsula; *Rhododendron hippophaeoides** Balf. & Sm. (described by O. S. and F. B.) from southwest China; *Muscari armeniacum** Baker from Orient; *Cestrum* **psittacinum*** (Tab. 9158), from Central America; × *Saxifraga* **amabilis** (*S. stribrnyi* Podpera × [*S.*] *sempervivum* C. Koch.) (Tab. 9159) from southeast Europe; *Hypericum leschenaultii** from Malaya; *Guevina avellana** Molina from Chile.

MONOCOTYLEDONES

8123. PFEIFFER, HANS. Über 70 neue Namenkombinationen in einer einzigen Cyperaceengattung oder Aufnahme eines Gattungsnamens in den Index der "Nomina conservanda"? *Repl. Spec. Nov. Reg. Veg.* 27(726/733; paper 3): 85-91. 1929.—Kunth (1837) differentiated *Bulbostylis* as a genus "inter *Isolepidem* et *Fimbristylem*" with an excellent diagnosis. *Bulbostylis* has been taken up by many prominent botanists although it had been proposed (DeCandolle, 1836) for a genus of Compositae now recognized as *Brickellia*, and by Steven (1814) for a group of *Eleocharis* species. The name *Stenophyllus* (Rafinesque, 1825, and Séringe 1830) was not so well characterized, but has been accepted in several important treatments. The author shows in a tabular presentation that 5 spp. have been described under *Stenophyllus* alone, 21 under *Bulbostylis* for which combinations with *Stenophyllus* have already been made, and 74 under *Bulbostylis* alone. For this last group new combinations must be made under *Stenophyllus* unless *Bulbostylis* is conserved. The author recommends that *Bulbostylis* be conserved. The following nomenclatorial change is made: *Bulbostylis* **conspicua** (Boeck.) n. comb., vel *Stenophyllus* **conspicus** (Boeck.) n. comb., based upon *Fimbristylis conspicua* Boeck. (p. 90).—*H. K. Svenson.*

8124. SMITH, J. J. Notizen aus Reichenbachs Herbar. *Bull. Jard. Bot. Buitenzorg* 8(4): 353-369. 1927.—The au-

thor studied a number of Reichenbach's types of Orchidaceae in the Vienna Herbarium. The following are recognized, with synonyms in parentheses: *Zeuxine gracilis* Bl. 8132. LYKA, K. Schlüssel zur Bestimmung der in Schleswig-Holstein und angrenzenden Gebieten wachsenden Formen der Gattung Thymus. *Rep. Spec. Nov. Reg. Veg.* 28 (751/755, paper 8): 59-62. 1930.—A comprehensive key treatment of forms of *T. serpyllum* (L.) Briq., *T. rigidus* Wimm. & Grab., *T. parviflorus* Opiz and *T. chamaedrys* Fries. Hybrids and white-flowered forms are common within these species.—*H. K. Svenson.*

8133. MARSDEN-JONES, E. M., and W. B. TURRILL. Researches on Silene maritima and S. vulgaris: II, III, V. *Kew Bull. Misc. Inform.* 1929 (2): 33-38; (5): 145-175. 1929. 1931 (3): 118-145. 1931.—II. Details of the occurrence and descriptions of naturally occurring hybrids between the 2 spp. are given; these have now been found by the authors in Dorset, Hampshire, South Devon, and North Wales. Descriptions of probable parents found growing with some of the hybrids are also given. As previously shown, many viable seed are obtainable when the 2 spp. are crossed. The fertility on crossing the species is apparently often practically as high as that of intra-specific pollination and fertilization. Moreover, the range of variation within each species is as great, all characters considered, as the differences normally exhibited by the 2 spp. There seems thus no valid taxonomic or genetic reasons why the 2 spp. should not regularly interbreed and, indeed, amalgamate as one "polymorphic" species. And yet they have not done so, nor is there any indication that they will in the near future. Natural hybrids between them are relatively rare and occur only near the parents. Ecologically the 2 spp. are quite distinct. *S. maritima* occupies maritime habitats, especially shingle beaches and cliffs, or stony ground at considerable altitudes. *S. vulgaris* in Great Britain is an inland plant of grassy downs, arable land, roadsides, and broken ground. Hybrids occur only in the narrow zone where the species meet. It is concluded that the 2 spp. are ecologically separated and that physiological differences not obviously connected with their gross morphology keep them distinct.—III. Stock-plants of *S. maritima* used up to 1928 for breeding experiments are described, indicating that a great range of characters and character-combinations occurs in nature. An account is given of plants grown from wild seed. Intra-specific crossing largely accounts for the numerous character-combinations found in individuals of wild populations. Many characters are exhibited by the different organs within the one species; these occur in numerous combinations—indeed at present there is no reason for supposing that any theoretically possible combination does not occur in nature. Whatever linkage groups exist are apparently at times broken by crossing over. The impracticability of naming all the character-combinations (known or possible) as subspecies, varieties, forms, etc., is commented upon. For many of the characters it is impossible to assign valid reasons for accepting one or several as having superior taxonomic value over others. A tentative scheme is proposed for dealing with intra-specific variation within a polymorphic Linneon, involving the use of letters and arabic numerals. A summary account is given of the distribution of wild populations on the Chesil Beach and Overcombe Beach, in Dorset, and at Dawlish, S. Devon. Attention is called to a remarkable group of 1310 plants at the Portland end of the Chesil Beach. These form the most uniform wild population yet studied and with few exceptions agree in having a lax general appearance, narrow leaves, and much anthocyanin.—V. The descriptions, given of stock-plants of *S. vulgaris* used up to 1930 for breeding experiments, alone indicate that a great range of characters and character-combinations (here listed and considered) occurs in nature. As in *S. maritima*, there is no reason for supposing that any theoretically possible combination does not occur in nature. As for *S. maritima*, a scheme involving letter and figure symbols has been prepared and used with advantage for scoring character-combinations in wild populations. An account of wild populations growing near All Cannings Farm (Wilts), Potterne (Wilts), Barton Stacey (Hants), Guildford (Surrey), Shoreham (Kent), Bradfield (Berks), Windsor (Berks), and Chipperfield (Herts) is given.—*W. B. Turrill.*

8134. NEGODI, GIORGIO. Studio monografico sulla Silene angustifolia (Mill.) Guss. con particolare riguardo alle forme italiane. [Monograph of Silene angustifolia with special regard to Italian forms.] *Arch. Bot. Sist. Fitogeog. e Genet.* 4 (1): 40-71; (2): 138-153; (3/4): 217-277; 5 (1): 24-45; (2): 111-142. 8 pl. 1928-1929.—The species is treated broadly enough to include *S. vulgaris, S. thorei, S. alpina* and *S. maritima*. Chap. I takes up the systematic, genetic, anatomical and ecological principles which form the basis for the work, and all the criteria for delimiting the species proposed from Linnaeus to date are considered. Chap. II sets forth the results of bibliographic studies, of investigations in the herbaria and museums of Italy and elsewhere, of observations in nature, and of experimental cultivation of various forms to determine the value of the systematic entities. These are comprised in the systematic prospectus, containing descriptions of 56 entities. Chap. III discusses the genetic value of the numerous races, with especial reference to their constancy. Chap. IV deals with the behavior of F_1 and F_2 hybrids obtained artificially. Chap. V contains observations and considerations of anatomical, cytological, ecological and general nature on organs subject to polymorphism. In Chap. VI there is a full discussion of the phyletic, intracyclic and especially the distributive relations of some races. The final chapter presents some analogies between the polymorphism of *S. angustifolia* and of related species of the section *Behen*. There are recognized 4 subspecies, under which are many subdivisions each proposed as an "entita." Under *Silene angustifolia* ssp. *vulgaris* (Gaud.) Briq. appear: **vulgaris** (*S. v.* Moench) (p. 67); **pseudoleracea** (*S. venosa vulgaris* var. *p.* Graebn.) (p. 70); **leptophylla** (*Behenantha inflata l. parviflora* Schur.) (p. 71); **monticola** (*B. i.* f. *glaucescens monticola* Schur.) (p. 139); **rorida** (*S. inflata rorida* Schur.) (p. 142); **brachiata** (*S. b.* Jord.) (p. 143); **compacta** (p. 144); **luxurians** (*S. venosa vulgaris vescicaria* f. *l.* Graebn.) (p. 144); **cylindrica** (*S. venosa* v. *c.* Kuntze) (p. 145);

brachycalyx (p. 146); breviflora (*S. cucubalis* var. *b.* Rouy (p. 146); ovalifolia (*Behenantha inflata o. (vaccariaefolia)* Schur.) (p. 147); dolichopetala (*S. venosa f. d.* Zapal.) (p. 148); latilaciniata (*S. venosa f. l.* Zapal. (p. 148); quadrifida (p. 149); rubra (*S. inflata rubra* Ram.) (p. 149); rubristimmis (p. 150); macrocalyx (p. 152); angustissima (*Cucubalus angustissimus* Nocca & Balbis) (p. 153); alpestris (p. 217); zlatiborensis (*S. venosa* ssp. *vulgaris* var. *z.* Novak) (p. 219); boraeana (*S. cuculatus* f. *boracana+latifolia* Rouy & Fouc.) (p. 222); minutiphylla (*S. cucubalus boraeana* var. *angustifolia* Rouy & Fouc.) (p. 223); oreophyla (*S. venosa* var *o.* K. Maly) (p. 225); pubescens (*S. inflata p.* DC.) (p. 228); stenophylla (*S. vinosa bosniaca stenophylla* Beck) (p. 231); puberula (*S. inflata puberula* Huter, Porta & Riga) (p. 231); villosa (*S. cucubalis vesicaria pubescens* subv. *villosa* Rouy & Fouc.) (p. 232); pubigera (*S. venosa pubigera* Halacsy) (p. 232); pubiphylla (p. 233). Under *Silene angustifolia* ssp. alpina (*Cucubalus alpinus* Lam.) (p. 235) are listed: montana (*C. montanus* Vest) (p. 237); glareosa (*S. g.* Jord.) (p. 238); muscosa (p. 242); hirtiphylla (p. 242); roseo-punctata (p. 243); uniflora (*S. inflata uniflora* Otth.) (p. 243); marginata (*Cucubalus marginatus* Kit.) emend. (p. 244); microloba (*S. m.* Schott.) (p. 245); pilosula (p. 246); hirsutiuscula (p. 247); cryptopetala (p. 248). Under *Silene angustifolia* ssp. maritima (*Viscago m.* Hornem.) (p. 249) are listed: maritima typica (*S. maritima typica* Graebn.) (p. 250); lobata (*S. maritima* f. *l.* Salisb.) (p. 251); porphyrostigma (*S. m. f. p.* Nordtstedt) (p. 251); petraea (*S. inflata* var. *p.* Fries) (p. 252); tenella (*S. maritima t.* Rouy & Fouc.) (p. 253); gracilis (*S. m. f. g.* Almquist) (p. 254); bastardii (*S. b.* Boreau) (p. 254). Under *Silene angustifolia* ssp. thorei (*S. t.* Dufour) (p. 255) appear: thorei genuina (Duf.) n. comb. (p. 256); tenella (*S. cucubalis thorei tenella* Rouy & Fouc.) (p. 257).—*G. Negodi* (*transl. by H. S. Wolfe*).

8135. **OMANG, S. O. F. Die Hieraciumflora im Talgebiete Gudbrandsdalen [Norway]. II.** *Skrifter Norske Vidensk.-Akad. I. Mat. Nat.-Kl.* 1927 (2. bind, No. 4): 1-140. 1927 (1928).—This region lies in the central southern Norway and has no distinct barriers. It may be considered an extension of the Central-Swedish lowlands. The distribution of various groups of species within the region is discussed and the wider distribution of certain ones, together with the migration problems involved. It is concluded that the group shows here a high degree of endemism and that mutation has been important in producing new forms. There are recognized 441 species and varieties (a few hybrids) in the following groups: Piloselloidea, 64; Alpina genuina, 66; Alpina nigrescentia, 44; Cerinthoidea, 1; Oreada, 19; Silvatica, 140; Caesia, 24; Vulgata genuina, 33; Rigida, 9; Prenanthoidea, 31; Foliosa, 10. The last 5 are considered, together with additions and corrections to the others previously treated in Part I of the same work. An index is provided but there is no bibliography and the citations in the text are without dates. Included are the following: *H.* perichnoum (p. 24), *H.* anchirhomboides (p. 30), *H.* obtusulescens (p. 36), *H.* cineriticeps (p. 37), *H.* arizelum (p. 39), *H.* palleptum (p. 40), *H.* aegrotans (p. 41), *H.* connexuosum (p. 43), *H. ornatum* var. defiens (p. 46), *H.* poecilops (p. 50), *H.* meconopsis (p. 52), *H. subrigidum* var. exaltidens (p. 52), *H.* collettianum (p. 53), *H.* protenozum (*H. dissolutum* Dahlst., non Nägeli & Peter) (p. 55), *H.* anapsilon (p. 59), *H.* scolopodon (p. 59), *H.* chroocentroides (p. 61), *H.* furcelliferum (p. 63), *H.* basirhacum (p. 64), *H.* froesiense (p. 65), *H.* sphecodes (p. 66), *H.* epixanthoides (p. 67), *H.* megaphorum (p. 68), *H.* macripes (*H. prenanthoides* Vill. var. *parviflorum* Lindb.) (p. 70), *H.* phyllaceum (p. 71), *H.* fumatipes (p. 72), *H.* arrectulum (p. 73), *H.* lepidochnoum (p. 75) from Isfjordalen and Ormeim in Romsdal, *H. eurylophum* var. disfoliatum (p. 76), *H.* aepymetes (p. 77), *H.* parypheodes (p. 77) and var. lomianum (p. 78), *H.* carabodes (p. 79), *H.* phyllozum (p. 81), *H.* adeniscotum (p. 83), *H.* corosifrons (p. 83), *H.* sclerocomum (p. 84), *H.* lunnerense (*H. corymbosum* Fr. *flocciceps* Om.) (p. 86); *H. pilosella* sspp. psarodes (p. 88), niveotomentosum (p. 89), oblonguliceps (p. 89) and furvocanulum (p. 90); *H. lampranthum* var. sclerochaetum (p. 92), *H.* pyrrhopum (p. 92), *H.* anisadenium (*H. heteradenium* Om.) (p. 95), *H. stiptotrichum* var. fobergense (p. 96), *H. semicrispum* var. pammeces (p. 97), *H.* sinulosum (p. 97), *H. praematurum* var. euglossiforme (p. 99), *H.* haplophyllum (p. 100), *H. lithophilon* var. hjerkinnense (p. 101), *H.* coctile (p. 101), *H.* eriphalium (p. 103), *H.* psilozum (p. 105), *H. transientiforme* var. lomotocum (p. 106), *H.* euryclonum (p. 106), *H.* parapolium (p. 108), *H.* phelleiotes (p. 110), *H. saxifragum* var. latificum (*H. latifrons* Om.) (p. 111), *H.* orthohprixum (p. 112), *H.* acmaeophyton (p. 112), *H.* monolaephum (p. 115) from Opdal, *H.* amathophilon (p. 116), *H.* odontomeles (p. 117), *H.* chalarum (p. 119), *H.* argillosum (p. 120), *H.* nealolepis (p. 121), *H.* obliquans (*H. subdiminuens* Om.) (p. 123), *H.* scopelophyes (p. 123), *H.* eulissum (p. 125), *H.* multicium (p. 126), *H.* trilophum (p. 127), *H.* hypolizon (*H. subsparsidens* K. Joh. var. *spathuligerum* Om.) (p. 130), *H. lepistoides* var. argutifolium (p. 130), *H. mundulum* var. scobuense (p. 131), *H.* dombosense (p. 131), *H.* curtifrons (132), *H.* iconicum (p. 133), *H.* habrodes (p. 134), *H.* praevittatiflorum (*H. praevittatum* Om.) (p. 136), *H.* capnochroum (*H. capnodes* Om.) (p. 136), *H.* cathaemum (*H. acanthodon* Om.) (p. 136), *H.* exochum (*H. pseudorosulatum* Om.) (p. 136), *H.* plesicomum (*H. aricomum* Om.) (p. 136), *H.* loxodon (*H. craspedotum* Om.) (p. 136), *H. oblongulare* Om. is a synonym of *H. lyratum* Norrl., *H. melanoxanthum* Om. of *H. epixanthum* Om.; *H. poliobaptum* Om. and *H. crocydograptum* Om. probably are varieties of *H. oblaqueatum* K. Joh. *H. legnodes* Dahlst., *H. erectifrons* Zahn, *H. adenozum* Om., *H. chnootum* Om., *H. hemiodes* Om. and *H. sinulosum* Om. are described in full. *H. leucomelanides* Om. is referred to the *caesia* group instead of the *silvatica*. Other synonymy is indicated but it is not clear whether or not it has been published previously.—*O. A. Stevens.*

8136. **OMANG, S. O. F. Sogn Hieracier med en orientering i utbredelses- og vandringsforhold. [The Hieracium flora of Sogn, S. central Norway, with an orientation of the conditions of distribution and cultivation.]** *Nyt. Mag. Naturvidensk.* 67: 231-499. 1929.—This study, the result of 2 years' collecting, embraces 373 forms from Sogn. A distributional table is given. The flora is divided into 3 elements: the west-coast flora, the dale flora, and the lowland flora. A chapter is devoted to the Hieracium flora of the regions adjacent to Sogn, and one deals with the adventitiousness of *H.* in Sogn. Piloselloidea: *Hieracium pilosella* ssp. tanycranum (p. 259); *H. p. pilocanum* var. oblongoniveum (p. 260); *H. p.* sspp. albocanens (p. 260), artellum (p. 261), expolitum (p. 261), albofurcatum (p. 263), perniveum (p. 264), poliodes (p. 265), sanguineostriatum (p. 265), perpallidum (p. 266), nudiusculum, nitidulum (p. 268), and meruliceps (p. 269); *H. p.* ssp. *m.* vars. minutellum (p. 271) and olavi (p. 272); *H. p.* ssp. perflexile (p. 272) and f. sveioensis (p. 273); *H.* amblycolum (p. 275); *H.* hyperadenodes (p. 278); *H. croceum* var. semicroceum (p. 279); *H. scissicaule* var. caniusculum (p. 281). Archieracia: *H.* anemostrophum (p. 284); *H. platymeles* var. seltuftense (p. 286); *H.* tyrvenutense (p. 286); *H.* reinungense (p. 288); *H. scoliodon* var. nervosum (p. 290); *H.* capaciceps (p. 290); *H. stenomischum* var. contristatum (p. 291); *H.* allothigenes (p. 292); *H.* fascigerum (p. 295) and var. linearifrons (p. 295); *H. tumescens* var. tumidiusculum (p. 297); *H. radinum* var. exaetum (p. 298); *H.* macropodum (p. 299); *H.* ulotetodes (p. 301); *H.* subpulliceps (p. 302); *H.* tanysphyrum (p. 304); *H.* oligolophum (p. 305) and vars. pauperatum (p. 306) and fortunense (p. 307); *H.* cephalothales (p. 308); *H. schmidtii* sspp. praefloccellum (p. 310), ordalicum (p. 311), cuphodes and ambleanum (p. 312); *H.* chromorhantum (*H. tinctum* Dahlst. in sched.) (p. 314) and var. oxybelodes (p.

315); *H. saxifragum* ssp. leptophalium (p. 319) and f. aurlandica (p. 320); *H. s.* ssp. mischotum (p. 323); *H.* mischotopsis (p. 325); *H.* oreades var. aglaum (p. 327); *H.* pampsiloides (p. 328) and vars. gaupnense and pseudosympycnodes (p. 329); *H.* phyllopleon (p. 329); *H.* pernobile (*H. acutum* var. *p.* Blytt) (p. 330); *H. norvegicum* ssp. polymiantum (p. 332) and stibarum (p. 333). Vulgata: *H.* mjoemense (p. 336); *H.* phytomanum (p. 338); *H. glaucovatum* var. paratocoides (p. 340); *H.* neurosteptum (p. 343); *H.* larophyllum (p. 343); *H.* cuneolascens (p. 345); *H.* heibergianum (p. 348); *H.* subnorulum (p. 351); *H.* megethes (p. 352); *H.* cathaemactum (p. 354); *H.* praecurvescens (p. 356) and var. axiadenium (p. 357); *H.* aristrotum (p. 359); *H.* holophyes (p. 360); *H.* chlaniscotum (p. 361); *H.* leucocestum (p. 362); *H.* paramecolepsis (p. 363); *H.* parcicrinoides (p. 364); *H.* myurolepsis (p. 366); *H.* anaspilotum (p. 369); *H.* borgundense (p. 372); *H. dissimile* vars. norenense, actites (p. 375) and hoidalicum (p. 376); *H.* melannephes (p. 376); *H.* talariscodes (p. 378); *H.* pachylopum (p. 380); *H.* squamulare (p. 383) and var. eseense (p. 384); *H.* pantolum (p. 385); *H.* prophantum (p. 386); *H.* nitentiforme (p. 390); *H.* pardalotum (p. 391); *H.* paraloides (p. 392); *H. uncotum* var. extractum (p. 394); *H.* catoxyides (p. 395) and var. fuscisquamum (p. 396); *H.* grisellescens (p. 397); *H.* coniatum (p. 397); *H.* dilucidiusculum (p. 399); *H.* phyllophidum (p. 401); *H.* nitidicuspis (p. 402); *H.* extans (p. 403); *H. c.* var. jostedalicum (p. 404); *H.* epichloum (p. 404) and f. crispifrondiforme (p. 406); *H.* crispifrons (p. 406); *H* mitoclonum (p. 408); *H.* oblonguliferum (p. 409); *H.* confragosum (p. 410); *H.* denticulare (*H. angustatum* v. *elatum* Lindeberg) (p. 411); *H.* adetum (p. 412); *H.* turliense (p. 413); *H.* eulepodes (p. 415); *H.* leptocymatum (p. 417); *H.* semivulgatum (p. 418); *H.* hirtellosum (p. 420); *H.* mollifolium (p. 421); *H.* trichellosum (p. 422); *H.* pseudonanodes; *H.* congregarium (p. 424) and vars. dissociatum (p. 425) and hardbakkense (p. 426); *H. orarium* var. desidens (p. 426); *H.* schematodes (p. 429) and var. leikangerense (p. 431); *H.* ethnophyton (p. 431); *H.* anisoches (p. 433); *H.* aequabile (p. 434); *H.* lachnaeum (p. 437). Foliosa: *H. crocatum* var. actaeum (p. 478); *H.* phyllothames (p. 480); *H. angustum* vars. restricticeps and ampliusculum (p. 482).

8137. PELLEGRIN, FR. La flore du Mayombe d'apres les recoltes de M. Georges Le Testu. Deuxieme partie. *Mem. Soc. Linn. Normandie Sec. Bot.* 1(3): 1-83. 1 col. map, 6 pl., 13 fig. 1928.—Records spp. of the Gamopetalae (excluding Rubiaceae) and Apetalae, giving bibliography, descriptive notes, occurrence, and citation of specimens. The following are fully described (in French): *Mimusops africana* H. Lec., *M. le-testui** H. Lec., *Letestua durissima* H. Lec., *L. floribunda** H. Lec., *Gambeya nyangensis** Pellegr., *G. africana* v. oblongifolia (p. 14), *Diospyros le-testui** Pellegr., *D. nyangensis* Pellegr., *Maba mayombensis* Pellegr., *Clitandra le-testui** Pellegr., *Carpodinus* (?) *glandulosa* Pellegr., *Landolphia scandens* var. floribunda (p. 24), *Rauwolfia* mayombensis (p. 27), *R. tchibangensis** Pellegr., *Gabunia le-testui* Pellegr., *Brachystelma le-testui* Pellegr., *Strychnos ndengensis** Pellegr., *S. ngounyensis* Pellegr., *S. tchibangensis** Pellegr., *Prevostea mayombensis* Pellegr., *P.* klaineana Pierre ms. (p. 41), *Whitfieldia le-testui* R. Ben., *Crossandra gabonica* R. Ben., *Rungia le-testui* R. Ben., *R. obcordata* var. obtusa (p. 48), *Vitex ciliata* (Pierre msc.) Pellegr., *Dicliptera ripicola* R. Ben., *Sphaerothylax pygmaea* Pellegr., *Inversodicraca le-testui** Pellegr., *Tylostemon le-testui* Pellegr., *Cleistanthus* itsoghensis* (p. 60), *C.* ngounyensis* (p. 61), *Phyllanthus discoideus* var. glaber (p. 62); *Maesobotrya* tsoukensis (p. 64), *Croton dibindi* Pellegr., *Croton loukandensis** Pellegr., *C. tchibangensis* Pellegr., *Macaranga le-testui* Pellegr., *M. tchibangensis* Pellegr., *Dorstenia* le-testui* (p. 77), *D.* nyangensis (p. 78), *Trymatococcus* oligogyna (p. 79), UTSETELA (p. 80) (Artocarpaceae) based on *U.* gabonensis (p. 81). All the plants are from the region of the Mayombe, French Congo.—*F. Pellegrin.*

8138. PETCH, T. Campbellia cytinoides Wight. *Ceylon Jour. Sci. Sect. A. Bot., Ann. Roy. Bot. Gard. Peradeniya* 11(3): 269-275. 1 pl. 1930.—A re-description of the species of the Aeginetiaceae based upon fresh material or upon material preserved in alcohol is necessary before an accurate classification of the group may be made. The segregation of *Cliffordia* from *Christisonia* and of *Legocia* from *Campbellia* made by Livera in 1927 was based upon a study of pressed specimens and of paintings of the Ceylon species. Several of the generic differences given by Livera are seen not to exist when a study of fresh material is made.—*A. M. Ottley.*

FLORISTICS AND PLANT DISTRIBUTION

8139. ALMQUIST, ERIK. Floran inom Ängsö nationalpark. [The flora of Ängsö National Park, near Stockholm, Sweden.] *K. Svenska Vetenskapsakad. Skrifter i Naturskyddsärenden* No. 13. 1-47. Map. 1930.—Contains a list of species from 62 families, occurring within the park (about 180 acres). Adventive species are so indicated in the list.

8140. ALSTON, A. H. G. Roxburgh's Hortus Bengalensis. *Ceylon Jour. Sci. Sect. A. Bot., Ann. Roy. Bot. Gard. Peradeniya* 11(3): 299-300. 1930.—A work, presumably edited by Carey, entitled "A Catalogue of Plants described by Dr. Roxburgh in his manuscript Flora Indica, but not yet introduced into the Botanical Garden," dated 1813 and usually regarded as a continuation of Roxburgh's Hortus Bengalensis, was actually written later than 1813. Some of the plants listed in it are briefly discussed as to validity.

8141. BEYLE, M. Seltene Früchte und Samen der norddeutschen Flora. *Verhandl. Ver. Naturwiss. Unterhalt. Hamburg* 20: 78-92. 1928(1929).—The author presents notes on numerous plants which rarely produce fruits or seeds in this region. Some bloom too early in the spring to be pollinated by insects. In some the anthers do not open because of too low a temp. at the time of flowering. Others are near the limit of their distribution and so do not find conditions favorable for their development.

8142. CHIOVENDA, EMILIO. Flora Somala. 437p. Map, 49 pl., 3 fig. Sindacato Italiano Arti Grafiche: Rome, 1929.—As stated in the preface by GIUSEPPE STEFANINI, this work considers primarily the plants collected by him and Nello Puccioni on an expedition through Somalia (Italian Somaliland) in 1924. But first Chiovenda presents (a) a sketch of the vegetation of Somalia, considered geographically and ecologically for Southern, Middle, and Northern Somalia; (b) the affinity of the Somalian flora, listing endemic species, and then under 18 other headings those shared with other portions of tropical Africa and Asia; and (c) wild plants used in Anglo-Italian Somalia. (In the preceding parts all species of the Somalian flora are included.) There now follows, for the main bulk of the work, a detailed enumeration of the plants collected by Stefanini and Puccioni: the Dicotyledones, Monocotyledones, and Pteridophyta written by Chiovenda; the Lichenes contributed by MARIA CENGIA-SAMBO; the Eumycetes and Myxophyceae by ORESTE MATTIROLO; the Bacillariales by G. FRENGUELLI; and the Rhodophyceae by RITA RAINERI. Indexes are given both

to Latin and indigenous names. The plates illustrate certain species, in detail of herbarium specimens or in landscape views, or for Bacillariales and Rhodophyceae giving photomicrographs and drawings. The map, prepared by G. STEFANINI, shows the routes of the principal travelers who have made botanical collections in the Somalian Peninsula, including all Italian and British Somalia. Included is the following new material. I. DICOTYLEDONES. Brassicaceae: *Diceratella sinuata* var. elliptica (p. 75), *D.* psilotrichoides (p. 76). Capparidaceae: **STEFANINIA**, related to *Buhsia* Bunge, based on *S.* telephiifolia* (p. 77); **PUCCIONIA**, related to *Dipterygium*, based on *P.* macradenia* (p. 78) (the systematic position of these four genera is shown on a Latin synoptical table); *Boscia* subtussulcata (p. 81); *Cadaba mirabilis* vars. glutinosa and hirtella (p. 82); *C. longifolia* vars. scandens (Pax) and frutescens (p. 82); *Macrua* hirtella (p. 83); *M.* macrocarpa (p. 84). Moringaceae: *Hyperanthera* borziana (*Moringa b.* Mattei) (p. 85); *H.* rivae (*M. r.* Chiov.) (p. 85); *H.* longituba (*Moringa l.* Engler) (p. 86), redescribed. Resedaceae: *Reseda* migiurtinorum* (p. 87); *R. amblycarpa* var. somala (p. 88); *R.* nogalensis (p. 88). Polygalaceae: *Polygala obtusissima* var. somalensis (p. 89). Dianthaceae: **HAFUNIA** (Pterantheae), based on *H.* globifera* (p. 90), with key to genera of the Pterantheae. Portulacaceae: *Portulaca* nogalensis (p. 91), with vars. atricha, homotricha, and heterotricha (p. 92). Tamaricaceae: *Tamarix* scebelensis* (p. 93). Malvaceae: *Pavonia* minimifolia (p. 96); *Serra incana* ssp. migiurtinorum (p. 97); *Hibiscus* minimifolius (p. 98); *H.* spartioides* (p. 99); *H.* baidoense [sic] (p. 100), with var. parvifolius (p. 101); **SYNODONTOS** (p. 101), n. subg. of *Cienfuegosia; Cienfuegosia* (*S.*) chiarugii* (p. 101). Sterculiaceae: *Melhania denhamii* var. benadirensis (p. 103); *M.* (*Hymenonephros*) parvifolia (p. 103); **TRIGYNELLA** (p. 104), n. subg. of *Melhania*, including *M.* coriacea* (p. 104). Tiliaceae: **RUMICICARPUS** (Triumfetteae) (p. 105), based on *R.* ramosissimus* (p. 106); *Microcos* (*Eumicrocos*) cerasifera* (p. 107); *Grewia tenax* var. erythraea (*Grewia e.* Schweinf.) (p. 109). Zygophyllaceae: *Zygophyllum simplex* var. herniarioides (p. 110); *Z.* migiurtinorum (p. 111); *Z.* prismaticum (p. 111); *Fagonia* charoides* (p. 112); *Kelleronia* eriostemon* (p. 113); *K.* quadricornuta (p. 114); *K. revoilii* var. macropetala (p. 115); *K.* obbiadensis (p. 115); *K.* macropoda* (p. 115); *Tribulus terrestris* var. nogalensis (p. 116), with outline of *Tribulus*, subgen. **EUTRIBULUS** (p. 116) for *T. terrestris* L., and subgen. *Kelleronia* (*Kelleronia* Schinz) with key to 9 species, including *T.* eriostemon (*K. e.* Chiov.), *T.* quadricornutus (*K. q.* Chiov.), *T.* nogalensis Chiov., *T.* obbiadensis (*K. o.* Chiov.), *T.* bricchetii and *T.* macropodus (*K. m.* Chiov.), *Nitraria retusa* sspp. euretusa (*Peganum retusum* Forsk.) and tridentata (*N. t.* Desf.) (p. 118); *Balanites* (*Agialida*) racemosa* (p. 119); *B.* (*Agiella*) scillin (p. 120). Ochnaceae: *Ochna inermis* ssp. rivae (*O. r.* Engler) (p. 121). Geraniaceae: *Monsonia* uniflora* (p. 121); *Pelargonium quinquelobatum* var. migiurtinorum (p. 122). Burseraceae: *Commiphora* sulcata (p. 123). Celastraceae: *Hartogia* agrifolium* (p. 125); *Gymnosporia* obbiadensis (p. 126). Vitaceae: *Cissus dysocarpa* var. gymnocarpa (p. 129); *C.* (*Cyphostemma*) crithmifolius (p. 129); *C.* (*Cyphostemma*) phyllomicron (p. 130), with *f.* eglandulosa (p. 130); *C.* (*Cyphostemma*) sarcospathula* (p. 130); *C.* biternata* (p. 131); *C.* (*Cyphostemma*) migiurtinorum (p. 132). Anacardiaceae: *Rhus* puccionii* (p. 132); *Odina* malifolia* (p. 133); *O.* cotoneaster* (p. 134); *O.* rivae (p. 135). Leguminosae Papilionaceae: *Crotalaria* gracillima* (p. 137); *C.* (*Oliganthae*) nogalensis (p. 138); *Indigofera subulata* var. microphylla (p. 138); *I.* sesquijuga (p. 139), with var. obbiadensis (p. 139); *I.* sparteola* (p. 140); *I. phillipsiae* a) erecta (p. 140) and b) prostrata (p. 140); *I.* viridiflora (p. 140); *Tephrosia* (*Brissonia*) sulphurea (p. 142); *T.* (*B.*) filiflora* (p. 143); *T.* (*B.*) obbiadensis* (p. 144); *Sesbania* sesban (*Aeschynomene s.* L.) (p. 145), with a) aegyptiaca and b) nubica (p. 145); *Taverniera* stefaninii* (p. 146); *Alysicarpus glumaceus* var. ludens (*A. rugosus* var. *l.* J. G. Baker), with a) glaberrima and b) pilosula (p. 148); *Cylista* (*Eucylista*) nogalensis* (p. 148); *C.* (*Blepharanthera*) microphylla* (p. 149); a key to the spp. of *Cylista* is given (the genus is divided into subg. **EUCYLISTA**, with series **AFROCYLISTA** and **ASIOCYLISTA**, and subg. **BLEPHARANTHERA** (p. 151)); *Vigna triloba* var. somalensis (p. 151); *Calpurnia* uarandensis (p. 152), which is placed in subg. **MICROCALPURNIA** (p. 153 and xiv); *Erythrina melanacantha* var. somala* (p. 153). Leguminosae Caesalpiniaceae: *Caesalpinia* (*Eucaesalpinia*) erianthera* (p. 155); *Cassia* puccioniana* (p. 159). Leguminosae Mimosaceae: *Acacia* obbiadensis; *A.* pseudosocotrana (p. 161); *A.* sarcophylla (p. 161); *A.* sultani (p. 162); *A.* erythraea (p. 163); *A.* humifusa* (p. 163); *A.* puccioniana* (p. 164); *A.* paradoxa* (p. 165); *A.* caraniana* (p. 166); *A.* zizyphispina (p. 167); *A.* cheilanthifolia* (p. 168) with var. hirtella (p. 169); *A.* unispinosa (*A. asak u.* Fiori). Saxifragaceae: *Vahlia* somalensis (p. 170). Combretaceae: *Combretum* minimipetalum (p. 173). Turneraceae: *Loewia glutinosa* var. microphylla (p. 175). Passifloraceae: **CARANIA** (p. 175), related to *Triphostemma*, based on *C.* berberoides* (p. 176). Achariaceae: **COLLENUCIA**, based on *C.* paradoxa* (p. 177). Cucurbitaceae: *Raphanocarpus* stefaninii* (p. 179) with var. membranosa* (p. 180), with synoptic summary of *Raphanocarpus* Hook. f., proposing subgenera **EURAPHANOCARPUS** (p. 181), **STEFANINELLA** (p. 181 and xiv), including *R. stefaninii* and *R.* ? membranosus (*R. s.* var. *m.*), and **RAPHANISTROCARPUS** (*Momordica* sect. *R.* Baill.) (p. 181), with *R.* boivinii (*M. b.* Baill.), *R.* asperifolius (*M. a.* Cogn.); *Momordica* somalensis (p. 181); *M.* brevispinosa (*Kedrostis b.* Cogn.) (p. 182); *M.* macrosperma (*K. m.* Cogn.) (p. 182); **CUCUMELLA** (p. 183), based on *C.* robecchii* (p. 184); *Cucumis* halabarda (p. 185); **CEPHALOPENTANDRA** (p. 187), based on *C.* obbiadensis* (p. 187). Umbelliferae: *Trachyspermum copticum* var. maritimum (p. 188). Rubiaceae: *Oldenlandia* saxifragoides* (p. 190); *O.* obbiadensis (p. 191); *Pentodon* laurentioides (p. 192); *Pentanisia* microphylla (*Knoxia m.* Franch.); *Pavetta* microphylla (p. 194). Compositae: *Vernonia* (*Lepidella*) aschersonioides (p. 195); *Pluchea* nogalensis (p. 197); *P.* sarcophylla* (p. 198); *Blepharispermum fruticosum* Klatt a) typicum, b) lanceolatum (*B. l.* Chiov.), and c) lapathifolium (p. 200); **SCLEROSTEPHANE** (*Inuleae*) (p. 200), related to *Calostephane*, based on *S.* discoidea* (p. 201) and *S.* adenophora* (*Pulicaria a.* Franch.) (p. 202); *Pulicaria* (*Platychaete*) migiurtinorum* (p. 202); *P.* (*Platychaete*) aualites* (p. 203); *Kleinia* polycotoma* (p. 205); *Senecio* nogalensis* (p. 206); *Launaea* hafunensis (p. 207); *L. benadirensis* var. caulescens (p. 208). Plumbaginaceae: *Statice* carinensis* (p. 210); *S.* nogalensis* (p. 211); *Bubania* migiurtina* (p. 212). Sapotaceae: *Mimusops* angel (p. 213). Apocynaceae: *Adenium somalense* vars. caudatipetalum and crispum (p. 217). Asclepiadaceae: *Cryptolepis* (*Eucryptolepis*) migiurtina* (p. 217); *C.* (*Ectadiopsis*) stefaninii* (p. 218); *C.* (*E.*) ruspolii (p. 219); *Caralluma* (*Bucerosia*) rivae (p. 222). Borraginaceae: **ARNEBIOLA** (Lithospermeae) (p. 227), based on *A.* migiurtina* (p. 227). Convolvulaceae: *Seddera* saturejoides (p. 228); *Convolvulus* stenocladus* (p. 229); *C. hystrix* f. inermis (p. 230); *Ipomoea* (*Leiocalyx*) stenophyton* (p. 231); *I.* nephrosepala* (p. 233); *I.* (*Xerophyta*) sultani* (p. 234); *I.* (*X.*) anemophoba* (p. 235); *I. incana* f. melanoclada (p. 236); *Astrochlaena* nogalensis (p. 236). Solanaceae: *Withania somnifera* var. macrocalyx (p. 237); *Solanum bifurcum* var. baidoense (*S. b.* Chiov.); *S.* cicatricosum* (p. 238); *S.* obbiadense (p. 239); *S.* nummulifolium* (p. 240); *S.* cymbalarifolium* (p. 241). Pedaliaceae: *Pterodiscus* purpureus (p. 244). Acanthaceae: *Ruellia* bracteophylla (p. 246); *R.* galactophylla* (p. 247); *R. carnea* var. cinerea (p. 248); *Dyschoriste* lycioides (p. 249); **PARSTAMINEA**, n. subg. of *Dyscho-*

riste, with *D.* **nummulifolia*** (p. 250); *Asystasia drake-brockmanni* forms **typica** and **lejogyna** (p. 251); *Neuracanthus* (*Leucobarleria*) **argyrophyllus*** (p. 252); *N.* (*L.*) **stolonosus** (p. 253); *N.* (*L.*) **cladanthacanthus*** (p. 254); **CARTHAMICEPHALUS** (p. 255 and xiv) n. sect. or subgen. of *Neuracanthus*, with *N.* **thymifolius*** (p. 255); Sects. **EUNEURACANTHUS** and **LEUCOBARLERIA** (Lindau) (p. 255) seem also to be new in this genus, though not so labeled; **GOLAEA** (related to *Neuracanthus*) (p. 257), with *G.* **migiurtina*** (p. 257); *Barleria quadrispina* var. **linearifolia** (*B. l.* Rendle) (p. 259); *B.* **puccionii** (p. 260); *B.* **iodocephala** (p. 261); *B.* **insericata** (p. 263); *B.* **migiurtinorum** (p. 264); a key to spp. to sect. *Somalia* of *Barleria* is given; **CHAMAEACANTHUS** (p. 266) (near *Ruspolia*), based on *C.* **pumilus*** (p. 267); *Justicia* **dodonaeifolia*** (p. 268). Globulariaceae: *Cockburnia* **somalensis** (p. 271). Verbenaceae: *Cyclocheilon eriantherum* var. **decurrens** (p. 272); *C.* **physocalyx** (p. 272); *Priva* **adhaerens** (*Ruellia a.* Forsk), with var. **forskalii** (*Verbena f.* Vahl) (p. 274). Labiatae: *Erythrochlamys* **niveus** (p. 275); *Orthosiphon* **obbiadensis** (p. 276); *Coleus* **sceheli** (p. 277); *C.* **burorum** (p. 278); *Ballota* **microphylla*** (p. 280); *Leucas* **minimifolia** (p. 281). Nyctaginaceae: *Boerhaavia* **stenocarpa** (p. 283); *B.* **reniformis*** (p. 283); *Selinocarpus* **somalensis*** (p. 284). Amarantaceae: *Aerva persica* var. **bovei** (*A. javanica b.* Webb); *Dasysphaera* **alternifolia** (p. 287); *Psilotrichum* **tomentosum** (p. 288); *P.* **ochradenoides** (p. 289); *Pleuropterantha revoili* var. **rhodoptera** (p. 290). Chenopodiaceae: **LAGENANTHA** (Salsoleae) (p. 292), related to *Salsola*, based on *L.* **nogalensis*** (p. 293), with var. **papillosa** (p. 294). Polygonaceae: *Polygonum senegalense* var. **semilanigerum** (p. 295). Euphorbiaceae: *Monadenium* **lunulatum** (p. 298); *M.* **subulifolium** (p. 298); *Euphorbia* **leucochlamys** (p. 299); *E.* **migiurtinorum** (p. 300); *E.* **longispina** (p. 302); *E.* **chamaecormos*** (p. 303); *E.* **turbiniformis** (p. 304); *Phyllanthus* **spinosus** (p. 305); *Jatropha villosa* var. **pelargoniifolia** (*J. p.* Courb.) (p. 306); *J.* **nogalensis*** (p. 306); *J.* **arguta*** (p. 307); *J.* **obbiadensis*** (p. 308); *Tragia* **rhoicifolia*** (p. 310); *Tragiella* **pavoniifolia*** (p. 310). Moraceae: *Ficus* **somalensis** (*F. chanquensis* v. *s.* Pamp.) (p. 313).—II. MONOCOTYLEDONES. Velloziaceae: *Vellozia schnitzleinia* var. **brevifolia** (p. 314). Commelinaceae: *Aneilema obbiadensis* var. **angustifolia** (p. 316); *Commelina albescens* var. **hirsutissima** (p. 317). Palmae: *Phoenix* **caespitosa** (p. 317); *Hyphaene* **migiurtina** (p. 318); *H.* **carinensis*** (p. 319). Cyperaceae: *Scirpus litoralis* a) **trigonus** (p. 326). Gramineae: *Chrysopogon* **fulvus** (*Pollinia fulva*) (p. 327), with var. **migiurtinus** (p. 328); **PSEUDOZOYSIA** (p. 329), related to *Zoysia*, based on *P.* **sessilis** (p. 329); *Digitaria pennata* var. **pilosa** (p. 331); *Melinis* **vestita** (*Eriochloa v.* Balf. f.) (p. 332); *Sporobolus* **senegalensis** (*Agrostis barbata* b *senegalensis* Pers.) (p. 333), with a) **glaucifolius** (Hochst.) n. comb., b) **podotrichus** (Chiov.), n. comb., and c) **microstachyus** (p. 334); *S. indicus* var. **microspicula** (p. 335); *Dactyloctenium* **ciliare** (*Cynosurus ciliaris* Rottl.) (p. 337); *D.* **robecchii** (*Eleusine r.* Chiov.) (p. 337); *Diplachne fusca* var. **alba** (*Diplachne a.* Hochst.) (p. 337).—III. PTERIDOPHYTA. *Adiantum capillus veneris* L. alone is listed.—IV. LICHENES. Extensive list for the region, including *Melaspilea proximella* var. **lactea** Cengia-Sambo (p. 348); and *Thermutis compacta* Nyl., *Pterygiopsis atra* Wainio and *Hassea bacillosa* Zahl., new for Africa.—V. EUMYCETES. List of about 15 forms, including *Montagnites* **somala** (*M. candollei* v. *somala* Baccarini) (p. 364), and accompanied by a bibliography of the mycology of East Africa.—VI. MYXOPHYCEAE. *Lyngbya maior* Menegh. is listed.—VII. BACILLARIALES. A list of collecting stations with tables of occurrence and prevalence thereat; giving a bibliography and record of species collected, including: *Coscinodiscus* **minimus** (*C. excentricus* f. *minima*) (p. 387); *Trigonium* **formosum** (*Triceratium f.* Bright.); *Denticula elegans* var. **thermalis** (*D. t.* Kütz.); *Orthoneis binotata* f. **minor** (p. 394); *Navicula* **crucialis*** (*N. bacillaris* var. *c.* O. Müller) (p. 396); *N.* **rostrata** (*N. sphaerophora* f. *r.* O. Müll. non Ehr.) (p. 399); *Mastogloia* **stefaninii*** (p. 401); *Amphora* **veneta** var. **somalica*** (p. 403); *Rhopalodia* **musculus** (*Cystopleura m.* (Kütz.) Kuntze); *R. gibberula* (*C. g.* (Ehr.) Kuntze); *Nitzschia* **stefaninii*** (p. 405); *Podocystis* **spathulata** (*Emphyllodium spathulatum* Shadb.).—VIII. RHODOPHYCEAE. *Archeolithothamnium* **stefaninii*** (p. 409) and *Porolithon* **somaliae*** (p. 412) are included. An index to the Latin and vernacular names is appended.

8143. HAYEK, A. Prodromus florae peninsulae Balcanicae. *Rep. Spec. Nov. Reg. Veg. Beih.* 30[1](7/8): 961-1193. 1927.—A continuation of descriptive flora, with synonymy, of the Balkan Peninsula, this instalment covering species Nos. 2766 to 3089, of the family Umbelliferae, and including also additions and corrections, and an index. The following are published: *Bupleurum ranunculoides* II. **gramineum** (*B. g.* Vill.) (p. 971); *B. sibthorpianum* β **montenegrinum** (*B. falcatum* ssp. *exaltatum f. m.* H. Wolff) (p. 972); *B. s.* γ **cernuum** (*B. c.* Ten.) (p. 972); *B. s.* B. **orbelicum** (*B. o.* Vel.) (p. 973); *B. s.* D. **diversifolium** (*B. d.* Roch.) 8149. STANDLEY, P. C. Flora of the Panama Canal Zone. *Contr. U. S. Nation. Herb.* 27: [i]-x+1-416. 67 pl., 7 fig. 1928.—A brief treatment of the flowering plants of the Panama Canal Zone and adjacent territory, with keys to families, genera, and species, and running remarks on the species with especial reference to uses and vernacular names. Most of the cultivated plants are included. The accounts of several families have been contributed by specialists: Poaceae by A. S. HITCHCOCK and AGNES CHASE; Orchidaceae by OAKES AMES; Piperaceae by WILLIAM TRELEASE; Passifloraceae by E. P. KILLIP. The introduction treats the general features of the flora, under the following principal headings: physiography, flora of Atlantic and Pacific slopes and of Taboga Island, introduced plants, agriculture, vernacular names, Barro Colorado Island, history of botanical exploration. The plates, all reproduced from photographs, illustrate typical aspects of scenery and about 60 of the characteristic plants.—*S. F. Blake.*

8163. SAKISAKA, MITIDI. On the number of chloroplasts in the guard-cells of seed-plants. [In Japanese.] *Bot. Mag.* [*Tôkyô*] 43: 46-48. 1929.—In *Canna, Musa, Commelina, Tradescantia, Pharbitis, Dioscorea, Vicia* and *Dahlia* the number of chloroplasts in the guard-cells of leaves was calculated in June and July, the number per guard cell ranging from 3 to 24.

8164. SANTOS, JOSÉ K. Leaf and bark structure of some cinnamon trees with special reference to the Philippine species. *Philippine Jour. Sci.* 43 (2): 305-365. 21 pl., 12 fig. 1930.—The species studied were *Cinnamomum zeylanicum* Blm., *C. inérs* Reinw., *C. mercadoi* Vid., *C. cassia* Blm., *C. mindanaense* Elm. and *C. burmanni* Blm. Their leaves showed great variation in shape, size, thickness and texture but resemblance in anatomical structure. The structure of the bark was similar in all species. Secretory cells containing yellowish essential oil or sometimes mucilage occur in the mesophyll and midrib in leaves of all species and in the barks, which are further characterized by remarkable stone cells with one-sided thickening in the pericyclic region.—*H. D. Hill.*

8165. SAUNDERS, E. R. A chapter in floral evolution. *British Assoc. Advanc. Sci. Rept. 97th meeting* [*South Africa*]. 389-390. 1929 (1930).—The prevalent theory as to the morphology of the pistil has been that the carpels are of 1 uniform type, and "represent a leaf folded lengthwise and inwards, bearing the ovules on the conjoined margins." The author rejects this view and believes that pistils are polymorphic, and that 2 main types of carpels have been evolved: "(a) the valve or hollow type which is more or less extended laterally and, if fertile, bears the ovules either singly or in a single row on either margin; (b) the consolidated type which, if fertile, produces ovules either singly or in 1 to several rows on each flank of the midrib. The latter may show an appreciable lateral extension (semi-solid or pseudo-valve form), or it may consist merely of a column or radial plate of tissue (solid form). In ovaries of 1 carpel (e.g., *Anemone, Clematis, Potentilla, Rosa, Alisma*) the carpel is of valve form. In ovaries of more than 1 carpel, 2 kinds of carpel are usually present. Among exceptions to this generalisation may be cited *Nandina domestica* (Berberidaceae) (G2, rarely 3, of the valve type), *Fritillaria imperialis* (G3+3, all semi-solid). In the typical case one carpel type is fertile, the other sterile. Either the fertile or the sterile type, or both, may develop stigmas. When both carpel types are stigma-bearing the 2 sets of stigmas may be alike (occasional flowers in *Eschscholzia, Reseda*) or dissimilar (*Fumaria, Parolinia, Aphyllanthes, Aspidistra, Paepalanthus*). In *Aphyllanthes* both sets are functional, but as a rule this is not the case. In many instances carpel polymorphism appears to have arisen in association with considerable reduction in carpel number, as in Rosaceae (*Potentilla-Rosa* types *v.* other sections of the family), Phytolaccaceae (*Phytolacca-Ercilla* types *v.* Rivineae), Ranunculaceae (*Anemone-Clematis* types *v. Nigella*), *Alisma* v. *Butomus*. In some cases reduction has resulted in utilisation of persisting elements of those members which are suppressed in the construction of those which survive; these latter might therefore be said to arise by a process akin to synthesis. Transition from one carpel form to another may occur in allied forms (*Capsella bursa-pastoris* and *C. heegeri, Triglochin maritimum* and *T. palustris*, certain species of *Oxalis*, the median carpel pair in 2-valved and 4-valved ovaries of the Cruciferae)."

8166. SAUNDERS, EDITH R. On carpel polymorphism. IV. *Ann. Bot.* [*London*] 45 (177): 91-110. 45 fig. 1931.—This account deals with the Sterculiaceae. The author finds in the vascular anatomy a clue to various apparent anomalies in the floral structure and shows that a consistent principle underlies the variations in position of the several whorls in different genera. In all the types investigated the gynoecium is held to be composed of 2 carpel whorls, the outer carpels being solid and sterile, the inner, semi-solid and fertile. In certain Sterculieae premature longitudinal splitting results in the resolution, during the flowering stage, of the syncarpous gynoecium into separate ovaries, the individual ovary, which outwardly has the appearance of being monomerous, being, in reality, composed of $\frac{1}{2}+1+\frac{1}{2}$ carpels. It follows that the superficial likeness of the prematurely opened, flat, leaf-like ovary of *Sterculia* to a single dorsiventral leaf is not the result of morphological equivalence. On this interpretation the peculiar venation scheme ceases to be a difficulty. Genera with the full number of floral whorls were found to be consistently obdiplostemonous, this condition being due here, as in isomerous Geraniales and Ericales, to the dissimilar character of the two carpel whorls. In such sterculiaceous types sterile carpel cords, loculi and stigma rays as well as the fertile stamen members are antepetalous (*Theobroma, Dombeya, Pterospermum*). Where the perianth consists of only a single whorl of colored members (Sterculieae, *Thomasia, Fremontia*) these members are held not to be homologous with the sepals of a two-whorled perianth. Each such colored structure is regarded as corresponding to a sepal bordered on both sides by a half petal, in other words to $\frac{1}{2}+1+\frac{1}{2}$ members of a typical two-whorled perianth, and may be conveniently termed a tepal. The position of the staminal whorl(s) and of the sterile carpel cords, loculi and stigma rays is accounted for in the Sterculieae, *Fremontia, Cola, Thomasia* and *Hermannia*, which exhibit various differences in ground plan. Deduplication in the androecium of *Pterospermum* appeared to be due not to lateral branching but to successive bifurcation. Floral diagrams are given for *Theobroma cacao, Hermannia plicata, Dombeya burgessiae* and *Sterculia* (*Firmiana*) *platanifolia*.—*E. R. Saunders.*

8167. SINGH, T. C. N. Notes on the early stages in the development of the cotton-fibre and the structure of the boll and seed. *Ann. Botany* 45 (178): 378-380. 4

fig. 1931.—Contrary to Balls' findings, the number of fibers increases during the growth of the ovule.

8168. SINGH, T. C. N., and B. N. SINHA. Notes on the teratology of certain angiosperms. *Jour. Indian Bot. Soc.* 7(3/4): 99-104. 2 pl. 1928.—The paper describes: a fasciated leaf of *Boerhaavia repanda* Willd.; variation in number of floral parts in *Phlox drummondii;* 6 sepals, petals, and stamens in *Datura metel* L.; double fruits in *Trichosanthes dioica* Roxb.; a fasciated head in *Cosmos bipinnatus;* and a head of *Helianthus annuus* L. with leaflike structures in the center, regarded as highly modified florets.—*W. Dudgeon.*

8169. SINHA, B. N. The origin and evolution of the archegonium. *Jour. Indian Bot. Soc.* 7(3/4): 156-167. 1928.—The author criticizes briefly and rejects the views of GÖTZ and DAVIS, and proposes to derive the archegonium from the oogonium of *Coleochaete.* As the aquatic algae established themselves on land, a multicellular wall was produced by a process of "encapsulation" for protection against desiccation, and the primitive egg divided to produce the ventral and neck canal cells to meet the deficiency of water for the act of fertilization. Further evolution of the archegonium has been: embedding in the thallus in some Bryophyta, and reduction in number of neck and neck canal cells in Bryophyta and Pteridophyta; elimination of neck canal cells, reduction in number of neck canal cells, and progressively weak development of the ventral canal cell in Gymnosperms; and, finally, complete loss of all archegonium organization in *Welwitschia, Gnetum,* and Angiospermae. —*W. Dudgeon.*

8170. SMITH, CORNELIA MARSCHALL. Development of Dionaea muscipula. II. Germination of seed and development of seedling to maturity. *Bot. Gaz.* 91(4): 377-394. 36 fig. 1931.—The hypocotyl and primary root elongate, rupture the nucellar cap, and push aside the seed lid; the cotyledons partially emerge, turn green, and straighten up, carrying the seed with them; one cotyledon releases itself completely and the other remains attached by its tip, the 2 then diverging and young leaves appearing between them. The stem apex, which gives rise to leaves in spiral succession, gradually moves horizontally from between the cotyledons, forming a subterranean rhizome from the lower surface of which adventive roots arise; the cotyledons, hypocotyl, and primary root finally cease to function and are sloughed off the basal end of the rhizome of the now independent plant. The hypocotyl and the primary root are similar in structure, both having epidermis, cortex, endodermis, pericycle, and a diarch stele; there is no transition region in the hypocotyl, the vascular bundles being inverted where they enter the cotyledons; the cotyledons, with stomata and stellate hairs on both upper and lower surfaces, have a median collateral endarch vascular bundle from which 2 or more lateral branches extend. The rhizome appears to consist of an agglomeration of overlapping undiverged leaf bases with several vascular bundles coursing through them. The stele of the root of a young plant is usually tetrarch, whereas the stele of the root of a mature plant is most often octarch. The root hairs, which begin to form a few mm. behind the growing point, soon turn brown and become thick-walled, often persisting throughout the life of the root. Of the microchemical tests used to determine the composition of their cell walls, the chromic acid test for cutin alone gave positive results. They appear, therefore, to be vestigial structures. The evidence gained from a comparative study of the development of *Dionaea* and the plants closely related to it indicates that *Dionaea* should be placed in the family Droseraceae and in the order Sarraceniales.—*Author's summary.*

8171. SMITH, ORA. Factors associated with abortion and intersexual flowers in the eggplant. *Proc. Amer. Soc. Hort. Sci.* 27: 500. 1930(1931).—Abstract.

Map. 1930(1931).—A fossil treetrunk, *Dadoxylon* sp., nearest *D. arberi* Seward, is recorded from the Kalahari sandstone (Tertiary) resting on denuded Karoo sandstone (Stormberg Triassic) from which it is almost certainly derived.

8178. RAMA, L. Occurrence of Lithothamnion in the South Indian Cretaceous. *Nature* [*London*] 128(3223): 225-226. 1931.—First record from the Cretaceous of India. One of the forms present is identified as *Archaeolithothamnion* sp.*

8179. WHITE, DAVID. Flora of the Hermit shale, Grand Canyon, Arizona. *Carnegie Inst. Washington Publ.* 405. vi + 219p. 55 pl. 1 fig. 1929. Pr. $2.50.—A general description of the rocks in the upper Canyon walls, in descending order, is given. The fossil plant remains from the Hermit shale, which embraces the upper part (250-300 ft.) of the great red beds series of the Canyon, are described and illustrated in detail, together with 2 types of borings, possibly made by worms, and indistinct impressions supposed to have been made by some crustacean. The land flora, composed mostly of pteridosperms and conifers, is unique in its composition, since it combines representatives of the cosmopolitan Permian flora of western Europe and eastern America, with representatives of the Gondwana floras of the Southern Hemisphere and of the mingled Gondwana and very late Lr. Permian or Up. Permian plant life of the Ural and central Asiatic regions. Several forms are directly connected with Uralian types; some are not only congeneric, but are specifically closely related to species found in Australia, S. Africa, and Argentina. No Pennsylvanian genus except *Sphenophyllum* has yet been found. One pteridospermic genus related to *Callipteris*, 2 genera possibly pteridospermic, and 1 coniferous genus are new, besides 2 new generic types of borings. The flora, a small one, is stunted, and rather distinctly xerophytic. On the basis of its characters and of the criteria afforded by the sediments, the conclusion is reached that the plants lived along a series of very shallow, low-gradient arroyos, traversing a great plain of red silts under a semi-arid climate, with torrential rains at times and hot dry seasons in which the water was greatly reduced. Molds of salt crystals are found associated with plant remains. No carbonaceous residues are present. In age, the Hermit shale and its flora are referred to a stage very high in the Lr. Permian, the belief of the author being that they do not long antedate the beginning of the Up. Permian (Zechstein) stage.—*Courtesy Carnegie Inst. Washington.*

Forms new to science include Algae, Cyanophyceae, *Rivularites* permiensis* (p. 41); Arthrophyta, Sphenophyllaceae, *Sphenophyllum* gilmorei* (p. 44); Pteridospermaphyta, Callipterideae, *Callipteris* arizonae* (p. 50); SUPAIA (p. 54), near *Callipteris*, related to the Gondwana floras, type *S.* thinnfeldioides* (p. 62); *S.* rigida* (p. 64); *S.* sturdevantii* (p. 65); *S.* merriami* (p. 67); *S.* compacta* (p. 69); *S.* anomala* (p. 71); *S.* linearifolia* (p. 72); *S.* breviloba* (p. 74); *S.* subgoepperti* (p. 75); *Brongniartites* ? yakiensis* (p. 79); *B.* ? aliena* (p. 84); YAKIA (p. 86), probably related to *Callipteris*, erected for *Y.* heterophylla* (p. 86); Taeniopterideae, *Taeniopteris* angelica* (p. 93); Coniferophyta, Araucariaceae, *Walchia* dawsoni* (p. 99); *W.* gracillima* (p. 100); *Voltzia* dentiloba* (p. 105); Taxales, PALEOTAXITES (p. 107), erected for *P.* praecursor* (p. 107); Pinales ?, *Brachyphyllum* arizonicum* (p. 109); *B.* tenue* (p. 110); *Pagiophyllum* dubium* (p. 111); and the following fruits of uncertain affinities: *Cyclocarpon* angelicum* (p. 112); and ELTOVARIA (p. 114), erected for *E.* bursiformis* (p. 114). Animals recorded from the Hermit shale include Vermes?, SCOYENIA (p. 115), erected for *S.* gracilis* (p. 115), and WALPIA (p. 117), erected for *W.* hermitensis* (p. 117). Types in U. S. Nat. Mus. A number of previously known fossil plants from the Hermit shale are redescribed and figured.

8180. [ZALESSKIĬ, M. D.] ЗАЛЕССКИЙ, М. Д. Распространение ископаемой флоры, родственной Гондванской, в пределах северной части Евразии. [Distribution of fossil flora, related to the Gondwanian, in northern Eurasia.] Известия Академии Наук СССР., Отделение Физико-Математических Наук. (*Bull. Acad. Sci. URSS., Cl. Sci. Phys.-Math.*) 1930(9): 913-930. 11 fig. 1930.—Numerous new genera and spp. are listed, without descriptions. The following are named and figured but not described: *Isiolopteris* serrata (p. 915); *Petcheria* elongata (p. 916); *Rossovites* petchorensis (p. 916), *Ginkgoites* angaridensis (p. 917), *Ginkgophyllum* vsevolodi (p. 924), *Tchirkoviella* sibirica (p. 924), SITZIA, erected for *S.* kloki (p. 929), SITZOPTERIS, erected for *S.* superba (p. 929), *Rhipidopsis* elegans (p. 930).

PALEOZOOLOGY

(Abstracts of general papers only. Abstracts of systematic and morphological papers are grouped with those of a similar nature treating of living animals.)

8181. ABRARD, RENÉ. Comparaison des faunes continentales de Bois-Gouët, du Cotentin et du Bassin de Paris. *Bull. Soc. Géol. et Minéral. Bretagne* 8(1/4): 98-102. 1927(1930).—Lists and discusses the continental mollusks of Cotentin and Loire-Inférieure, notes the presence of the mammal, *Lophiodon parisiense*, and the plants, *Nerium vasseuri* and *Euphorbiophyllum*, at Bois-Gouët, and concludes that the beds at both localities are of Lutetian Eocene age.—*B. F. Howell.*

8182. AIGNER, GUSTAVA. Silurische Versteinerungen aus der Grauwackenzone bei Fieberbrunn in Tyrol. *Verhandl. Geol. Bundesanstalt* No. 10. 222-225. 1930.—Reports the occurrence of *Encrinurus beaumonti* v. *novaki* Frech and *Monograptus lobiferus* McCoy, both new to this locality. The 1st is known from zone E of the Silurian of Bohemia and the 2nd from zones 19 to 20 of the English section of Elles and Wood.—*G. Aigner (transl. by C. O. Dunbar).*

8183. ARKELL, W. J. A comparison between the Jurassic rocks of the Calvados coast and those of southern England. *Proc. Geol. Assoc. [London]* 41(4): 396-411. 1 pl., 1 fig. 1930.—Horizons and rich faunas are compared in detail.

8184. BAKER, CHARLES LAWRENCE. Geological cross-section of Isthmus of Tehuantepec. *Pan-Amer. Geol.* 53(3): 161-174. 1 fig. 1930.—Records from the Mesozoic and Cenozoic beds of this Mexican Gulf region, undescribed plant fragments, and the mollusks,

Crioceras, Hamites, Hoplites, Astieria, Spiticeras ?, Neocomites neocomensis ?, Monotis, and *Bangia cuneata.—D. J. MacNeil.*

8185. **BERRY, WILLARD. Evidence for the spread of East Indian forms to equatorial America during Eocene time.** *Bull. Geol. Soc. America* 41(3): 351-357. 1930.—Evidence is presented to show spread across the Pacific and to show where possible that the forms spread from the East Indies towards the West Indies and the west coast of South and Central America. Anthozoa, Arthropoda, and Mollusca are discussed. Foraminifera are treated more fully than the others, especially the so-called "larger Foraminifera." In all some 38 genera are treated. The organisms range from Eocene to recent.—*W. Berry.*

8186. **BIGOT, A. Sketch of the geology of Lower Normandy.** *Proc. Geol. Assoc.* [*London*] 41(4): 363-395. 2 maps, 3 pl., 4 fig. 1930.—The stratigraphical succession includes every geologic system above the Proterozoic. Fossils listed from the various formations indicate many rich faunal horizons.

8187. **BUSNEL, J. Découverte d'un gisement d'ampélites fossilifères dans la région de Médréac (Ille-et-Vilaine).** *Bull. Soc. Géol. et Minéral. Bretagne* 8(1/4): 112-114. 1927(1930).—Records the Silurian graptolites *Retiolites geinitzi, Monograptus,* and *Cyrtograptus* from this locality, and discusses their exact age.—*B. F. Howell.*

8188. **COLLIN, L. Étude géologique de l'île Longue. (Rade de Brest) [Brittany]** *Bull. Soc. Géol. et Minéral. Bretagne* 7(3/4): 216-224. Map. 1926(1929).—Lists the Devonian brachiopods, pelecypods, gastropods, cephalopods, trilobite, and ostracod found on this peninsula, and gives the age and distribution of their enclosing strata.—*B. F. Howell.*

8189. **CROOK, ALJA R. New plan illustrative of historical geology.** *Pan-Amer. Geol.* 53(2): 88-90. 1930.—Discusses the method employed in the Illinois State Mus. to illustrate the earth's history by use of the actual rocks and fossils in their proper sequence. The characteristic fossils of each geologic system are arranged with the dominant plants in one vertical column, other columns for coelenterates, echinoderms, mollusks, arthropods, and other invertebrates; followed by columns for fish, amphibians, reptiles, birds, and mammals. The arrangement shows the dominant types at the different times, the first appearance of the great zoological groups and the dates of maximum development.—*D. J. MacNeil.*

8190. **CURRIE, ETHEL D. The fossil fauna of the Samana Range and some neighbouring areas: Part II. The Albian Echinoidea.** *Mem. Geol. Surv. India, Palaeont. Indica* 15: 17-23. 1 pl. 1930.—Four forms (none specifically determined) are listed, with descriptions, figures, and taxonomic remarks.

8191. **DAVIES, L. M. The fossil fauna of the Samana Range and some neighbouring areas: Part I. An introductory note.** *Mem. Geol. Surv. India, Paleont. Indica* 15: 1-15. Map. 3 pl. 1930.—General description, structure, stratigraphy, including strata from Jurassic to possibly Eocene age, with mention of some of the fossils.

8192. **[DINGELSTEDT, N.] ДИНГЕЛЬШТЕДТ, Н. О находке нижне-силурийской фауны на Южном Урале близ Тирлянского завода. [Discovery of Lower Silurian fauna in the southern Urals, near the Tirlian factory.]** Известия Главного Геолого-Разведочного Управления. (*Bull. Geol. & Prospecting Service, USSR.* [*Leningrad*]) 49(1): 119-124. Map. 1930.—The limestone fauna consists chiefly of crinoids and stromatoporoids with a few brachiopods, gastropods, corals, and orthoceroids.

8193. **FENTON, CARROLL LANE. A message from paleontology.** *Pan-Amer. Geol.* 53(4): 241-254. 1930.—Stresses the importance of organic evolution as a doctrine calling for analysis and rigorous synthetic research, discussing several major treatises on evolution and their significance in studying the historical development of organisms. States that the field of the invertebrate paleontologist is as important in this problem as is that of the vertebrate paleontologist, because fossils belonging to the non-chordate phyla are more abundant and represent a greater variety of structures and a greater period of time.—*D. J. MacNeil.*

8194. **FRIEDBERG, W. Studja nad formacja mioceńska Polski. Cześć VI. [Miocene studies in Poland. VI.]** *Kosmos* [*Lwów*] 55(1/2): 357-381. 2 fig. 1930.—This part consists of several separate studies. The author opposes the view of Kautsky that the Miocene (Helvetian) sea of North Germany was connected with that of the Vienna Basin by way of Poland. Many of the 56 mollusks of supposedly northern origin, listed by Kautsky from the Vienna Basin, were known earlier than the Helvetian from Mediterranean strata. In migrating from the north, the mollusks would have appeared in the Miocene of Italy at a later stage than in the Vienna Basin, but this is not the case. Little remains of the collection in Zürich that formed the basis for the work of Fr. Dubois de Montpérreux, "Conchologie fossile . . . . du plateau wolhynie-podolien." On the basis of such fossils as *Hydrobia punctum, Ervilia pusilla, Amussium galicianum,* and *Serpula gregalis,* the fauna of the vicinity Sandomierz is Tortonian, not Sarmatian. A number of Miocene mollusks are listed from Chomentów and Daszawa.—*From author's summary.*

8195. **GREGORY, JOHN WALTER, and ETHEL DOBBIE CURRIE. The geological collection from the south central Sahara made by Mr. Francis R. Rodd. I. General geology.** *Quart. Jour. Geol. Soc.* 86(343): 399-403. 1 pl. 1930.—Notes are given on the formations represented. The fossil record shows that the Cretaceous equatorial sea of West Africa was connected with the European seas past Aïr and across the central Sahara.—*M. A. Fenton.*

8196. **[IÔRDANSKIĬ, N.] ИОРДАНСКИЙ, Н. О силурийских отложениях Северного Урала (рр. Вишера и Косьва). [Silurian deposits of the northern Urals (Vishera and Kos'va rivers).]** Известия Главного Геолого-Разведочного Управления. (*Bull. Geol. & Prospecting Service, U. S. S. R.* [*Leningrad*]) 49(1): 137-139. Map. 1930.—A varied fauna, not specifically determined, is reported.

8197. **JONES, OWEN T. Episodes in geological history of Bristol Channel region.** *Pan-Amer. Geol.* 54(4): 241-274. 1930.—States that a former extension of the Lias westward into the Gower peninsula is indicated by the finding of several oysters, allied to *Ostraea irregularis,* in stalactitic deposits in caves in the Carboniferous limestone at Mumbles.—*D. J. MacNeil.*

8198. **[KIRICHENKO, G.] КИРИЧЕНКО, Г. Верхнесилурийские отложения на западном склоне Урала в районе Михайловского завода. [Upper Silurian deposits on the western slope of the Urals in the region of the Mikhailovsk factory.]** Известия Главного Геолого-Разведочного Управления. (*Bull. Geol. & Prospecting Service, USSR.* [*Leningrad*]) 49(1): 130-135. 2 fig. 1930.—A few spp. are reported, chiefly brachiopods.

8199. **KOBAYASHI, TEIICHI. Cambrian and Ordovician faunas of South Korea and the bearing of the Tsinling-Keijô line on Ordovician palaeogeography.** *Proc. Imp. Acad.* [*Tokyo*] 6(10): 423-426. Map. 1930.—The Middle and Upper Cambrian faunas of South Korea are similar to those of North China and South Manchuria. A barrier seems to have been present during the Ordovician, for the Ordovician fauna of South Korea is closely related to the trilobite facies of Europe; while that of North Korea and South Manchuria shows an Arcto-American affinity. The Chikunsan (Ordovician) fauna includes 6 new species, named but not described.

8200. **LIEBUS, ADALBERT. Verzeichnis der geolog.-paläontologischen Literatur über das Gebiet von Böhmen, Mähren und Schlesien im Jahre 1929 mit Nachträgen aus früheren Jahren.** *Naturwiss. Zeitschr. Lotos* 78(2): 179-192. 1930.—About 286 titles.

8201. **[MASHKOVTSEV, S.] МАШКОВЦЕВ, С. К находке силурийской фауны по р. Лозьве на восточном склоне Северного Урала. [Discovery of Silurian**

fauna along the River Loz'va, on the eastern slope of the northern Urals.] Известия Главного Геолого-Разведочного Управления. (*Bull. Geol. & Prospecting Service, U. S. S. R.* [*Leningrad*]) 49(1): 139-143. 1930.—A number of forms are listed, chiefly brachiopods and crinoids.

8202. MAZERES, R. Note sur la faune des Faluns du Quiou, de Saint-Grégoire et de La Chaussairie. [Fauna of the marls of Quiou, of Saint-Grégoire and of La Chaussairie.] *Bull. Soc. Géol. et Minéral. Bretagne* 8 (1/4): 20-22. 1927(1930).—Lists the gastropods, pelecypods, and brachiopods found in these Miocene deposits, discusses their age, and notes that Dollfus recorded fishes, gastropods, pelecypods, brachiopods, bryozoans, corals, and a foraminiferan from these beds in 1920.—*B. F. Howell.*

8203. [MEFFERT, B. F.] МЕФФЕРТ, Б. Ф. Юрские отложения Имеретии. Область Окриба и бассейн Риона и Цхенис-цхали. (Предварительная заметка.) (The Jurassic deposits of Imèrètia, west Georgia. Preliminary note.] Известия Главного Геолого-Разведочного Управления. (*Bull. Geol. & Prospecting Service, USSR.* [*Leningrad*]) 49(1): 9-26. 3 maps. 1930.—A study of fossils collected from this region for the first time, and used as a basis for stratigraphic determinations, results in a different conception of the subdivisions of the Jurassic from that of Simonovitch and Fournier. The "schistes" of the porphyritic series yielding *Perisphinctes* sp. and *Parkinsonia sub-arietis*, and the "schistes verts" containing *Parkinsonia parkinsoni, P. p.* var. *pseudoferruginea, Perisphinctes* sp., *Harpoceras* cf. *opalinoides, Stephanoceras* cf. *rectelobatum, Lytoceras* cf. *polyhelictum*, and [the Pelecypoda] *Posidonomya daghestanica, P. buchi, P.* cf. *alpina, Aucella* sp., and others, are referred to the Bajocian; the sandstone and "schistes grisâtres et feuilletés," and the coal beds of Tkvibouli containing numerous fossil plants, to the Bathonian; and the red beds to the Tithonian.

8204. NEAVERSON, E. The Carboniferous rocks around Prestatyn, Dyserth, and Newmarket (Flintshire). *Proc. Liverpool Geol. Soc.* 15(3): 181-212. Map, 1 pl. 1930.—Numerous fossils previously known, together with additions from the author's collections, are listed from several localities.

8205. [POTULOVA, N.] ПОТУЛОВА, Н. Верхнесилурийские отложения р. Белой (Южный Урал). [Upper Silurian deposits of the river Belaîa (southern Ural).] Известия Главного Геолого-Разведочного Управления. (*Bull. Geol. & Prospecting Service, USSR.* [*Leningrad*]) 49(1): 124-127. Map. 1930.—Several genera of brachiopods and corals are reported.

8206. RITTMANN, A. Geologie der Insel Ischia [Italy]. *Zeitschr. Vulkanologie, Ergänzungsband* 6: i-viii and 1-265. 2 maps, 12 pl., 55 fig. 1930.—A table of previously found fossils, with their synonyms, is given, showing their matrix rock, locality, and relative abundance. It includes 28 spp. of Foraminifera, 4 of Anthozoa, 5 of Echinoidea, 2 of Vermes, 1 of Bryozoa, 93 of Lamellibranchiata, 4 of Scaphopoda, 161 of Gastropoda, 3 of Pteropoda, 1 of Crustacea, and 2 of plants from the volcanic ash and related deposits. The author considers their age to be Pleistocene.

8207. RUEDEMANN, RUDOLF. Geology of the Capital District (Albany, Cohoes, Troy and Schenectady quadrangles). *New York State Mus. Bull.* No. 285. 1-218. 2 maps, 39 pl., 40 fig. 1930.—A popular account, with some technical chapters. The accompanying geologic map stars localities which have furnished fossils but which now, for any reason, no longer afford collecting. A chapter on glacial geology by JOHN H. COOK is appended. There are ecological notes on the plant life of the region. About half the volume is concerned with the extremely rich and varied faunas of the 27 formations (Lower Cambrian, Ordovician, Silurian, and Devonian) that are present. The region has afforded unusually fine collecting, and many lists of fossils from classic localities are given. Bibliography of about 100 titles.

8208. SARDESON, FREDERICK W. Rational delimitation of species in paleontology. *Pan-Amer. Geol.* 54(4): 281-286. 1930.—Stresses the importance of naming new spp. carefully, not hurriedly, and lists several cases where confusion might, with care, have been avoided, e.g., with the brachiopod, *Gypidula occidentalis*, and the trilobite, *Dikelloce phalus minnesotense*. Commends patience in collecting, particularly in regions of rare fossils.—*D. J. MacNeil.*

8209. SAVAGE, T. E. The Devonian rocks of Kentucky. *Kentucky Geol. Surv.* 33: 1-170. Illus. 1930.—Fossils are listed by localities from the Jeffersonville, Sellersburg, Boyle, and New Albany formations as well as from the undifferentiated Devonian. 17 common forms from the Jeffersonville and 18 from the Sellersburg are figured.

8210. SCHUCHERT, CHARLES. Outlines of historical geology. 2nd ed., rewritten. iv+348p. Illus. John Wiley & Sons, Inc.: New York, 1931.—The discussions of plants and animals are brought together in the first part of the book; emphasis is placed on living forms; and change and evolution, as the keynote of all geologic chronology and paleontology, are stressed more than in the previous edition.

8211. SMITH, BERNARD, R. L. SHERLOCK, C. T. TRECHMAN, D. M. S. WATSON, H. C. VERSEY, and E. NEAVERSON. Validity of Permian as a system. *Pan-Amer. Geol.* 54(3): 179-186. 1930.—A symposium. Contains the arguments submitted by these authors for maintaining the name "Permian," both from a stratigraphical and paleontological viewpoint. Asserts that in general the fauna of the European Permian system is scanty and exceptional; in England it contains only one fossil common to the Carboniferous and none to the Triassic. States that, to judge from the amount of evolution that goes on in Amphibia and Reptilia, the Permian was of considerable length. Maintains that this system should be redefined by means of the marine invertebrate faunas, known chiefly from Sicily, India, and Texas; and points out that the fossil assemblages from these places are distinct from those of the Carboniferous and Triassic. Refers especially to a peculiar characteristic of the Permian ammonites, i.e., the frilling of the sutural lobes.—*D. J. MacNeil.*

8212. STERNBERG, C. M. Miocene gravels in southern Saskatchewan. *Trans. Roy. Soc. Canada, Sect. 4. Geol. Sci.* 24(1): 29-30. 1930.—Fragments of a fish, a tortoise, and 9 mammals (none fully determined) are reported from the Wood Mountain gravels.

8213. TEILHARD de CHARDIN, P. Quelques observations biogéographiques en Chine. *Compt. Rend. Som. Soc. Biogéogr.* No. 60. 94-96. 1930.—A comparison of the fossil faunas of the Tung Gur (Lower Pliocene) formation in the Gobi Desert and of the Nihowan beds (Upper Pliocene) in Chihli shows marked variations among the Mammalia but a striking continuity among the Mollusca. This indicates, from the Miocene to the Pliocene) in Chihli shows marked variations among fauna from the Gobi toward the south and toward the ocean. The author remarks on the development of Pleistocene and Recent rodents of the genus *Siphneus* from the ancestral *Prosiphneus* in the Pontian. Fossil mammals found in Chihli suggest a migration from Indo-Malaysia during the Upper Pliocene.

8214. WILLIAMS, M. Y., and W. S. DYER. Geology of southern Alberta and southeastern Saskatchewan. *Canada Dept. Mines, Geol. Surv. Mem.* 163. 160p. 5 pl. 1930.—This report includes numerous lists of fossils, as follows: plants from the Milk River, Foremost, Edmonton, St. Mary River, Estevan and Ravenscrag formations; mollusks from the Palowki shale (marine), Foremost and Pale beds (fresh- and brackish-water), Bearpaw (marine), Fox Hills (marine), Edmonton (fresh- and brackish-water), St. Mary River (fresh-water), Paskapoo (fresh-water), and Ravenscrag (fresh-water) formations; vertebrates from the Pale beds, Edmonton, St. Mary River, Paskapoo and Cypress Hills formations.

These rocks are of late Cretaceous and early Tertiary age, with the exception of the Cypress Hills beds, which are early Oligocene.—*L. S. Russell.*

8215. [ZENCHENKO, T.] ЗЕНЧЕНКО, Т. Силурийские отложения восточного склона Урала в районе Каменской дачи. [Silurian deposits of the eastern slope of the Urals in the region of the Kamen estate.] Известия Главного Геолого-Разведочного Управления. (*Bull. Geol. & Prospecting Service, USSR. [Leningrad]*) 49(1): 127-130. 1 fig. 1930.—The fauna includes several genera of trilobites, brachiopods, and corals.

EXPERIMENTAL ANATOMY AND REGENERATION

8216. BADILE, L. P. L'importanza della sede degli innesti del pancreas. [Importance of the location of pancreatic grafts.] *Riv. Patol. Sperim.* 5(4/5): 285-289. 9 fig. 1930.—Total pancreatic explantations were grafted in different locations (spleen, liver, omentum, subperitoneal and subcutaneous connective tissue, and submucous connective tissue of stomach). The grafts "took" partially only in the last location, where groups of well preserved Langerhans' cells were found after 105 days. —*M. Comel.*

8217. FREY, SIGURD. Zur Autotransplantation der Niere. *Bruns' Beitr. Klin. Chir.* 152(2): 299-304. 1931. —In 1 rabbit and 2 dogs, the right kidney was decapsulated and freed of all attachments but the renal vein and artery, and the ureter; several incisions 1-1.5 cm. deep were then made in the kidney and it was enveloped in peritoneum; 3 mos. later the vein and artery were removed. When the left kidney was removed 2 mos. thereafter, it was greatly hypertrophied. The right was felt as a small dense tumor in the peritoneum, to which it was adherent by connective tissue strands. The animals died in 3-4 days of uremia. Most of the right renal parenchyma had undergone connective tissue degeneration. There were capillary anastomoses with the renal parenchyma but none of the larger vessels.

8218. HARABATH, RUDOLF. Über die Heilung von Schnittwunden der Haut bei Fischen. *Virchow's Arch. Path. Anat. u. Physiol.* 268(3): 794-815. 7 fig. 1928.—Skin wounds in fish heal rapidly, but even simple cuts tend to become infected by fungus spores or bacteria. The epidermis regenerates though the formation of club cells is arrested. The basal membrane is formed from fibrin. No true regeneration of the cutis takes place. Spaces in the cutis become filled with new cicatricial tissue in the formation of which the subcutaneous and interstitial connective tissue alone take part. Mitoses were not observed in the regeneration of the epidermal and connective tissue cells.—*Z. Cooper.*

8219. HUGGINS, C. B. The formation of bone under the influence of epithelium of the urinary tract. *Arch. Surg.* 22(3): 377-408. 1 col. pl., 25 fig. 1931.—The abnormal occurrence of bone in the urinary tract of the dog, rabbit and man has been recognized but incompletely understood. In dogs transplantation of connective tissue to the urinary bladder with transplantation of the ureters to the skin (thus eliminating urine as a possible cause of ossification) resulted constantly in the formation of bone in the fascia transplant in the bladder. The bone forms in the connective tissue underneath the epithelium only in the transplanted fascia, never in the muscular wall of the bladder. Transplantation of urinary bladder mucosa to the fascial sheets, subcutaneous tissue and striated muscle of the trunk and extremities results in the formation of an epithelium-lined cyst containing fluid with a high P and Ca content and a low pH, that is partially surrounded by bone. The bone is in the connective tissue, not in direct contact with the mucous membrane. It is true membrane bone with nutrient canals and hemopoietic marrow. This bone occurs in the dog constantly after the 18th day, provided the transplant survives. The kidney, spleen, peritoneum and bladder muscle wall do not ossify when exposed to the influence of the growing urinary bladder epithelium. The gastric, jejunal, gall bladder, and colic epithelia do not form bone in transplants to the parietal fascia. The ureteral and renal pelvis epithelia act in the same way as the bladder epithelium. Transplantation of the bladder epithelium to the parietal fascias in the rabbit or albino rat does not result in the deposition of bone.—*C. B. Huggins.*

8220. JOHNSON, ADELAIDE, and VICTOR JOHNSON. Attempted autotransplantation of the adrenal cortex. *Amer. Jour. Physiol.* 97(2): 392-395. 1931.—The authors were uniformly unsuccessful in attempts to autotransplant the adrenal cortex of 46 dogs to the thyroid, omentum, testis, kidney and liver.—*Authors' conclusions.*

8221. KOZELKA, A. W. Integumental grafting in the domestic fowl. *Jour. Heredity* 20(1): 2-14. 10 fig. 1929. —Secondary sexual structures from day-old chicks were transplanted onto various parts of the body of the same or of other individuals under 3 days of age. Autoplastic feather tissues developed normally on any part of body. Comb appeared to grow best in normal position, being usually somewhat smaller on other parts of the body. While normal symmetry was maintained in most cases, some of the grafted combs varied in shape from an irregular mass to a rosette. No nerves grew into the grafted portions. Normal differentiation of autoplastic ♀ spur took place only on scaly tissue of the shank, remaining partially or wholly juvenile elsewhere. In ♂♂ spur developed characteristically on any part of body, except in 1 case where it remained juvenile. Ovary appeared to have no inhibiting effect upon the development of ♂ spur. Of 13 homoplastic grafts with ♀♀ as recipients, 7 spurs from ♂ donors developed into characteristic ♂ spurs, while those from ♀♀ behaved like autoplastic spurs. This seems to indicate that there is a genetic difference between the spurs of the 2 sexes. The percentage of initial "takes" among homoplastic grafts is high but of the positive grafts, 74% are subsequently resorbed when unrelated birds are used. The percentage of resorption was reduced 20% by use of half and full brothers and sisters. Resorption takes place either by rapid disintegration, or by gradual replacement of the grafted tissue extending over several weeks. Usually

complete resorption takes place before the end of 2 mos. No replacement was noticed among the autografts.—*Author's abstract.*

8222. KROHN, ERNA. Fütterungsversuche an Tritonen. III. Die Veränderung der Kopfform des Teichmolches (M. vulgaris [taeniata]) infolge Muschelfleischfütterung. *Zeitschr. Wiss. Biol. Abt. D. Roux' Arch. Entwicklungsmech. Organ.* 121(4): 545-597. 19 fig. 1930.—Descendants of 2 pairs of salamanders, 356 and 162 larvae respectively, were divided into groups of 20 each, and at first 10 of each group (designated M) were fed on flesh of mussels, and the other 10 (designated Co) were fed on plankton; later fewer Co animals were used. The author confirms the earlier findings of Klatt that exclusive feeding with mussel flesh produces morphologic changes in the head of *M. vulgaris*. The head of the M animal was shorter, broader and higher, frequently with a relatively shorter lower jaw than that of the Co animals. The M animals develop a throat-sac; the tongue lies in the bottom of the mouth, and the eyes frequently project. These morphologic differences of the M head are caused by changes of its structures. Skull capacity and masticatory muscles are markedly increased, nasal cavities, ear vesicles, and intermaxillary glands markedly decreased. The increased skull capacity of the M salamander is necessitated by the great enlargement of the ventricles and of the brain, which again is apparently caused by an increase in ventricular fluid; an increase in fluids is also observed in other regions of the body. The hypophysis is much increased by M feeding; the thyroid is of normal size.—*From author's summary (transl.).*

8223. MOROSOW, B. D. Weitere Explantationsversuche an getrockneten Geweben der Wirbeltiere (Gehirn, Herz, Milz, Testikel und Haut). *Arch. Exp. Zellforsch. Bes. Gewebezücht.* (*Explantation*) 10(2): 157-173. 4 fig. 1930.—Pieces of various tissues (spleen of 6 mos. *Rana temporaria* and fullgrown axolotl; testis, heart, and ciliated epithelium of oesophagus and tongue of young frog; skin of young frog and axolotl; brain of 1½-2 mos. old axolotl; heart of fullgrown axolotl; and cerebrum and heart of 7-9 day old chick embryos) were dried for 30 min.-3½ hrs. over H_2SO_4, then softened 1-3 hrs. in Ringers solution. 325 cultures were made of 1-3mm. fragments in plasma and embryonal serum. Growth occurred even after the following loss of wt.: frog spleen 67%, frog testis 75%, frog skin 43.2%, axolotl skin 44%, brain of young axolotl 80%, brain of chick embryo 90.7%, ciliated epithelium 65%. Frog and axolotl hearts placed in a glucose-Ringer hypertonic solution of 1 *M*, 1.5 *M*, and 2 *M* for 3 hrs., 2 hrs., and 44 min. respectively, and axolotl spleens of 1.5 *M* solution for 55 min., still grew in culture. Axolotl hearts and chick embryo hearts and brains were dried and kept at +4°C. in closed vessels. Axolotl hearts so kept for 100 hrs., chick embryo hearts for not more than 24 hrs., chick embryo brain (dried with a loss of wt. up to 76%) for 144 hrs. still grew. These experiments indicate the stability of biocolloids and the great resistance of the living cell to loss of water.

8224. PINKUS, HERMANN. Untersuchungen über das Verhalten des Hühnerpankreas in der Gewebezüchtung. *Arch. Exp. Zellforsch. Bes. Gewebezücht.* (*Explantation.*) 10(1): 1-42. 16 fig. 1930.—Pancreas tissue from 8-12 day old chick embryos and from chicks a few hrs. to several weeks old (largely day old unfed chicks) was grown by Fischer's cover glass method, using a mixture of heparine-chicken blood plasma and chick embryo extract. All cultures were transplanted every 3 days. Growth proceeded from the differentiated cells of the original material. The epithelium usually grew in the form of coherent bands and membranes, the cells of the excretory ducts and of the exocrine glands participating. In only 1 instance were cells from the islands of Langerhans observed. After the first few days, gland cells and duct cells could not be differentiated. The secretory granules disappeared in a few weeks, by sloughing of the portions of the cells containing them or by their own alteration and disappearance. Very few granules were formed in the cultures. Cell migration, cell enlargement, and cell multiplication contributed to the growth areola. Epithelial movement did not differ from that of other body cells. Cells multiplied by mitotic division; amitotic nuclear division appeared to lead only to multinuclear cells. The epithelial cells in the later stages were characterized by the capacity for fibrinolysis and the ability to form compact, gland-like structures. Pure cultures were obtained; the oldest lived 40 days. Under some conditions epithelial cells appeared isolated and ameboid. They were able to phagocytose, under some conditions taking the form of epithelial macrophages.

8225. PONSE, K. La notion de territoire et les excroissances digitales du crapaud. *Zeitschr. Wiss. Biol. Abt. D. Roux' Arch. Entwicklungsmech. Organ.* 121(4): 755-769. 13 fig. 1930.—E. Guyénot stated that "the adult organism is a mosaic of cellular territories with specific reactions." Testing this, 21 experiments on 13 adult ♂ toads (*Bufo vulgaris*) were performed, in which the digital or copulatory pads were removed from their normal positions, replaced by smooth skin from other parts of the body, and transplanted to the place from which the smooth skin had been removed. Each fragment of skin preserved its own characteristics in its new location. Observations are also reported on natural anomalies or mutilations of 13 toads and 1 artificial amputation on *Rana esculenta*, which indicate that abnormal position of the digital pads corresponds to skeletal abnormalities. General conclusions are that: the testicular hormone is incapable of calling forth a particular morphologic response (in this case, the development of digital pads) except where it finds a "specific receptor"; these specific receptors are localized in specific "territories"; after castration the warty condition diminishes, but, given the presence of the sexual glands, the location of the excrescences is determined by the local receptors. When the animal regenerates an amputed limb, it also regenerates, more or less completely, the "territories" containing the determining receptors.

8226. QUASTLER, H., und H. WEINGARTEN. Können Fische die Riechschleimhaut regenerieren? *Zeitschr. Wiss. Biol. Abt. D, Roux' Arch. Entwicklungsmech. Organ.* 122(4): 763-769. 1930.—The authors having cauterized the olfactory area in *Tinca vulgaris, Carassius carassius, Cobitis fossilis,* and *C. taenia,* believe it improbable and unproven that the primary sensory cells of the olfactory mucosa can be regenerated from general epithelium.

8227. THOMAS, J. W. TUDOR. On the return of sensitiveness in corneal grafts in rabbits. *Proc. Roy. Soc. [London] B* 108(757): 301-305. 1931.—In 29 cases of completely united corneal grafts in rabbits, 5 remained clear and insensitive, 1 had a central clear area and remained insensitive, and 21 out of 23 opaque grafts became vascularized and sensitive. Analysis of these experiments seems to show a clear correlation between the vascularization of a corneal graft and the invasion of it by the afferent nerve fibers upon which depends the return of sensitivity.—*Author's summary.*

GROSS ANATOMY (EXCEPT PRIMATES)

8228. AMANO, KAGEYAS W. The labyrinth of Bufo vulgaris japonicus larva. Especially, upon the morphologic study of the perilymphatic space, in connection with the membranous labyrinth and auditory capsule. *Jour. Morph. & Physiol.* 51(1): 207-242. 10 pl. 1931.—A morphologic study of the labyrinth (in a 45 day old larva, 24 mm. total length), especially on the perilymphatic space with its physiologic aspect. The perilymphatic space starts its development with the chondrification of the auditory capsule, and is completed by the end of the first third of metamorphosis. The author divides the whole spatium into 2 parts: the ductus perilymphaticus et diverticula and the pars spongiosa spati perilymphatici. The ductus perilymphaticus et diverticula may play an important rôle in carrying out the functions of both equilibrium and audition. The pars

spongiosa serves not only to fasten the membranous labyrinth to the capsular wall, but acts a a safeguard for the functions of both the membranous labyrinth and the ductus perilymphaticus et diverticula. The ductus system may have more important physiologic relations than does the membranous labyrinth in connection with the cranial cavity and spinal cord, as to change of pressure, transmission of vibrations, osmosis of fluids, etc.—*Author (courtesy Wistar Bibl. Serv.).*

8229. **BARBOSA SUEIRO, M. B. Annotations anatomiques. V. Note sur l'hyperextension et l'hypo-extension du coude chez d'autres mammifères que l'homme.** *Arquivo Anat. e Antrop.* [*Lisboa*] 12(1): 189-193. 1928.—The author examined 85 skeletons of mammals (monotremes, marsupials, edentates, sirenians, perissodactyls, artiodactyls, hyracidae, proboscidae, carnivores, pinnipeds, rodents, insectivores, prosimiidae, anthropoids) for the index-angle formed by the axis of the ulna and the extended vector (flèche prolongée) of the sigmoid notch of the bone. Hyperextension is extremely exceptional; the author noted it only in the elephant, orang, and chimpanzee; all others showed hypo-extension. There is not the slightest connection between hyperextension of the fore-arm and the existence of the olecranon perforation. The author found several animals with both olecranon perforation and hypo-extension; only 2 (orang and chimpanzee) showed both perforation and hyperextension.—*M. B. Barbosa Sueiro (transl. by E. W. Count).*

8230. **KARBOWSKI, B. Vergleichend anatomische Studien über den Aquaeductus cochleae und über seine Beziehungen zum Subarachnoidealraum des Gehirns.** *Monatsschr. Ohrenheilk. u. Laryngo-Rhinol.* 64(6): 687-715. 1 pl. (col.), 25 fig. 1930.—In guinea pig, rabbit, and dog there is a free communication between the perilymphatic space in the inner ear and the subarachnoidal space. An abundant exchange of fluid is possible between the subarachnoidal space and the ear in guinea pigs and rabbits. In all 3 animals an aquaeductus cochleae membranaceus (A.C.M.) is present which can be lifted directly from the arachnoidal sheath of the glossopharyngeal nerve or from its surrounding tissue and which continues into the bony aquaeductus cochleae (A.C.) lined with dura. In most cases the A.C.M. is a reticular, permeable strand of connective tissue; but often in guinea pigs and rabbits it is a hollow tube. In most cases a subdural space is present, but in some cases, the A.C.M. is intimately adherent to the dura. The anatomical relations in man are similar to those in animals in that the communication between the subarachnoidal space and the perilymphatic space of the inner ear is not equally wide and equally permeable in all cases. In some cases the canal is partially or entirely filled with a thick connective tissue strand which obliterates the lumen; often there is a free, wide, patent canal. In man free routes lead from the subarachnoidal space of the brain into the medullary space of the bone by means of perivascular, arachnoidal sheaths. An open connection is likewise possible between the subarachnoidal space of the brain and the subepithelial tissue of the paries jugularis, by interposition of the canal for the tympanic nerve.—*Author's summary (transl.).*

8231. **KLAAUW, C. J. van der. La région tympanique du crâne du Megatherium.** *Tijdschr. Nederl. Dierk. Ver.* 2(2): 77-82. 1930.—Additional remarks on this region in *Megatherium* with description of tympanic, entotympanic and neighboring skeletal elements. The entotympanic functions not only as a skeletal covering of the ventral wall of the tympanic cavity but it also, perhaps, affords surface attachment for muscles.—*C. J. van der Klaauw.*

8232. **KLAAUW, C. J. van der. La région tympanique du crâne du Scelidotherium.** *Tijdschr. Nederl. Dierk. Ver.* 2(2): 83-87. 1930.—Additional remarks on this region in *S. leptocephalum* and description of neighboring skeletal elements, the so-called ossiculum accessorium malleoli and the entotympanic (generic characters given which differ from those in *Glossotherium,* and in *Pseudolestodon* and *Lestodon*).—*C. J. van der Klaauw.*

8233. **[LIŪBITSKAĬA, A. I.]** ЛЮБИЦКАЯ, А. И. Изменение положения и функции полукружных каналов камбал как органа равновесия, в связи с асимметрией их тела. **[Change in position and functions of the semicircular canals of flounders as organs of equilibrium in connection with the asymmetry of their bodies.]** [German summary.] Известия Научного Института имени П. Ф. Лесгафта. (*Bull. Inst. Sci. Lesshaft*) 16(1/2): 19-53. 1 pl., 15 fig. 1930.—Observations were made on *Pleuronectes flesus, P. platessa, Rombus maeoticus,* and *Solea nasuta.* The horizontal semicircular canals of both labyrinths lie in a verticle position when the flounders are turned 90°, i.e., to a position normal for symmetrical fishes. The posterior vertical canal lies in a frontal vertical position at an angle of 90° to the horizontal canal. In the flounder, the angle between the horizontal canal and the parasphenoid is greater on the blind (under) side than on the other, whole in symmetrical fishes these angles are equal. In most cases the otolith of the lower labyrinth weighed more than that of the upper, while in symmetrical fishes the weight of the two otoliths is equal. Complete removal of the labyrinth from either side resulted in various movements, particularly in rotation along the horizontal axis. After removal of the labyrinth from the upper side, normal swimming movements were resumed after 48-60 hrs., while after removal of the labyrinth from the lower side normal swimming movements were resumed after 5-6 hrs. Removal of the labyrinths from both sides resulted in chaotic movements like those of symmetrical fishes similarly operated. Such flounders survived up to 34 hrs. without resuming normal swimming movements. Ligation of the vertical semicircular canals and simultaneous cutting of the nerves supplying the ampullae resulted in the absence of compensatory movements in the horizontal or vertical planes. A similar operation on the horizontal canals resulted in the absence of compensatory movements in the sagittal plane. Ligation of all the semicircular canals and the cutting of the nerves supplying the ampullae gave results similar to those obtained by a complete removal of the labyrinths. Electrical and mechanical stimulation of the ampulla of the anterior vertical canal of the upper side caused rotatory movements of the eye on the same side only. A similar stimulation of the blind (lower) side resulted in similar eye movements of this side only. Stimulation on both sides simultaneously resulted in similar rotatory movements of both eyes. Similar experiments on the posterior vertical canal on either side or both sides resulted in most cases in no response. Similar stimulation of the horizontal canal of the eye-side resulted in eye movements of this side; stimulation on the blind side gave no consistent results. Thermal stimulation of the ampullae of the canals gave no response of the eye.—*S. A. Corson.*

8234. **MOSKOFF, M. Eine Besonderheit der V. sperm. interna beim Hengst.** *Anat. Anz.* 71(21/22): 475-477. 1931.—In grown stallions shortly beyond the branching of the internal spermatic vein from the caudal vena cava, a branch passed directly along the plica vasculosa toward the internal inguinal ring; from it a few fine branches passed to the plica pampiniformis and to the lateral surface of the testis entering the epididymis and, mainly, the testis. In fetuses this branch, being much larger than the internal spermatic vein, apparently was the principal vessel. The branch was also larger in a left sided cryptorchid, and in several geldings when the plicae vasculosae had withdrawn into the abdominal cavity after castration. The flow of blood from the testis in the fetus seems to differ from that in the adult.

8235. **MÜLLER, RICHARD JOHANNES. Die Mechanik der syndactylen Zehen von Macropus und anderen Beuteltieren und ihre Verwendung als Putzorgan.** *Zeitschr. Wiss. Biol. Abt. A. Morph. u. Ökol. Tiere* 17(1/2): 154-218. map, 94 fig. 1930.—The fused 2nd and 3rd toes of the Macropodidae are not rudimentary or degenerate

organs, but are especially developed and adapted for the function of cleaning or combing. The leg and foot, with the exception of these toes, are arranged for a springing type of locomotion. That is, all joints below the knee are fixed so that they are immovable laterally; the 4th toe, much enlarged and rendered inelastic, forms with the calcaneus and the shank bone a much extended lever arm; and the 5th toe is spread laterally as a balancing organ. The 2nd and 3rd toes, on the other hand, are small, fused, and displaced somewhat laterally, and their joints are so arranged as to give motion only in latero-medial directions. The muscles, like the bones, are arranged in 2 separate systems, one concerned in the springing locomotion, the other in the lateral and medial flexion of the syndactyl toes. In the syndactyl elements the skin and the connective tissues are well innervated, the claws are specially remodeled, and in fact all the structures indicate a high type of developmental adaptation to the function of scratching or cleaning. These conclusions drawn from detailed morphological study of the feet of the Macropodidae of various species are supported by extensive comparative studies on the feet of other marsupials. The author has tried to arrange the marsupials in a phylogenetic series to show the evolution of syndactylia in the toes, taking into account both syndactyl and didactyl forms and both Polyprotodontia and Diprotodontia. He has also considered the parasites found on the various forms. Finally, the author includes some suggestions as to the ecological and geographical conditions surrounding the origin of syndactylia.—*F. W. Appel.*

8236. POHL, LOTHAR. Zur Morphologie der männlichen Kopulationsorgane der Säugetiere; insbesondere der Versuch einer vergleichend-anatomischen Studie über den Penis der Primaten, einschliesslich der Menschen. *Zeitschr. Ges. Anat. 1, Abt. Zeitschr. Anat. u. Entwicklungsgesch.* 86(1/2): 71-119. 3 pl., 8 fig. 1928.—The morphology of the mammalian penis and the fundamental types are discussed. Three types are recognized: (1) A form whose pars libera penis consists of a corpus penis and a pars intrapreputialis, composed only of a corpus fibrosum and a corpus spongiosum. This type is found in Monotremata, Edentata, Marsupialia, Cetacea, Ungulata, Rodentia, Carnivora, Insectivora, Chiroptera, and Primates. (2) A type similar to the first but with a terminal corpus cavernosum on the pars intrapreputialis, forming the caput penis. The form of the pars intrapreputialis varies greatly in this type and frequently presents a bony structure in the corpus fibrosum which rarely occurs in the first type. This type is found in the groups noted under type 1 (excepting Cetacea) and also in Sirenia, Pinnipedia, and Hominidae. (3) A type which includes a few cases which can not be classed with either of the first two because of morphological peculiarities that indicate secondary changes. It is found in some Insectivora and Chiroptera, and in the Canidae,—forms without a true preputium and those with a secondary terminal section produced by great vascularization of the preputium, and with a secondary preputial cavity. The second part of the paper deals with the penis of primates including man, and specific description is given of the organ in: *Lemur varius, Nycticebus tardigradus, Galago monteiroi, Ateles sp.?, Lagothrix lagotrica, Alouatta ursina, Hapale jacchus, Cebus capucinus, C. robustus, C. flavescens, Oedipomidas oedipus, Brachyteles arachnoides, Homo sapiens, Simia satyrus, Siamanga syndactylus, Hylobates leuciscus, Anthropopithecus troglodytes, Lophopithecus melalophus, Presbypithecus cephalopterus, Nasalis larvatus, Rhinosticticus cephas, Cercopithecus sabaeus, Erythrocebus pyrrhonotus, Mona mona, M. neglectus, Cercocebus aethiops, Zati sinicus, Z. cynomolgus, Nemestrinus nemestrinus, Macacus rhesus, M. heckii, Cynopithecus niger, Choeropithecus sphinx, C. porcarius, Hamadryas hamadryas.* The distribution of the various types of penis, the variations of the corpus fibrosum, and the various forms of the organ found in the different groups are discussed. Two general types are found in the primates and the conception of a diphyletic origin is not excluded. The os penis is characteristic of individual species of primates but the external form of the penis has no phylogenetic value. The corpus fibrosum exhibits a fibrous, a connective tissue, and a bony structure in different forms and since these stages also appear in the ontogeny it may have some phylogenetic significance. With reference to the structure and development of the penis, man appears to represent a connecting link between certain platyrrhine and catarrhine apes. Occasional ossifications in the penis of man can be thought of as the result of a developmental growth tendency extending beyond the usual end stage. Neither the form nor the structure of the penis of the chimpanzee can be correlated with the organ of the rest of the primates. Among the anthropoids, the penis appears to be the most primitive in the chimpanzee and man. The organ in man is closest to that of the Indrisinae of the Madagascar Prosimiae.—*H. F. Nachtrieb.*

8237. REESE, A. M. The ductless glands of Alligator mississippiensis. *Smithsonian Misc. Coll.* 82(16): 1-14. 3 pl. 1931.—The gross and microscopic structures of the following organs of *A. mississippiensis* are described: adrenal, thyroid, parathyroid, post-branchial body, thymus, hypophysis and spleen.—*A. M. Reese.*

8238. SMIRNOWSKY, B. N. Zur Morphologie der respiratorischen Muskulatur der Lacertilien. [Morphology of the respiratory muscles of the Lacertilia.] *Anat. Anz.* 70(1/4): 58-77. 8 fig. 1930.—The arrangement of the respiratory muscles in the following species were studied: Geckonidae—*Platydactylus* sp. and *Tarentola mauritanica;* Agamidae—*Agama sanguinolenta, A. stellio, Phrynocephalus mystaceus;* Iguanidae—*Iguana tuberculata;* Varanidae—*Varanus griseus;* Lacertidae—*Lacerta ocellata, L. agilis;* Scincidae—*Eumeces schneideri, Mabuja septemtaeniata.* In addition *Ameiva* of the Tejidae was partially studied. The M. obliquus externus varies in different Lacertilia: thus both layers (superficialis and profundus) are present in the Lacertidae and Iguanidae studied, the Scincidae have a completely developed superficialis and a subnormally developed profundus; in the Varanidae only the superficialis is present and in the Agamidae and Geckonidae studied only the profundus. The M. intercostalis externus can be either brevis or longus; in *Lacerta agilis* it forms the "mm. scalares externi." *Varanus* differs from all Lacertilia studied in the presence of the "Mm. serratoidei," analogous to the M. serratus dors. of mammals. —*W. Bloom.*

8239. VALLOIS, H. V. Nouvelles preuves de la non-dualité du prémaxillaire chez l'homme. *Ann. Anat. Path. et Anat. Normale Méd.-Chir.* 7(6): 748-753. 2 fig. 1930. —Leuckart inferred from a suture in the palatine portion of the premaxillary (intermaxillary) bone in certain fetuses that the bone was formed by the amalgamation of 2 pieces, internal and external, which Albrecht 30 yrs. later named endognathion and mesognathion. The author discusses the evidence from *Ornithorhynchus* and higher mammals, and concludes that all the evidence from comparative anatomy, embryology and teratology indicates that the premaxillary in man and other placental mammals is essentially a single bone.

8240. VILLIERS, C. G. S. de. Some features of the cranial anatomy of Hemisus marmoratus. *Anat. Anz.* 71(14/16): 305-331. 14 fig. 1931.—The skull is so specialized that its structure gives no indications as to its affinities. Some of the prominent "specializations" are the absence of the inferior prenasal cartilage, plica isthmi, nasolacrimal duct, quadrato-maxillary, vomers, palatines, cartilaginous taeniae, plectral apparatus, annulus tympanicus, processus basalis, middle ear and Eustachian tubes, and the "basicranial" portion of the chondrocranium. More positive features are: (1) presence of a nasal plug with its component solar osseous support containing a system of canals with erectile walls; (2) fusion of the nasals and the ethmoid portion of the os-en-ceinture (sphenethmoid); (3) almost total ossification of the mentomandibular, nasal capsule, sphenoidal

portion of the os-en-ceinture and otic capsule; (4) fusion of the pterygoid and paraquadrate, etc. No conclusive evidence is offered with regard to the ranid or brevicipitid affinities of *Hemisus*. "*Hemisus* occupies an isolated position within the Firmisternia and is to be looked upon as a case of extreme adaptation to a terrestrial, fossorial mode of life."—*P. L. Risley.*

8241. **ZIMMERMANN, A. Beiträge zur vergleichenden Anatomie des Kaninchenherzens.** *Állattani Közlemények [Budapest]* 27 (3/4) : 181-191. 1930.—With the assistance of F. Lootz, the author compared the rabbit's heart (*Oryctolagus cuniculus* L.) with that of the wild hare (*Lepus europaeus* Pall) to determine the influence of domestication and captivity on its size, weight, form and structure. Hearts of 10 rabbits of different ages and breeds and hearts of 10 hares of various sizes were used. The heart of the rabbit is distinguished from that of the hare principally in size and weight relationship; this peculiarity can be considered as the result of domestication. Remaining differences are of less significance.—*D. Fehér (transl. by M. Dresbach).*

HEMATOLOGY (INCL. RETICULO-ENDOTHELIUM)

8242. **ARRAK, A. Über die Identität der vitalgefärbten und polychromatischen Erythrocyten, zugleich ein Beitrag zur Frage der Alterspolychromasie.** *Zeitschr. Klin. Med.* 106 (5/6) : 640-650. 1927.—The number of polychromatophilic erythrocytes in blood averages 1.5 less than that of the vitally stained erythrocytes. In regenerating blood, there is a parallel increase in the number of vitally stained and polychromatophilic erythrocytes. The findings indicate that the vitally stainable substance in erythrocytes is practically indentical with the polychromatophilic substance, and that the former is a precipitate of the diffusely distributed basophilic substance. When blood is kept at incubator, room, or icebox temp. polychromatophilia does not develop.—*W. Bloom.*

8244. **BRATIANO, SERBAN, et ANTOINE LLOMBART. Nouvelles recherches sur l'histophysiologie du système réticulo-endothélial.** *Ann. Anat. Path. et Anat. Normale Méd.-Chir.* 7 (1) : 69-85. 1930.—The experiments (chiefly intravenous injections of India ink and lithium carmine) were made on several species of vertebrates (frogs, pigeons, palmipeds, dogs, cats, guinea-pigs and rabbits). The authors conclude that there are both a morphologically defined reticulo-endothelial system (reticulo-endothelial elements of the spleen, liver, bone-marrow and lymph nodes) and local reticulo-endothelial systems, of which some (lung, choroid plexus) are likewise morphologically defined, while others (limited skin-subcutaneous regions) arise out of physiologic or pathologic necessities. The specific functions of reticulo-endothelial systems acting as a group are the fixation and stabilization of colloids by intracellular storage, without morphologic or biologic change of cells or of their cellular territory. The experimental introduction of colloids demonstrates functions which are exercised under normal conditions. Blockage is a fact; it may be produced experimentally or physiologically, by products of cellular metabolism. Blockage of the cellular unit may be complete, but blockage of the entire reticulo-endothelial system is probably incompatible with normal life of the animal.

8245. **BRÜDA, B. E., und W. KREINER. Homoioplastik und Reticuloendothel.** *Deutsche Zeitschr. Chir.* 222 (3/5) : 285-301. 9 fig. 1929.—The time of survival of glands of internal secretion when transplanted varies even under similar conditions. In 30% of rats and rabbits subjected to x-ray, transplants survived for a longer period than in normal controls. This is attributed to a decreased functional activity of the reticulo-endothelial system in animals subjected to x-ray. In contrast to these results no effect could be demonstrated in the healing of homoplastic skin grafts after exposure to x-ray, injection of electro-negative colloids, and splenectomy.—*G. L. Muller.*

8246. **CAMPANACCI, D. Particolari elementi cellulari a granulazione basofila nel ratto e nel topo. [Certain cellular elements with basophil granulations in the rat and the mouse.]** *Ateneo Parmense* 2 (1) : 1-5. 1930.—These formations were found regularly in the medulla of the femur of the white mouse and rat; less regularly in the marrow of other bones; occasionally in the heart's blood and in the veins of the abdominal organs; never in the peripheral blood. In fresh preparations the cellular structure was evident, the protoplasm being crowded with granules as in eosinophil cells; the granulations were yellowish and not, as in eosinophils, refractive. In a diluted solution of methylene blue, fuchsin, gentian violet, etc., the small rounded nucleus stained before the granules. With a very dilute solution of Nile blue sulphate, the granules pass from bright violet to dark violet and finally dark blue; with a dilute solution of brilliant cresyl violet, from orange red to dark red and finally purplish red. The author believes that the granules do not represent granulations of primarily cellular material but are probably material taken up by macrophagic elements.

8247. **CLASING, CARL. Über den Abbau der Bluthistiocyten.** *Virchow's Arch. Path. Anat. u. Physiol.* 277 (1) : 143-158. 5 fig. 1930.—About 20 white mice received intravenous injection of India ink or cinnabar, and were killed at various intervals afterward. The ink was taken up by the endothelial cells of the liver, spleen, lungs, bone-marrow, suprarenals and intestine, which, laden with ink, then become detached wandering histocytes, and finally underwent dissolution in the liver and spleen. In the liver these histocytes became fixed, agglomerated, and finally decomposed in the capillaries of the edges of the lobules. The indigestible burden of ink or cinnabar remained in great lumps. In the spleen histocytes were taken up by the reticular cells, and in part destroyed in the meshes of the reticulum, where also lumps of ink remained. The lungs freed themselves very rapidly from ink-encumbered cells, and took no part in the destruction of the histocytes. The occasional lumps in the pulmonary capillaries which suggest the destruction of histocytes are rather to be regarded as emboli from the hepatic capillaries.

8248. **DELBET, PIERRE, et DAN BERCEANO. Le diacrisocyte.** *Ann. Anat. Path. et Anat. Normale Méd.-Chir.* 7 (8) : 909-918. 1 pl. (col.), 4 fig. 1930.—In the spleen and, to some extent, the bone-marrow of guinea-pigs vaccinated with "propidon" the authors found a leucocyte of a hitherto unknown description—a large ovoid cell with nucleus shaped roughly like a thick crescent. With Giemsa stain, the cytoplasm appeared to contain numerous granules, but later preparations with very rapid fixation and other stains indicated that the granular appearance was an artefact. The cell seemed to contain a ball shaped mass of albuminous material. The authors consider this inclusion body to be a secretion of a holocrine cell. They call this cell a "diacrisocyte," i.e., secretion cell.

8249. **FERRARI, RODOLFO. Sulla funzione fagocitaria dei megaloblasti nello sviluppo ontogenetico della rana. [Phagocytic function of megaloblasts in ontogenesis of the frog.]** *Boll. Soc. Ital. Biol. Sperim.* 5 (6) : 840-842. 1930.—In embryonic blood of the frog, histioid cells are present which show megaloblastic evolution and phagocytic activity. This activity is a nutritive one for the primitive migratory blood cell. It is shown not only by the hemohistioblastic cells, but also by the differentiated cells of the erythrocytic series.—*M. Comel.*

8250. **FUJIMOTO, TAKEHEI. Über die Verteilung von den ferrophilen sowie karminophilen Bindegewebszellen in den Lungen und in dem Verdauungstraktus**

beim Kaninchen. [In Japanese, with German summary.] *Mitted. Med. Ges. Tokio* 43(5): 721-730. 1 pl. 1929.—In adult rabbits 4% lithium carmine was injected intravenously and 4% "Eisensomatose," intraperitoneally. In others 4% lithium carmine was injected intraperitoneally and 4% "Eisensomatose" intravenously. The lungs of 2 of these showed large numbers of cells in the bronchial wall and adventitia which were filled with carmine granules. A few megakaryocytes were present. In localized areas of the cardiac and pyloric stomach of all rabbits were many enlarged elliptical connective tissue cells filled with carmine granules. Only in certain ones could elliptical connective tissue cells full of iron particles be found in the mucosa of the pylorus. The wall of the small intestine contained carmine-filled cells only in the basal part of the mucosa. In the caecum of many were large, free, iron-bearing connective tissue cells. These cells contained no carmine granules. In the large intestine, including the sigmoid flexure, there were large numbers of carmine-filled cells.—*H. W. Kaan.*

8251. **GELDEREN, CHR. van. Betrachtungen über die Entwicklung des Blutbildes des Menschen und über seine vergleichende Anatomie.** *Zeitschr. Ges. Anat. Abt. 1, Zeitschr. Anat. u. Entwicklungsgesch.* 87(5/6): 758-765. 1928.—The places of blood formation in man are in chronological order: embryonic structures, liver, spleen, bone-marrow. The series begins with those organs that are the blood-forming organs in the adult lower vertebrates. In various mammals the liver and spleen are the last to take part in blood-production. As early as the 4th fetal month non-nucleated erythrocytes predominate in the circulation, but some erythroblasts are present until after birth. As a result of the birth-noxa their number is temporarily increased. The white blood-picture of the fetus and young child is lymphocytic, as in the majority of mature mammals. The leucocytic blood-picture accordingly is a late ontogenetic and phylogenetic acquisition. A birth leucocytosis interrupts (without a phyletic analogue) the developmental lymphocytic continuity. The mature mammals and the human child are also phylogenetically and ontogenetically less advanced in the shifting of the white blood-picture to the left. In many respects the nursling corresponds to the ordinary mammal.—*Henry F. Nachtrieb.*

8252. **GOSS, CHARLES M. Microdissection of human polymorphonuclear neutrophiles.** *Arch. Exp. Zellforsch. Bes. Gewebezücht. (Explantation)* 10(2): 213-220. 3 pl. 1930.—Human leucocytes were prepared for micromanipulation by removing the clot from a drop of blood. The neutrophil showed no marked divergence from Chamber's description of the physical structure of cells in general: but the cell membrane, in this case, seemed more nearly a naked surface than he ascribed to most cells. This might be due to the fact that there could be no intercellular cement substance, and a protective covering was unnecessary in the circulating blood stream. The cytoplasm was more liquid than that of the monocyte and clasmatocyte, and the decrease in viscosity which followed mechanical agitation was particularly well shown.—*From author's summary.*

8253. **HEATH, CLARK W., and GENEVA A. DALAND. The life of reticulocytes: experiments on their maturation.** *Arch. Internal Med.* 46(3): 533-551. 5 fig. 1930.—Reticulocytes in vitro at 37° C. and in the pleural cavity of the rabbit decrease at a regular rate over a period of 1-4 days. This rate is analogous to a death rate or a maturation rate. The rate is similar for reticulocytes from bled rabbits, from those into which phenylhydrazine is injected, from cases of hemolytic jaundice and from cases of pernicious anemia. The rate is much slower at 23° C. or at 10° C. than at 37° C. Reticulocytes have been found in blood kept in the icebox for 6 mos. The decrease in the number of reticulocytes is not related to degenerative changes which may take place in the blood in vitro. As the reticulocytes decrease in number in vitro, cells with "granules" progressively increase. Reticulocytes having large amounts of reticular substance are less mature than those having small amounts of reticular substance and require a longer time to reach maturity. There is an undoubted analogy between the rate of decrease in the number of reticulocytes in vitro and of those in the blood stream. In both instances this is probably true maturation. Evidence in favor of this conclusion is given by studies on reticulocytes from the blood of patients with pernicious anemia during the reticulocyte responses following liver therapy.—*Authors' conclusions.*

8254. **HENRIQUES, V., und H. OKKELS. Das weitere Verhalten experimentell erzeugter Eisenablagerungen innerhalb der parenchymatösen Organe.** *Zeitschr. Wiss. Biol. Abt. B. Zeitschr. Zellforsch. u. Mikrosk. Anat.* 12(1): 155-166. 7 fig. 1930.—The authors had previously found that colloidal Fe compounds were almost electively stored in the reticulo-endothelial system (R.E.S.), complex Fe salts [Na ferricitrate] predominantly in the hepatic cells. Rabbits on an oat, hay, and root diet were injected for 7-9 days with colloid Fe albuminatum or Na ferricitrate; 2-3 biopsy specimens of the liver were removed in the course of wks. or mos., the animals killed and sections of liver, spleen, and kidney examined. The animals treated with colloidal Fe often showed signs of late intoxication, the others did not. The Fe was taken up most quickly by the Kupffer cells in the R.E.S. but was given up in a few wks.; storage in the histiocytes occurred a little later, in time the dye was condensed in the perilobular histiocytes and only slowly freed. When the characteristic perinuclear Fe granules were first formed they persisted for several mos., the hepatic cells gradually losing the Fe after 6 mos. from within outward. Deposition here seemed much more stabile than in the R.E.S. The hepatic cells did not empty so completely as the Fe-containing Kupffer cells. After some months, however, storage in giant histiocytes was found perilobularly, particularly in the spleen. A great deal indicates that Fe is eliminated from the cytoplasm by chemical transformation. The final state of the Fe deposits occurred in the giant histiocytes of the spleen, from which the Fe could no longer be mobilized.

Über die Bildung von Erythrocyten aus den Hämatoblasten im Blute von Amphiuma means und Batrachoseps [sic] attenuatus Esch.** [The formation of erythrocytes from the hematoblasts in the blood of A. means and B. attenuatus.] *Zeitschr. Wiss. Biol. Abt. B, Zeitschr. Zellforsch. u. Mikrosk. Anat.* 11 (3/4): 727-737. 29 fig. 1930.—Chiefly discussion of a series of illustrations.

8257. **LOEWENTHAL, N. Des variétés de globules blancs du sang chez Bombinator pachypus et Salamandra atra.** *Arch. Anat. Hist. et Emb.* 9(8): 469-508. 1 col. pl. 1928/1929.—Detailed histological description of the different types of leucocytes found in blood smears from *B. pachypus* are presented. The leucocytes are divided into 2 main groups: (1) with no granules or few non-specific azurophile granules, and (2) with specific granules. Under (1) are classed typical small lymphocytes and larger cells related to neutrophiles. These lymphocytic forms are completely separated from the small and large mononuclears, which are thought to be closely related to each other. Under (2) are described 3 varieties with specific granules, (a) neutrophiles, present in a great variety of forms; (b) eosinophiles; and (c) basophiles, of which 2 distinct types are described, the first with vivid blue-violet granules and the second with bluish-red granules. In all three groups a variety of forms was present which suggested the possibility of differentiation occurring in the blood stream. Differential counts compared with those from *S. atra* show in both a higher percentage of lymphocytes (50-70%), higher in *Bombinator* (60-70%), whereas the neutrophile count was higher in *Salamandra* (27-28%). The

basophile count was relatively high in both species, and in *Bombinator* a larger number of developmental forms was found. In mononuclears all variations leading from smaller to larger cells were seen. Azurophilic and pigment granules were found. The presence of vacuoles in larger cells indicated their regressive character.—*J. S. Latta.*

8258. **MAGLIULO, ALFONSO.** Influenza dello stato del sistema reticolo-endoteliale sull'attecchimento dell'innesto ovarico omoplastico sperimentale. [Influence of the state of the reticulo-endothelial system on the attachment of homoplastic ovarian transplants.] *Lo Sperimentale* 84 (5/6) : 393-429. 13 fig. 1930.—In the livers of young ♂ and ♀ rabbits, previously castrated, were engrafted ovaries from rabbits 20-35 days old. Such animals were repeatedly injected intravenously either before or after the grafting with a 10% soultion of saccharated iron oxide. The ovarian grafts grew and maintained their morphology for a limited period only.—*M. L. Menten.*

8259. **MAGRASSI, FLAVIANO.** Il tessuto reticolato del fegato degli Urodeli. (Contributo all'istologia e all'istogenesi delle fibre a graticcio e del reticolo linfoadenoide.) [The reticulated tissue of the liver of urodeles (histology and histogenesis of lattice fibers of the lymphadenoid reticulum).] *Arch. Ital. Anat. e Embriol.* 28 (1) : 86-102. 5 fig. 1930.—Histologic study of the liver in larvae of *Triton cristatus* showed that the reticular fibers exist within the capillaries and the hepatic capsule before the formation of the lymphoid reticulum and the lattice fibers. The lymphoid reticulum develops from fibrillae originally rectilinear, which end in the distinctly reticulated membrane of the hepatic capsule; the lymphoid reticulum develops much more rapidly than do the lattice fibers. The lattice fibers of the *Triton* liver are probably derived from the primitive fibrillar perivasal reticulum of the blood vessels or from their reticular adventitia. In the adult *T. cristatus* the reticulated tissue of the liver was represented by argentophil fibers and by cells many of which could be identified with the adventitial cells of the blood vessels; others probably belong to the reticulo-histiocytic system. In the cortical lymphoid stratum and in the deep lymphoid islands the reticulated tissue is represented by fibers but no cells can be distinguished which can be regarded as cells of the reticulum. The lattice fibers of the hepatic parenchyma are continuous with the reticular fibers of the cortical lymphoid stratum and of the deep lymphoid islands. The author holds that the reticular fibrillae and the lattice fibers are identical.—*From author's summary (transl.).*

8260. **MOSCZYTZ, NORB.** Hämatologische und kritische Studien zum Monozytenproblem. *Zeitschr. Klin. Med.* 106 (5/6) : 582-616. 4 fig. 1927.—The author believes that monocytes under some conditions are produced by the bone marrow, under others by the reticulo-endothelial system, and under still others by the lymphocytes.

8261. **NOEL, R., et H. PIGEAUD.** Le chondriome des éléments hématopoiétiques dans le foie du foetus humain. *Bull. Hist. Appl. Phys. et Path.* 7 (5) : 162-166. 3 fig. 1930.—Mitochondria of blood producing cells are characterized by a definite size, form, and grouping for each type of cell and these patterns are identical with those of azurophil granules by other techniques.—*J. G. Sinclair.*

8262. **PAOLUCCI, FRANCESCO.** Sul sistema reticolo-istiocitario o di Goldmann nel callo osseo (e sulla funzione fagocitaria dei megacariociti). (Ricerche sperimentali.) [The reticulo-histocytic system in bone callus and the phagocytic function of the megakaryocytes.] *Ann. Ital. Chir.* 9 (10) : 1012-1029. 7 fig. 1930.—Trypan blue was subcutaneously injected into rabbits, the left radius was fractured in each, and the callus formation was studied in preparations made at various intervals from the 2nd to the 60th day. The elements of the reticulo-histocytic (reticulo-endothelial) system were in evidence from the 48th hr. on, were more numerous in the 1st period of callus formation, and gradually disappeared in the 2nd period. The osteoblasts, the cartilaginous and osseous cells, and the megakaryocytes never contained granules of the dye and the author therefore excludes them from the reticulo-histocytic system.

8263. **PINUS, A.** Die Reaktion von Gewebekulturen auf Inokulation mit B. mallei. *Arch. Exp. Zellforsch. Bes. Gewebezücht. (Explantation)* 10 (1) : 109-112. 2 fig. 1930.—Tissue cultures of spleen of the white mouse grown in horse serum were placed for 15-20 min. in emulsions of *B[acillus] mallei* (conc. 60-100 bacilli in a visual field). Best growth was obtained on spleen from mice 1-2 days to 3 weeks old; 2 cultures on spleen from newborn white rats and from a guinea pig embryo did not give satisfactory growth; 1 culture from a pigeon embryo was luxuriant. Radial fibroblast growth appeared after 24-30 hrs. On the 4-6th day there was increased proliferation of cells of the macrophage type. Both macrophages and fibroblasts phagocytosed bacilli. Mitoses were abundant in both control and inoculated cultures.

8264. **PÓVOA, HELION.** Microglia e systema reticulo-endothelial. [Microglia and reticulo-endothelial system.] *Arch. Brasileiros Med.* 20 (7) : 296-299. 1930.—The author describes histologic results from blockage of the reticulo-endothelial system in 8 rabbits, from which he concludes that the microglia is the most important portion of the reticulo-endothelial system in the nervous tissues.

8265. **WINDFELD, PETER.** Über Blutplättchen-Zählung. *Acta Med. Scandinavica* 73 (1) : 10-18. 1930.—The author briefly reviews methods and difficulties of counting platelets and describes the application of Petri's method for rabbits for clinical laboratory use. In this procedure all glassware used in collecting blood was previously bathed in 6% olive oil-ether. About 2 cc. venous blood was collected and mixed with Na citrate in proportion of 1 : 10, then centrifuged 2-3 minutes at a rate of 1500. Clear plasma was pipetted off into a small reagent glass and, after standing for ½ hour, counts made in a closed Thoma-Zeiss counting chamber 1/20 mm. deep. A series of 10 counts showed an average variation of 33% from the mean.—*J. S. Latta.*

NEUROLOGY

8266. **BECCARI, NELLO.** I centri tegmentali nell'asse cerebrale dei Selacei. [The tegmental centers of the cerebrospinal axis of Selachii.] *Arch. Zool. Ital.* 14 (2/4) : 411-430. 1 pl., 5 fig. 1930.—This mémoire contains a complete illustration of the nuclei composing the tegmental center of the cerebral axis of the Selachii. Using the Cajal method on embryos of *Scyllium canicula* and *Pristiurus melanostomus,* the author finds a mesodiencephalic tegmental center (in which a pretrigeminal nucleus and a principal group are distinguishable), a metencephalic and a myelencephalic tegmental center. The pretrigeminal nucleus, the metencephalic principal group and the myelencephalic center correspond to the 3 reticular nuclei described by van Hoewell in *Raia.* —*Author's summary.*

8267. **BUSCH, E.** Studies on the nerves of the blood vessels, with especial reference to periarterial sympathicectomy. *Acta Pathologica et Microbiologica Scandinavica. Suppl.* 2. p. 1-186. 11 pl. 1929.—The author reviews the literature on the anatomy and physiology of the nerve supply to blood vessels. He describes the technic used and the results in his anatomical and physiological study on frog, guinea pig, rabbit, and man. A section is devoted to the literature on periarterial sympathicectomy and a résumé of the entire study in English, German, French and Danish.—*E. A. Baumgartner.*

8268. **CHRIST, HEINRICH.** Der Nervus vagus und die Nervengeflechte der Vormägen der Wiederkäuer, speziell der Haube. *Zeitschr. Wiss. Biol. Abt. B, Zeitschr. Zellforsch. u. Mikrosk. Anat.* 11 (2) : 342-374. 25 fig. 1930.—While it is well known that in cattle there is no clearly differentiated ganglion nodosum in its typical place on the vagus nerve, the author found, in all cases examined (16

cattle embryos, 6-8½ mos., 6 goats, 1 sheep, and 1 sheep embryo), a ganglionic thickening at the level of the 7th cervical vertebra, located just before the separation of the sympathetic from the vagus. In its entire structure it was strikingly similar to the ganglion nodosum of other animals. The author names this the cervical ganglion of the vagus. From it arises a part of the fibers which later separate from the vagus and constitute the "combined ventral" root. Exact investigations of the points of union of the vagus showed that no ganglion cells occur there. The dorsal branch of the vagus sends a large number of fibers to the dorsal part of the reticulum (Haube). In the intermuscular connective tissue of the reticulum is found a thick ganglionic network which is thickest in the region of its fundus and shows many similarities to the plexus myentericus of Auerbach. The intermuscular connective tissue of the psalterium contains a close ganglionic network which is denser than that of the reticulum, in contrast to the results given by Ellenberger and Marschall. In the paunch there is a wide meshwork of nervous tissue with ganglionic fields.—*Author's summary* (*transl. by J. M. Nielsen*).

8269. COGHILL, G. E. Correlated anatomical and physiological studies of the growth of the nervous system of amphibia. IX. The mechanism of association of Amblystoma punctatum. *Jour. Comp. Neurol.* 51 (2): 311-375. 14 pl. 1930.—A description of the differentiated neural system in the cerebrum and sensory or association part of the rhombencephalon and spinal cord in the 4 physiological stages of development: nonmotile, early flexure, coil, and early swimming stages. Throughout the system neuroblasts differentiate out of the neuro-epithelium before fibers grow into their vicinity from more or less distant neurones, and their primary polarity has reference to centers of differentiation; growth toward the receptor field is secondary, in sensory as well as motor elements. No evidence is found that ingrowing nerve fibers activate the differentiation of neuroblasts out of indifferent cells. The efferent system of the cerebrum is primary; the afferent, secondary. The general pattern of the association paths in the cerebrum is established before there is any evidence of conduction of nervous impulses into it, either from the receptor field or from below through the isthmus. Commissural association systems develop in the cerebrum before they do below the isthmus, there being none in the rhombencephalon and spinal cord when locomotion is established. In these parts the commissural fibers of the period arise within the motor system.—*Author* (*courtesy Wistar Bibl. Serv.*).

8270. COMINI, ADELE. Ricerche istologiche sui plessi coroidei dei mammiferi. [Histologic study of the choroid plexus in mammals.] *Riv. Sperim. Freniatria* 53 (3/4): 460-485. 6 fig. 1930.—The material studied comprised representatives (number not stated) of the following species: *Erinaceus europaeus* L., *Rhynolophus ferrum-equinum* Schreb., *R. euryale* Blas., *Lepus cuniculus* L., *Arctomys marmota* L., *Mus decumanus* Pall., *Cavia cobaya* Marcgr., *Felis domestica* Briss., *Canis familiaris* L., *C. vulpes* L., *Sus scropha* L., *Bos taurus* L., *Ovis aries* L., *Equus caballus* L., *Cercocebus lunulatus* Temm., *Homo sapiens* L. The epithelial cells constantly showed vibratile cilia; the nuclei were large, round, sac-like, and poor in chromatin, with no signs of division; the protoplasm was abundant, non-homogeneous, and presented inclusions of various types; the chondriome was generally abundant, usually in the form of short, slender chondriocontes; fats and lipoids, in some species particularly, were abundant in various forms; glycogen was present in some species, and sometimes a pigment, apparently hemosiderin; melanin was absent. The connective tissue in the choroid plexuses was usually considerable, and presented a variable amount of fundamental substance and of cellular elements of various types—granular cells of the type described by Sundwall, reticulo-endothelial elements of various forms, cells containing fats and lipoids, glycogen-bearing cells, etc.; melanin was rare.—*From author's summary* (*transl.*).

8271. DAVENPORT, H. A., S. W. RANSON, and E. H. TERWILLIGER. Nuclear changes simulating inclusion bodies in dorsal-root ganglion cells. *Anat. Rec.* 48 (2): 251-255. 1 pl. 1931.—Dorsal-root ganglia of dogs, cats, and turtles were immersed in hypertonic salt solutions and subsequently fixed in Zenker's fluid. The nuclear substance underwent condensation and formed an artefact which resembled the nuclear inclusions of virus disease. The clumping of the chromatin was not dependent upon a critical pH of the hypertonic solution, but not all hypertonic salt solutions caused it. The exceptions were KCl and urea.—*Authors* (*courtesy Wistar Bibl. Serv.*).

8272. HINES, MARION. Studies on the innervation of skeletal muscle. III. Innervation of the extrinsic eye muscles of the rabbit. *Amer. Jour. Anat.* 47 (1): 1-53. 6 pl., 4 fig. 1931.—Studied with methylene-blue-injection method, 4 morphologically distinct types of nerve endings, other than those on blood vessels, in the extra-ocular muscles of the rabbit are: terminaisons en grappe, naked endings, "accessory" terminations, and motor end plates. The grape-like terminations originate from heavily medullated nerve fibers, from non-medullated or thinly medullated nerve fibers, and from non-medullated axis cylinders sharing in common with the motor end plate a medullated nerve fiber. The naked endings are branches of medullated nerve fibers or continuations of non-medullated axis cylinders, which, coursing parallel to the muscle fiber, end nakedly upon it. The "accessory" terminals are accessory because they are nerve terminations upon a muscle fiber, innervated also by a motor end plate. These endings may be epilemmal or hypolemmal, and are characteristic of the middle-third. Unaccompanied motor end plates occur commonly in the origin-third. When the oculomotor nerve is cut at the base of the brain, these nerve endings and their supplying nerve trunks degenerate. If the cervical sympathetic trunk is ablated, the nerve terminals upon muscle fibers are undisturbed, but the innervation upon the smaller blood vessels is lost. A combination of these 2 experimental procedures completely denervates these muscles. Therefore, the innervation of the muscle fibers within the rabbit's extra-ocular muscles originates from the oculomotor nerve and that of the blood vessels, from both the third nerve and the cervical sympathetic.—*Author* (*courtesy Wistar Bibl. Serv.*).

8273. IDE, HIRO. On several characters shown by the cross-sections of the median and sciatic nerves of human males according to race. *Jour. Comp. Neurol.* 51 (2): 457-487. 1930.—Cross-sections from like levels of the median and sciatic nerves of 21 white males and 29 negro males were prepared and examined for the areas of the entire section, the number of fasciculi, the area of the fasciculi, and the area of the largest fibers. Each of these 4 measurements gave a higher value for the negro when compared on the basis of the entire series or with the data in 4 groups for each race. In 7 out of the 8 comparisons the differences are statistically valid. Between white males and negro males there is, therefore, a race difference in the characters of the median and sciatic nerves as here measured. The relations found for the 2 nerves studied are probably true for the spinal nerves as a class.—*Author* (*courtesy Wistar Bibl. Serv.*).

8274. IDE, HIRO. On several characters shown by the cross-sections of the median and sciatic nerves of human females and a comparison of these with the corresponding observations on the male nerves from whites and negroes. *Jour. Comp. Neurol.* 51 (2): 489-521. 1930.—The sectional areas of the median and sciatic nerves of man have been considered according to sex in the white and negro races. The characters studied were: the entire area, the number of fasciculi, the area of the fasciculi, and the area of the largest fibers. According to race: All measurements give higher values for the negro ♂ compared with the white ♂ and for the negro ♀ compared with the white ♀. According to sex: The

measurements for the ♀ are above those for the ♂ in both races, except in the case of the entire area where the ♀ gives values below those for the ♂. This is due to the smaller amount of connective tissue in the ♀ nerves. As compared with the median nerve, the sciatic is larger in the ♀ than in the ♂. The most significant differences here observed are in the areas of the fibers, and it is inferred that the conduction rate will be more rapid in those individuals with the larger fibers.—*Author* (*courtesy Wistar Bibl. Serv.*).

8275. IDE, H. On the sectional areas of the lumbar nerve roots and of the largest fibers in them, in the albino rat, according to sex. *Jour. Comp. Neurol.* 51(2): 441-456. 1 fig. 1930.—Having found that the sectional areas of the median and sciatic nerves and of the fibers in them are larger in the ♀ albino rat than in the ♂ of the same size, the author sought to determine whether the same relations held in the spinal roots of these nerves. In the present observations, limited to the roots of the 4th and 5th lumbar nerves, the dorsal root exceeds the ventral in sectional area. The area relations, according to sex, are the same for both roots and are similar to those previously found in the sciatic nerve. The sectional areas of the largest fibers are greater in the ventral than in the dorsal roots, but are related, according to sex, as are the areas of the roots. When the areas of the nerves, or their roots or the fibers in them, are determined for ♂♂ and ♀♀ of like age, it is found that the sectional areas are alike in the 2 sexes. Thus, the growth in sectional area is a function of age and independent of body size, according to sex.—*Author* (*courtesy Wistar Bibl. Serv.*).

8276. LASSEK, ARTHUR M., LESLIE W. DOWD, and ARTHUR WEIL. The quantitative distribution of the pyramidal tract in the dog. *Jour. Comp. Neurol.* 51(1): 153-163. 1930.—In studying degenerated pyramidal tracts of the dog stained by the Marchi, Pal-Weigert, and Weil methods, it was calculated that 55% of the tract in the spinal cord passes to cervical segments, 20% goes to thoracic segments, and 25% is distributed to lumbar and sacral segments. Cervical segments supply 40% of the musculature; thoracic segments, 25%, and lumbar and sacral segments, 35%. The number of pyramidal-tract fibers supplying different groups of spinal-cord segments was estimated, and from this number was computed the amount for 1 gm. of muscle: C_{1-4}, 104 fibers; C_5-T_2, 24; T_{3-12}, 21, and L_1-S_3, 22 fibers to every gm. Weil and Lassek ('29) found that the relative distribution of pyramidal-tract fibers within the spinal cord of man is the same as in the dog. The number of nerve fibers corresponding to 1 gm. of muscle is the same in the cervical and lumbar segments of man and dog. The discrepancy in the supply of musculature innervated by T_{3-11} in man and T_{3-13} in the dog (62 and 22 fibers, respectively) is explained by the fact that the weight of muscles in the thoracic region of man is only 6.8% of the total musculature innervated by the spinal cord, as compared with 24.2% in the dog.—*Authors* (*courtesy Wistar Bibl. Serv.*).

8277. LEWIS, DEAN, and WALTER E. DANDY. The course of the nerve fibers transmitting sensation of taste. *Arch. Surg.* 21(2): 249-288. 7 fig. 1930.—Pure isolated divisions of the 5th, 7th, and 9th nerves were performed subtentorially for the relief of surgical conditions; also combined division of the 5th and 7th. The 5th nerve was divided intracranially at the pons for trigeminal neuralgia. The subtentorial operation has the advantage of not disturbing the petrosal nerves or geniculate ganglion or any other cranial nerve. Division of the 7th nerve alone has occurred during the removal of tumors of the cerebellopontine angle. As yet it has been impossible to extirpate these tumors without dividing the 7th nerve. As the 5th and 9th nerves are usually pushed aside by these tumors, they may not be injured when the tumor is removed. There is also an instance of a pure lesion of the 7th nerve which was accidentally injured when the auditory nerve was divided for relief from Ménière's disease. There was no disturbance of the 5th or 9th nerve in this case. Intracranial division at the brain stem of the 9th nerve or of the sensory root of the 5th nerve or of both nerves was not accompanied by permanent loss of taste to the anterior $\frac{2}{3}$ of the tongue. Total loss of taste on the anterior $\frac{2}{3}$ of the tongue invariably followed intracranial division of the 7th nerve (at the pons) or of the peripheral portion at any point between its exit from the pons and the geniculate ganglion, from which point the fibers pursued a separate course. At times there might be a temporary loss or diminution in acuity of taste following operations on the gasserian ganglion or the sensory root of the 5th nerve, but later taste returned to normal. Initial loss of taste, with subsequent return, was noted by Köster and Cushing after operations on the gasserian ganglion. They assumed that another nerve had taken over the function of conducting sensations of taste in these cases. This assumption seems improbable to the authors in the present cases: they have no experimental or clinical observations which would warrant such an assumption.

8278. NODA, M., und G. YASUZUMI. Über die Frommann'schen Linien der Achsenzylinder der Nervenfasern. *Folia Anat. Japonica* 8(6): 439-456. 4 fig. 1930.—Since its discovery by Frommann in 1864, many investigators have studied this line. There are 2 theories regarding its nature: one theory assumes that the image must be an artifact; the other, that the line is a natural structure of the axis cylinder. In 1910, Retzius, finding a clearly coiled image, declared that the line is a natural product. The writers have discovered that "Frommann's line" is mathematically the same as the rhythmic deposit or the Liesegang's phenomenon, and they have also succeeded in forming the coiled image in a test-tube. They conclude, therefore, that the image is not a natural structure existing only in the axis cylinder, but an artificial product. Secondly, they believe that the "ports of infiltration" of $AgNO_3$ are cracks of the medullary sheath or Ranvier's node.—*Authors* (*courtesy Wistar Bibl. Serv.*).

8279. OKAMURA, CHOHNOSUKE. Über die Ganglienzellen in der Herzwand. *Zeitschr. Ges. Anat. Abt. 1, Zeitschr. Anat. u. Entwicklungsgesch.* 89(3): 344-366. 10 fig. 1929.—Investigation of the nervous system of the heart with the Ag impregnation method, and methylene blue, hematoxylin eosin, and van Gieson's stains revealed 3 types of ganglion cells. The first type of neurons, belonging to the vagus, was 17-25 μ in diam., and was always oval or elliptical. All the processes of the cells communicated with the sympathetic nerve trunks or ganglion cells. These cells were found only in the trunks of the vagus and in the ganglia of Remak, Ludwig and Bidder. The 2nd kind was irregular, 5-20 μ in diam. The neurites communicated with the sympathetic nerve trunks or ganglion cells. These cells were in the epi- and endocardium (very rarely in the myocardium) from the sinus and auricle to the apex of the ventricle, and were therefore called sympathetic sensory ganglion cells. The 3rd type was chiefly fusiform, belonging to the sympathetic motor cells, and could be subdivided into large and small neurons, single or forming ganglia, and were not only in the subepicardium but in the myo- and subendocardium. Especially between all muscle fibers were many small ganglion cells which, with their processes, formed the plexus perimuscularis. These relations of the motor cells were the same from the sinus to the apex of the heart, but the dimensions of the cells gradually became less toward the periphery and in the apex only slender cells were found. At the boundary of the auricle and the ventricle were many nerve elements (related to both structures), which contained many strongly medullated and non-medullated nerve trunks, with ganglia and motor or sensory ganglion cells lying alongside them. In the Keith-Flack or Aschoff-Tawara bundles, the author found the same nervous structures as on the other muscle fibers of the heart, but the ganglia and ganglion cells were far more numerous.—*C. Okamura.*

8280. OKAMURA, CHOHNOSUKE. Über den Nervenapparat der Gefässwand. *Zeitschr. Ges. Anat. Abt. 1, Zeitschr. Anat. u. Entwicklungsgesch.* 91(4): 528-537. 5 fig. 1929.—The author investigated with methylene blue and Golgi's Ag impregnation methods all blood vessels from the aorta and vena cava to the capillaries of the frog, toad, sparrow, hen, mouse, rat, guinea-pig, rabbit, cat, dog, swine, horse, cow and man. In the perivascular nerve-plexuses of all blood vessels many sympathetic motor-ganglia and ganglion cells, and sensory ganglion cells were found. These nerve-plexuses go into the media and there form plexuses again which have the same cell types but only a very few sensory cells. The processes of the cells twist round the muscle-fibers and from the "plexus perimusculares" with varicosities at their ramifications. These varicosities represent the endings of the motor-nerves in the course of this fine plexus on the sarcolemma. The sensory nerve-plexuses built up from ganglion-cells and their processes are disposed in the intima just as in the endocardium of the heart (see preceding entry). The nervous apparatus of the smallest blood vessels is very simple and has no sensory plexus in the intima. But the sensory ganglion-cells in the adventitia and the motor ganglion cells are always between all muscle-fibers. There are 2 nerve plexuses around a capillary. The inner plexus is formed by motor-ganglion-cells, and their processes twist round the endothelial cells of the capillary. The external plexus is composed of sensory ganglion-cells and their processes, and has here and there communications with the motor-plexus.—*C. Okamura.*

8281. PAPEZ, JAMES W. The brain of Sutherland Simpson, 1863-1926. *Jour. Comp. Neurol.* 51(1): 165-196. 18 fig. 1930.—Photographs and drawings of the surface anatomy of the brain together with a descriptive study of the gyri and sulci in its several regions are presented. The various lobes of the brain have been measured and indexed in such a way as to show their relative size and to make possible comparisons with other published papers. These measurements have been made in connection and comparison with those of 20 other men and 20 women. The length and depths of the principal sulci have been measured and tables of their total values have been compiled for the frontal, parietal, occipital, and temporal regions. The main features of this brain were its generally large size and a wealth of convolutional development in the parietal, occipital, and temporal regions. The outstanding feature was the exceptionally large size of the precuneus. The frontal region was of average size, but the inferior frontal convolution in its anterior part was strongly developed.—*Author (courtesy Wistar Bibl. Serv.).*

8282. PAPEZ, JAMES W., and G. LaVERNE FREEMAN. Superior colliculi and their fiber connections in the rat. *Jour. Comp. Neurol.* 51(2): 409-439. 3 pl., 1 fig. 1930.—Lesions were placed in the superior colliculi of 20 rats, and then the animals were tested in the light-discrimination maze. There is a rough correlation between the extent of injury to the tectum and to the following fiber tracts and the retardation in the maze. A Marchi study of the brains of these rats showed that the tectal region has 3 main efferent fiber connections, as follows: (1) The tectospinal tracts arise in the cortex of the colliculi and pass down to the lower centers of the spinal cord. (2) The tectopontal tracts arise in the posterior part of the tectum and pass ventrally into the tegmental region and into the lateral nucleus of the pons. They appear to form the first link in tegmental and cerebellar connections. (3) The fibers of the posterior commissure arise in the posterior nucleus of the thalamus and pass across to end in the interstitial nucleus and neighboring central gray matter. From the interstitial nucleus fibers pass down in the medial longitudinal fasciculus. The posterior nucleus of the thalamus and the nucleus of the posterior commissure send fibers into the internal capsule and thence to the medial occipital cortex. —*Authors (courtesy Wistar Bibl. Serv.).*

8283. PODESTA, E., e G. FORNARI. Ricerche sulle terminazioni nervose motrici nella siringe del gallo domestico. [Studies of the nervous motor endings in the syrinx of the cock.] *Boll. Soc. Ital. Biol. Sperim.* 5(3): 375-377. 1930.—The material was prepared by Ruffini's Au impregnation method. In the muscles of the syrinx of cocks 2 kinds of endings were present: "terminaisons en grappes" and sole plate endings. The first were more abundant, and were found in fibers with a rich sarcoplasma content, the others in fibers with abundant myofibrillae. In no muscle fiber were the 2 kinds of endings simultaneously present. Also epilemmal "terminaisons en grappes" were found. It is suggested that the "terminaisons en grappes" are concerned with muscle tonus and the sole plate endings with muscular contraction, whereas the epilemmal terminations are sensory endings.—*M. Comel.*

8284. RASMUSSEN, A. T. An aberrant (recurrent) pyramidal bundle in the cat. *Jour. Comp. Neurol.* 51(1): 229-235. 8 fig. 1930.—This crossed bundle of fibers separates from the pyramidal decussation in the lower part of the medulla oblongata and courses dorsally and then upward in the medial and then in the dorsal part of the dorsal nucleus of the vagus on the opposite side with reference to the pyramid from which it arises. As it ascends it breaks up into several strands which move laterally but remain close to the substantia gelatinosa centralis. As these fasciculi pass along the dorsal part of the medial vestibular nucleus, there is further separation into 7 or 8 smaller bundles which ultimately disappear in the region of the mesencephalic root of the trigeminus on a level with the upper pole of the chief sensory nucleus of the fifth cranial nerve. Another case (also in a cat) is on record which is surprisingly like this one in every respect, except that the bundle remained uncrossed. This could be ascertained with great certainty, because it was a Marchi series in which the internal capsule had been cut on one side and the abnormal bundle arose from the degenerated pyramid at the decussation. Similar and somewhat more deeply and laterally situated fibers are described also in man, but at least some of these are not recurrent in direction.—*Author (courtesy Wistar Bibl. Serv.).*

8285. RIOCH, DAVID McK. A note on the center median nucleus of Luys. *Jour. Anat.* 65(3): 324-327. 2 pl. 1931.—The material studied consisted of serial, transverse sections of the brains of *Cercopithecus, Cebus capucinus, Lemur catta, Canis familiaris* and *Felis domestica* stained by the Weigert-Pal method, and of *Phoca vitullina* stained by the Giemsa method. The center median lies in the caudal portion of the internal medullary lamina, at the level of the habenulo-peduncular tract. Caudo-medially, especially in lower mammals, it fuses with the nucleus parafascicularis. It is probably present in all mammals, but is larger and better differentiated in the higher forms.

8286. RODRIGUES, ALVARO. Communicating branches between the cervical sympathetic and the descendens cervicalis. *Jour. Anat.* 64(3): 308-318. 11 fig. 1930.—From dissections of 45 bodies, 26 adults (19 ♂♂, 7 ♀♀), 1 ♀ child 4 yrs. old, and 18 fetuses (12 ♂, and 6 ♀), the author declares communicating branches to be not rare but very common. He classifies them under 6 fundamental types: (1) branches from the superior cervical ganglion; (2) branches from the ramus communicans to C II; (3) branches from the ramus communicans to C III; (4) branches from a ramus communicans joining the loop between C II and C III; (5) filaments joining the loops between the cervical spinal nerves or joining these nerves close to the points whence arise the roots of the N. descendens cervicalis; (6) such close association between the ramus communicans to C II and one or more roots of the N. descendens cervicalis arising from C II that it may be regarded as assisting their formation.

8287. SCHLAEPFER, KARL. Weiterer Beitrag zur Frage der motorischen Innervation des Zwerchfelles. [Innervation of the diaphragm.] *Arch. Klin. Chir.* 164: 233-239. 7 fig. 1931.—Substantiating previous 136-day experiments on dogs, phrenicotomy in the intrathoracic

area in a dog led in 2 yrs. to complete atrophy of the entire half of the diaphragm. Had any portion been supplied by another nerve, intact or even hypertrophic muscle would have been present. The phrenic is the only motor nerve supplying the diaphragm of the dog.

8288. **SHANER, RALPH F. On the development of the nerves to the mammalian heart.** *Anat. Rec.* 46(1): 23-38. 3 pl. 1930.—The development of the cardiac nerves and plexuses to the calf heart, together with details of the innervation of the nodes, is followed from the earliest embryos to the adult. Three vagus branches on either side grow to the calf heart: (*a*) a nerve to the common cardinal vein, (*b*) a nerve to the pulmonary artery, and (*c*) a nerve to the ductus arteriosus and aorta. The earliest plexuses appear at the ends of the nerves. A twig from the nerve to the right common cardinal vein ramifies over the site of the sino-atrial node long before the node appears. A twig from the plexus covering the sinus venosus runs beneath the atrial septum to the atrioventricular node. The sympathetic nerve supply apparently follows the same general plan.—*Author (courtesy Wistar Bibl. Serv.).*

8289. **STARKIE, C., and D. STEWART. The intramandibular course of the inferior dental nerve.** *Jour. Anat.* 65(3): 319-323. 3 fig. 1931.—Until 2 yrs. ago, it was generally accepted by dental surgeons that the inferior dental nerve of 1 side overlapped as far, at least, as the canine tooth of the opposite side. Study of dissecting room subjects, supplemented by the mandibles of some of the commoner mammals, established that there are 2 definite plexuses: (a) a postero-internal alveolar plexus; (b) an antero-external incisor plexus. The molars and bicuspids receive their nerve supply from the alveolar plexus, the incisors from the incisor plexus, and the canines from either of them. The inferior dental nerves do not always extend across the symphysis and so overlap. If such an overlap is present it seldom extends beyond the central, and never beyond the lateral, incisors of the opposite side.

8290. **WOOLLARD, H. H. The innervation of the ocular muscles.** *Jour. Anat.* 65(2): 215-223. 2 fig. 1930.—From study of ocular muscles of cat, dog, rabbit and man, the author concludes that there are 2 types of nerve fibers concerned in the innervation of the eye muscles: the ordinary medullated type with motor terminal plates and a 2nd finely medullated or non-medullated, forming several claw-like endings, usually epilemmal, but occasionally hypolemmal. The medullated fibers are related to thicker muscle fibers, while the non-medullated are related to thinner muscle fibers. It has not been observed that the thinner muscle fibers also receive a medullated ending. This mode of innervation, if not peculiar to eye muscles, is at any rate restricted to a narrow group of muscles, and does not obtain in the trunk or appendicular muscles. The fibers composing this finer system leave the brain stem in the trunks of the ocular nerves as medullated fibers. They probably lose their myelin sheaths when nearing their final distribution. Evidence has been obtained that these fibers have their origin in the cranial extension of the tractus mesencephalicus of the 5th nerve where this is on a level with the 3rd nerve nucleus. The strong presumption that this special system, in its greater part at any rate, is the sensory supply of the eye muscles is made almost certain if this source from the mesencephalic root of the 5th is confirmed.—*Author's summary.*

GENITO-URINARY SYSTEM

8291. **CHIGI, CALLISTO. Contributo allo studio della parete dei tubuli seminiferi retti e delle lacune della rete testis. [Morphological studies on the wall of the tubuli seminiferi recti and of the lacunae of the rete testis.]** *Bol. Soc. Ital. Biol. Sperim.* 5(3): 346-347. 1930.—The author demonstrated the presence of a basal membrane in the wall of the tubuli recti as well as in that of the lacunae of the rete testis.—*M. Comel.*

8292. **FORAMITTI, C. Über das Schicksal von transplantiertem Hodenparenchym.** *Wien. Arch. Inn. Med.* 21(2): 315-318. 2 fig. 1931.—Biopsy specimens from an autotesticular (2½ yr.) and from a homotesticular (8½ mo.) pedicled graft (with later division of the pedicle) in man showed that the interstitial cells were preserved (with normal cell nuclei), the seminal tubules were greatly narrowed; Sertoli's cells were normal in the autotransplant, only partially retained in the homotransplant.

8293. **GLAS, RUDOLF. Über das Vorkommen von Fettzellen in der menschlichen Gebärmutter.** *Zentralbl. Gynäkol.* 55(12): 1128-1132. 2 fig. 1931.—Systematic examination revealed occasional fat cells in the lateral portions of the uterus in almost every instance. In children (4 mos.-12 yrs.) the fat lay as in adults about the vessels in the parametrium but did not penetrate into the uterus, appearing there with sexual maturity. The author advances the hypothesis that the fat cells are transformation products of connective tissue cells.

8294. **MOORE, ROBERT A. The total number of glomeruli in the normal human kidney.** *Anat. Rec.* 48(1): 153-168. 1931.—The normal kidney of man from birth to 40 yrs. of age contains 800,000 to 1,000,000 glomeruli, with occasional values as low as 600,000 and as high as 1,200,000. There is no proof that postnatal nephrogenesis occurs in man. There is a senile loss of glomeruli in man, analogous to that in the rat. The total number of glomeruli in the 7th decade equals ⅔-½ the adult count. The 2 kidneys of 1 individual contain approximately an equal number of glomeruli.—*Author (courtesy Wistar Bibl. Serv.).*

8295. **REESE, J. D. Cyclic variation in certain osmiophile granules in the rat uterus.** *Anat. Rec.* 48(1): 55-63. 1 pl. 1931.—Treatment of the uterus of the rat by Bell's method of osmication revealed in the epithelium certain osmiophile granules, supposedly lipoid in nature, which show cyclic variation in size, number, and distribution. While the uterus is distended they are entirely absent. As the animal passes into the stage typified by a vaginal smear of cornified cells only, they first appear as a small cluster of fine granules at the base of the cell. They augment in size and number during metoestrum, and are most abundant during the early interval. There is a gradual diminution in the fat-content of the cell as dioestrum proceeds. This change does not appear to involve the uterine glands in the rat. There is a clear correlation between morphological variation and physiological activity, one being expressed in the disappearance of the fat-granules and the other in the distention of the uterus with fluid.—*Author (courtesy Wistar Bibl. Serv.).*

8296. **TEHVER, J., und E. VAU. Über das Vorkommen des Flimmerepithels in der Tube der Haussäugetiere während der Trächtigkeit und Brunst.** *Eesti Loomaarstlik Ringvaade (Rev. Vét. Estonienne)* 7(4/5): 168-176. 1 pl. 1931.—Preliminary contribution. During pregnancy ciliated epithelium is demonstrable in all parts of the uterine tube of sheep, cow, dog and cat. In sheep and cow, cilia are strongly developed in the ampulla but difficult to demonstrate in the isthmus. In the dog the ciliary lining of the tubes does not entirely disappear during oestrus.—*Authors' summary (transl.).*

8297. **TINKLEPAUGH, O. L., and ERNEST VAN CAMPENHOUT. The vaginal cell content of the mature and immature chimpanzee.** *Anat. Rec.* 48(2): 309-322. 2 fig. 1931.—The vaginal secretions of 2 ♀ chimpanzees have been studied cytologically to determine the histological changes occurring during the oestrous cycle. In the immature animal menstruation is accompanied by a marked drop in the amount of epithelial cells. Five different types of epithelial cells are described: clear, granular, intermediate, cornified cells, and scales; the last type is found only during the mid-interval. These types are similar to the various layers of cells in the epidermis. The vaginal discharge of the immature animal shows a high proportion of leucocytes and few epithelial cells. During the 5 successive months of observation there was a progressive increase in the number of epithelial cells and a decrease in leucocytes.

Besides clear epithelial cells, small vacuolated elements were found during the first part of that period; they progressively disappeared, and at the same time the distinction of the various types of epithelial cells began. The amount of mononuclear leucocytes is rather high at the beginning and decreases progressively with increase of the percentage of granular leucocytes.—*Authors (courtesy Wistar Bibl. Serv.)*.

ENDOCRINE SYSTEM

8298. CHRISTENSEN, KERMIT. Effect of castration on the secondary sex characters of males and females of Rana pipiens. *Anat. Rec.* 48(2): 241-250. 8 fig. 1931.—Complete castration in the adult ♂ has no distinct effect on the oviducts which are normally present in ♂♂ of this species, but it causes a reduction in the size of the seminal vesicles and in the development of the thumb pads. Complete spaying in the adult ♀ causes a most decided regression in size of the oviducts in comparison with those of controls. These results on the oviducts confirm embryological findings that in the ♂ of *R. pipiens* the oviducts are self-differentiating, but that in the ♀, after a period of self-differentiation, the further growth of the oviducts is under ovarial influence.—*Author (courtesy Wistar Bibl. Serv.)*.

8299. HINTON, J. WILLIAM. Histologic studies of the thyroid gland. I. *Amer. Jour. Surg.* 11(2): 269-279. 26 fig. 1931.—A study of sections of thyroid from 98 persons dying of accident, including 9 still born, 8 infants from birth to 2 yrs., 12 children 2-12 yrs. old, 7 adolescents 12-18 yrs. old, 60 adults 18-60 yrs. old, and old persons 75, 61 and 83 yrs. old, furnished no uniform histological pictures permitting conclusions as to what is normal thyroid tissue for different ages. The author concludes also that it will be necessary to consider the different types of goiter merely as stages of a continuous disease and not definite clinical entities.

8300. HOERR, NORMAND. The cells of the suprarenal cortex in the guinea-pig. Their reaction to injury and their replacement. *Amer. Jour. Anat.* 48(1): 139-197. 7 fig. 1931.—By the use of improved methods it was possible to show that the so-called dark and light cells of the zona reticularis in the guinea-pig's suprarenal are 2 types of senescent cells; cells degenerate either by cytolysis, chondriolysis, and karyolysis, or by shrinking of the cytoplasm, pyknosis, and chondriomegaly. Cells are continually dying off in the zona reticularis and are replaced by cells produced by cell division in the outer levels of the cortex, mainly between the glomerular and fasciculate zones. By causing an experimental toxemia in guinea-pigs by the injection of diphtheria toxin and by chloroform narcosis, the cell destruction and proliferation can be greatly accelerated. If the dosage is heavy, severe lesions, hemorrhages, and focal necroses may result. But if the lesions are not very severe, repair is usually effected within a month. The removal of the dead cells is brought about mainly by macrophages, plasma cells, and lymphocytes, coming in part from the blood stream and perhaps also from the endothelium and reticulum cells. There is evidence that the so-called siderophile substances are of no cytological significance, most often being an artifact due to poor fixation. Mitochondria were studied in all the layers of the cortex; they are usually rods and threads in the zona glomerulosa and granules in the rest of the cortex.—*Author (courtesy Wistar Bibl. Serv.)*.

8301. JACKSON, JOSEPH L. The shape and size of the human thyroid follicle in health and disease. *Anat. Rec.* 48(2): 219-239. 1 pl., 2 fig. 1931.—The material used consisted of 44 human thyroid glands, of which 10 were normal, 17 were glands of Graves' disease, 14 were glands of colloid goiter, 2 were glands of fetal adenoma, and 1 of carcinoma. A portion of each gland was used for histological section, and the remainder was cut into small cubes and macerated in 75% HCl, thereby isolating the follicles. Random samples were taken and the length and breadth of 500 follicles of each gland were measured under the compound microscope with an eyepiece micrometer. The shape was also noted. In order to obtain an accurate expression of these dimensions in the different clinical groups, 8 normal glands were combined so as to form a 1st group, 8 glands of Graves' disease to form a 2nd group, and 12 glands of colloid goiter to form a 3rd group. The average length of the normal follicle was 163.24 ± 1.17 μ; of the follicles of Graves' disease, 168.78 ± 0.678 μ, and of the follicle of colloid goiter, 244.5 ± 1.60 μ. On a basis of size and shape of the follicle, these groups could be differentiated from each other and also shape varied with age.—*Author (courtesy Wistar Bibl. Serv.)*.

8302. KOLMER, W. Quergestreifte Muskelfaser in der Pars infundibularis der Affenhypophyse. [Transversely striated muscle fibers in the infundibular portion of the ape hypophysis.] *Anat. Anz.* 71(19/20): 443-444. 1 fig. 1931.

8303. MILLZNER, RAYMUND J. The normal variations in the position of the human parathyroid glands. *Anat. Rec.* 48(2): 399-405. 1931.—Parathyroids are found on the anterior and lateral thyroid capsule in approximately 30% of all thyroids and on the true anterior thyroid capsule in approximately 10%. These percentages are based upon a study of both surgical and cadavar material and represent a constant variation in position, uninfluenced by such factors as the size of the thyroid gland or the type of disease present in a goiterous gland. These variations affect the inferior parathyroids more frequently than the superior in about the ratio of 2:1. Atypical arrangements of the thyroid vessels are usually associated with these variations in parathyroid position.—*Author (courtesy Wistar Bibl. Serv.)*.

8304. ONOZAWA, TAKEO. Quantitative Studie des Nebennierenmarks und -rinde beim erwachsenen Kaninchen. *Folia Anat. Japonica* 9(3/4): 183-199. 1931.—Examining the suprarenal glands of 27 adult rabbits by means of paper-cutting-and-weighing methods, the author found that: The weight of the gland, which is not always proportional to that of the body, averages 0.436 gm. and is 0.1982 gm. per kilogram of body weight. Its specific weight is 1.0371. The weights are greater in the ♀ than in the ♂. The left gland is usually larger than the right (frequency 77.8%), and its average overweighing percentage (14.7%) is greater than that of the right (4.0%). The volume of the medulla is not always proportional to the gland volume and to the body weight. Compared with the gland and the cortex, the individual variation of the medulla volume is very small. The medulla is, on an average, 3.16% of the entire gland volume. The average medulla volume, absolute and per kilogram body weight, is 0.0094 cc. and 0.0043 cc., respectively. The medulla is ordinarily larger in the larger gland of the two (frequency 71.4%). Accordingly, the medulla of the left gland is usually larger than that of the right (26.6%), its frequency being 64.2%. The gland-medulla-index in inversely proportional to the gland size. The cortex comprises, on an average, 96.84% of the gland. The cortex of the left gland is usually larger than the right.—*Author (courtesy Wistar Bibl. Serv.)*.

8305. PENITSCHKA, WILFRIED. Paraganglion aorticum supracardiale. *Jahrb. Morph. u. Mikrosk. Anat. Abt. 2, Zeitschr. Mikrosk.-Anat. Forsch.* 24(1/3): 24-37. 13 fig. 1931.—Studies on 3 fetuses in 6th mo., a newborn child, a 25 yr. old man; a full-term fetus and 2 adult hedgehogs (*Erinaceus europaeus*); an adult mole (*Talpa europaea*); a 3 mos. rabbit (*Lepus cuniculus*); an adult squirrel (*Sciurus vulgaris*); and a full-term guinea pig fetus (*Cavia cobaya*) showed a "paraganglion aorticum supracardiale" in the connective tissue between the aorta and the pulmonary artery, which corresponded in all important points with the carotid paraganglion. Like the latter its cells and cell nests were placed on and in a nervous reticulum containing ganglia and composed of sympathetic and cerebral nerves. Usually the cells did not stain with chromic salts. In this, these 2 paraganglia differ from the general sympathetic paraganglia whose principal properties are chromaffinity and

production of adrenaline. Both the carotid paraganglion, the extract of which as a rule did not increase blood pressure, and the supracardial paraganglion are located in the terminal area of the different "blood pressure regulators" ("sinus nerve" and "aortic nerve"). The assumption does not seem unfounded that they may participate in the action of these nerves.

8306. **STEIN, A. A. Experimentelle Untersuchungen über die Zellformen des interstitiellen Hodengewebes.** *Zeitschr. Wiss. Biol. Abt. B. Zeitschr. Zellforsch. u. Mikrosk. Anat.* 12(3): 483-517. 6 fig. (5 col.) 1931.—After injection of various doses of trypan blue the testis was examined in rats (killed 24 hrs. later), rabbits, cat, guinea pigs, rats after bilateral ligation of the vasa deferentia (killed 3 days-9½ mos. later), rats after unilateral ligation and extirpation of the opposite testis (killed 3 days-10.5 mos. later), rats after unilateral ligation (killed 12 days-8 mos. later), rats with unilateral castration but no ligation as controls, rabbits which had had daily doses of 0.5 g. cholesterol for 2-3 mos., and rats, rabbits and cats after inflammation of the testis from injection of turpentine (rabbits and cats killed 2 days, rats 2-23 days after injection). The principal characteristics which differentiated the interstitial cells (I.C.) from the histiocytes were: structure of the nucleus and the protoplasm; reaction to vital staining and inflammatory reaction. Lipoid and pigment inclusions were not strictly characteristics of the I.C.; in rats both were absent in the normal. Vital storage altered the form of the histiocytes, which appeared as rounded "mobilized" forms. Since the I.C. were indifferent to vital staining and to cholesterol they cannot belong to the reticulo-endothelial system. Ligation of the efferent spermatic duct quickly led to atrophy of the spermatic epithelium and increase in the amount of lymphatic fluid in the interstitial tissue. Atrophic changes in the tubules were followed by an increase in amount of the I.C. in the interstitial testicular tissue. Vitally stained histiocytes were increased after ligation of the efferent spermatic duct, yet present in considerably less amt. (in long continued experiments) than the I.C. which did not, however, store vital stains. The division of the I.C. was amitotic. With the beginning of regeneration in the seminal tubules the amt. of I.C. increased. In rats only a very small amt. of lipoid appeared in the I.C. after ligation of the efferent ducts and atrophy of the seminal epithelium. During atrophy there was a gradual increase in body wt., improvement of the fur, and increased libido in rats. After turpentine injection into the testicular tissue, large numbers of vitally stained histocytes and polyblasts, in addition to the leucocytes, assembled in the granulation tissue. In the region of the necrosis the I.C. increased in amt. and size, but did not store vital stains. In the acute stage of inflammation many I.C. died; in part, however, they were difficult to differentiate from the fibroblasts of the granulation tissue. In the later periods of inflammation in the testicular tissue, typical I.C. again appeared, which proceeded from cell forms similar to the fibroblasts. The interstitial cells were completely differentiated cell elements which were capable of no great change in the local action in rats.

BONES, MUSCLES, JOINTS, FASCIAE

8307. **BADER, LUIGI, e GIORGIO CANUTO. I canali di Havers in rapporto all'età. [Haversian canals in relation to age.]** *Arch. Antropol. Criminale, Psichiatria e Med. Legale* 50(2): 232-241. 1930.—In the tibiae of 18 subjects (21-70 yrs.), the authors found no increasing diameter of the Haversian canals in correspondence with increase in age (theory of Balthazard and Lebrun). The av. diameter of the canals in the 21-yr. subject (49.9 μ) would have indicated an age of 85 yrs. by Balthazard's rule, and the av. diameter in the 70-yr. subject (41 μ) would, by the same criterion, have indicated an age of 37-38 yrs.

8308. **BLAVET DI BRICA, CARLO. Esperimenti di innesti di cartilagine fissata nell'osso. [Grafts of fixed cartilage into bone.]** *Arch. Sci. Med.* 54(1): 63-70. 4 fig. 1930.—Cartilage fixed in alcohol and introduced into a defect in cranial bone in 6 guinea pigs remained for more than 1 yr. It was surrounded at first by connective tissue border attached to the grafted tissue on one side and to the bone on the other; later, by a more or less perfect capsule and strands of bone tissue penetrating into natural or artificial holes in the grafted cartilage. The fixed cartilage did not calcify as a whole, but some fragments of it which had become sequestrated in the proliferated connective tissue tended to do so.—*M. Comel.*

8309. **GRANT, J. C. BOILEAU. Interarticular synovial folds.** *Brit. Jour. Surg.* 18(72): 636-640. 8 fig. 1930.—Dissecting-room experience indicates that all movable joints normally have at all ages extensive interarticular synovial folds.

8310. **HAM, ARTHUR W. A histological study of the early phases of bone repair.** *Jour. Bone & Joint Surg.* 12(4): 827-844. 13 fig. 1930.—In experimental fractures 24 hrs.—28 days in age, in the rib and fibula of 12 rabbits, the adult bone cell is distinguished from the osteogenic cell which lines the bone in the periosteum, the Haversian canals, and the endosteum. The adult bone cell takes no active part in the process of regeneration following fracture. The osteogenic cells proliferate and differentiate into bone and cartilage. Concerning the controversy regarding the existence of a specific osteogenic cell, the subject of metaplastic bone formation is reviewed. The usual method of bone repair is through the agency of these specific osteogenic cells and not by the metaplasia of fibroblasts. Two factors, the presence of a local deposit of Ca salt and a good blood supply, are of great importance in effecting the differentiation of the osteogenic cell into bone. Cartilage results from the growth of osteogenic cells in the absence of these 2 factors. In the repair of fractures, bone and cartilage formation result from the differentiation of osteogenic cells in different environments.

8311. **LI CAUSI, GAETANO. Studi sulla regione lombare laterale: il trigono lombare laterale ed il tetragono lombare. [A study of the lateral lumbar region: the trigonum lumbale and the tetragonum lumbale.]** *Monitore Zool. Ital.* 40(11/12): 507-509. 1930.—The trigonum lumbale (Petit): A bilateral study of 77 bodies showed that it was present in 15.6%. In a majority of the cases a fibro-tendinous lamina extended from the lateral border of the latissimus dorsi, covered the trigone and became continuous with the fascia covering the external oblique muscle and finally inserted in the iliac crest. Beneath this lamina were found, as a rule, the internal oblique muscle and the aponeurosis of the transversalis and not infrequently the external oblique muscle laterally and the quadratus lumborum medially and in a deeper plane. Owing to this stratification and to the absence of foramina for vessels and nerves, hernia through the trigone cannot occur under normal anatomical conditions. The tetragonum lumbale (Grynfeltt) (studied on the same bodies) was present in 83% of the cases. It may assume various shapes, triangular, pentagonal, hexagonal but the most common form is the tetragonal with unequal incurving sides more appropriately termed a trapezoid. In this region the abdominal wall consists of a single fibrous layer, the aponeurosis of the transversalis, covered by the latissimus dorsi. On account of this arrangement and the presence of numerous foramina for vessels and nerves the predisposing anatomical factors for hernia are present. The tetragonum is frequently crossed by accessory bundles of the external oblique muscle subdividing it into secondary areas and occasionally completely obliterating it. Several cases of lipoma originating from the retroperitoneal and pararenal fat were observed protruding into the tetragone through the foramina for the vessels and nerves. This confirms the possibility that perirenal abscess spreading through these foramina may invade the intermuscular connective tissue of the lateral lumbar region.—*G. Li Causi (transl. by J. DeCarlo).*

8312. **MARQUORT, WALTER. Zur Histologie der Synovialmembran.** *Zeitschr. Wiss. Biol. Abt. B, Zeitschr. Zellforsch. u. Mikrosk. Anat.* 12(1): 34-52. 1930.—Microscopic examination was made of the elbow and knee of 8 adult and 2 young mice. The same joints of rabbits and dogs were also examined macroscopically. The synovial membrane was of a connective tissue nature; fibrillary, intercellular matter was seen; all cells had processes, so that the superficial cells were united to the deeper. The intima is thus to be considered a fibrocytic cell union in whose meshes the fibrillary intercellular substance is found; the occurrence of vessels passing through the membrane, covered only by a thin layer of intercellular substance, or lying free on the surface, indicate it is not epithelium. A further important argument for its connective nature is its vital staining with trypan blue: "The cellular transition of the synovial folds and villi showed storage increasing toward the interior of the joint. Here, too, the pronounced staining was undoubtedly made possible by the good vascular supply of the villi. The rest of the border of the interior of the joint was as strongly stained as this part." Neither histologically nor by vital staining was a sharp delimitation of the cartilage from the connective tissue of the synovial membrane possible. The cell-rich and cell-poor areas allow the possibility that during life such pictures of varying cell abundance arose by joint action. The abundance of cells in the region of the vessels was surprising. They were mostly histiocytic forms of adventitial cells, sometimes resting migratory cells with their lobed, cytoplasmic processes and free round cells. Yet the abundance of cells varied greatly in the various joints, which may be explained by the assumption that various conditions of irritation occur in the various joints.

8313. **MATWEJEW, D. N., und N. M. PAUTKIN. Die Gesetzmässigkeit im Bau des Schläfenknochens.** *Monatsschr. Ohrenheilk. u. Laryngo-Rhinol.* 64(8): 978-992. 8 fig. 1930.—From the temporal triangle it is possible to determine the position of the inner structures of the temporal bone by projection, since they all have a mathematical relationship to the triangle. The areas were determined within which lay the sulcus sinus petrosi superioris, the sinus sigmoideus, the bulbus venae jugularis, internal temporal artery, outer and inner auditory canals, facial nerves, semicircular canals, cochlea, fenestra ovalis, and fenestra rotunda.

8314. **MØLLER, JØRGEN. Le septum de Körner.** *Acta Oto-Laryngol.* 14(1/2): 213-220. 1930.—The development of the temporal bone from 2 different parts, the pars petrosa and the pars squamosa, involves the presence of 2 separate cell-systems, which, as shown in a series of 16 specimens, afterward may partially fuse together, but in most cases are distinctly separated from each other by the wall which Møller proposes to call the "septum of Körner."

8315. **MÜLLER, WALTHER. Über die Hemmung der Epiphysenverknöcherung unter dem Einfluss abnormer Belastung.** *Arch. Klin. Chir.* 162: 484-488. 3 pl. 1930.—In a large number of newborn rats, guinea-pigs and rabbits one hind limb was amputated at the knee. In the rat, unlike most other laboratory animals, a center of ossification in the head of the femur appears very late. After completion of growth the operated limb showed a well developed bony femoral head, while on the unoperated side no ossification was present in the head of the femur. This interference with the ossification of the epiphyses takes place only when the procedure is instituted while the epiphyses are still entirely cartilaginous.

8316. **NOPCSA, FRANZ. Über die Orientierung konvexo-konkaver Gelenkflächen.** *Anat. Anz.* 70(20/24): 401-416. 3 fig. 1930.—Such joints are classified as mesocoel when the concave surface looks toward the dorsal axis of the body, or as acrocoel when that surface looks towards the distal extremity of the appendages of the head (mandible), vertebral column (ribs), or trunk (limbs). Further they are classified as homotypic when the bones concerned are similar in form as in the metacarpo-phalangeal joints, or as heterotypic when they differ as in the shoulder and hip joints. A list is given of such joints as are known to be acrocoel or mesocoel and the conditions determining the occurrence of each type are discussed. 1. The joints of homotypic bones are permanently mesocoel. 2. Typical concavo-convex joints of heterotypic bones have no definite orientation. 3. Flat joints of this type may be transformed into mesocoel, in so far as their congruence permits. 4. Conversion of mesocoel into permanent acrocoel occurs only in the proximal carpal and tarsal joints of mammals (and some Theromorpha) and then only in association with a rotation of the arm or foot. Acrocoel joints between heterotypic bones may be explained on mechanical grounds and for such joints appear to be the more primitive type. Mesocoel joints between homotypic bones cannot at present be thus explained. In general it may be said that in all bones there is a tendency, originally perhaps individually acquired but later becoming hereditary, toward the formation of mesocoel joints, but this tendency is often suppressed in adaptation to the conditions of life.—*J. P. McMurrich.*

8317. **PETERS, NICOLAUS. Über eine Pseudoarthrose des Rothirsches.** *Zool. Anz.* 89(1/2): 62-64. 1 fig. 1930.—Description of a false joint (in a red deer) resulting from a gun shot fracture which did not knit, the ends developing callus and respectively concave and convex surfaces.

8318. **SANTOS, JOSÉ V. Changes in the head of the femur after complete intracapsular fracture of the neck: their bearing on nonunion and treatment.** *Arch. Surg.* 21(3): 470-530. 40 fig. 1930.—Of 14 cases of complete intracapsular fracture of the neck of the femur, in 6 the proximal fragment was nourished by the vessels of the ligamentum teres, and in 3 of these 6 cases reduction and fixation resulted in bony union. In 3 of the remaining 8 cases in which the head became necrotic, bony union was also obtained.

8319. **SHDANOW, D. A. Die Lymphgefässe des Tarsalgelenkes, des Kniegelenkes und des Hüftgelenkes des Menschen.** *Anat. Anz.* 69(7/12): 194-210. 5 fig. 1930.—100 joints were investigated by injecting Gerota's fluid into the cavity of the joint with the application of passive motions in the latter. The outflow of lymph from capsule and from cavity of the joints takes place through the same lymph vessels. The vessels are described in detail.—*From abstr. by D. A. Shdanow.*

8320. **SIGURDSON, LARUS ARTHUR. The structure and function of articular synovial membranes.** *Jour. Bone & Joint Surg.* 12(3): 603-639. 23 fig. 1930.—The structural histological studies were made on material from 6 fetuses aged 5-9 mos. and on bodies from the dissecting room (number not stated) aged mainly 50-80 yrs. Functional studies were made on animals, of which a cat, dog and an unspecified number of rabbits and guinea-pigs are mentioned. The inner surface of articular capsules is not formed by a distinct membrane, but by connective tissue modified as the synovial surface is reached. The cells here are more closely packed and the nuclei exhibit peculiar staining characteristics, but that does not seem to justify the use of the term membrane. The superficial synovial cells are not uniform in size or shape, some being quite small and round while others are large with branching processes. This type of cell is not confined to the surface. Synovial villi vary greatly in size and shape and are composed of connective tissue resembling the part of the capsule from which they arise. An excellent demonstration of variation in cell outlines on the synovial surfaces of articular capsules can be obtained by the use of Ag-impregnation methods. The intercellular substance is abundant, in contrast to that of the pleura and peritoneum; and the apparent cell outlines are much more irregular and do not resemble those of an endothelial or mesothelial layer. The presence of "stomata" in articular capsules is not confirmed. Carbon particles, when injected into the knee joints of guinea-pigs, evoke an inflammatory exudate in the joint

cavity, most marked on the 3rd day after injection. Some of these carbon particles are taken up by the lymphatic vessels and are deposited in the inguinal and lumbar nodes, while others are removed from the joint cavity by the action of phagocytic cells, some of which gain the lymphatic vessels while others remain in the subsynovial connective tissue for an indefinite period. Fe, in the form of ferric ammonium sulphate, disappears from joint cavities within 30 min. after injection by way of the lymphatics. I in the form of lipiodol diffuses slowly through the joint capsule, a period of at least 4 days being required for its complete removal, as judged by skiagrams. Immobilization of the tibiotarsal joints in rabbits over 53 days produced no marked structural changes in the joint capsule, but the amount of synovial fluid was considerably less.

ADENOID TISSUES

8321. ALTSCHUL, RUDOLF. Das Verhalten lymphatischer Organe bei Goldimprägnierung. *Anat. Anz.* **70** (18/19): 379-386. 3 fig. 1930.—In all preparations of lymphatic tissue the compact tissue is strictly "aurophobe," while the loose tissue reveals a distinct "aurophilia." The follicles of lymph nodes as well as the medullary cords, the malpighian bodies of the spleen, the tonsillar follicles, and the cortical substance of the thymic lobules remain unstained. On the contrary, the lymph channels of the lymph nodes, the splenic pulp, and the medulla of the thymus retain the Au reagent and appear darkly stained. The tonsils, which possess only the dense follicular tissue and do not contain a parenchyma rich in fluid, remain colorless. The conclusion is that it is the manner in which the tissue is arranged that determines the reaction, hence, a physicochemical condition and not a purely chemical state is involved.—*O. F. Kampmeier.*

8322. DABELOW, A. Reaktionsweisen des Lymphknotens beim Fetttransport. (Unter besonderer Berücksichtigung des Mesenterialknotens.) *Zeitschr. Wiss. Biol. Abt. B. Zeitschr. Zellforsch. u. Mikrosk. Anat.* **12** (2): 207-273. 23 fig. (15 col.). 1930.—Rats, mice, guinea pigs and 2 cats were given a fat diet, then killed after 1, 2 or 5 hrs. and the lymph glands examined in stained sections. During the absorption of fats the reticular cells of the mesenteric nodes become enlarged, proliferate both by mitosis and amitosis, store large amounts of fat and in many instances become free macrophages. The sinus endothelium reacts in much the same way. During starvation the cellular changes are largely reversed. There is proliferation of the germinal centers with feeding, while starvation may cause their complete disappearance. The passage of chyle may wash out many of the free cells and much of the fat. At times the intracellular fat is large during starvation. The passage of fat through the node changes its reaction to Sudan red and Nile blue. After injection of thyroxin the sinuses of the mesenteric nodes contained more fat and those of peripheral nodes less. Peripheral nodes showed no cellular changes during feeding.—*R. S. Cunningham.*

8323. FIESCHI, AMINTA. Ricerche sugli animali splenectomizzati. *Arch. Sci. Biol.* **13** (3/4): 341-352. 1929. —Researches were made on guinea pigs, 5-6 mos. after removal of spleen. Through vital staining with lithium-carmine an increased production of histiocytes is shown. Other elements, derived from reticulo-endothelial system, are found in the lymph follicles and in the trabecular framework of the medullary portion. In the splenectomized guinea pigs adrenalin caused, as in normal animals, leucocytosis with considerable lymphocytosis; therefore the spleen is not necessary for the induction of these changes.—*A. Jappelli.*

8324. LONGHITANO, A. Ricerche sul tessuto linfoide. Nota 2. Sulla struttura, funzione e rigenerazione delle linfoghiandole. [Studies on lymphoid tissue. 2. Structure, function, and regeneration of lymph glands.] *Sperimentale* **83** (4): 298-345. 9 fig. 1929.—Detailed histological studies on normal and pathological lymph nodes from various animals and man are given.—*Maud L. Menten.*

8325. MAMOLI, L. Il tessuto adenoide nella ghiandola lacrimale umana normale. *Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. e Nat.* **9** (1): 96-99. 1929.—Lachrymal glands were obtained from 15 operations and 16 post mortems. The ages varied from the 6th fetal month to 80 yrs. The cells of the lymphoid (adenoid) tissue are typical lymphocytes. The cells are arranged circularly around an area which resembles Flemming's germinating center. The lymphoid tissue is distributed about the periphery of the gland, the ducts, and the tubules.—*H. C. Stevens.*

8326. MENON, T. BHASKARA. Persistent thymus. *Indian Jour. Med. Res.* [*Calcutta*] **17** (1): 135-140. 1929. —Evidence is presented to show that a persistent enlarged thymus is found in a large proportion of cases of sudden death whether due to gun-shot wounds, fractures of the skull from accidents, multiple fractures of the ribs, subdural hemorrhage or chloroform anesthesia. In such medico-legal deaths, an apparent persistent thymus seems to be independent of the cause of death, but to be associated with the rapidity of it. The thymus has no causal bearing in these sudden deaths. Furthermore, death is so sudden that the gland has not had time to undergo atrophy or fat metamorphosis. According to the author's theory, chronic infections and protracted illness lead to atrophic changes in the thymus, acute infection to hyperplasia or no change at all, while sudden death has no influence on the gland. A possible interrelationship between the thyroid and the thymus is considered. Other theories of persistent thymus are discussed briefly.—*J. A. Dye.*

8327. SCATIZZI, IDA. La milza di "Tropidonotus natrix." [With French, English and German summaries.] *Arch. Zool. Ital.* **14** (2/4): 341-363. 1930.—In the connective tissue capsule of the spleen there are muscular, collagenous and elastic fibers. There is no clear distinction between white and red pulp, there being no follicles. The fixed elements of the pulp are represented by cells and a network of reticular fibers. The free elements are represented by lymphocytes, erythrocytes and leucocytes. Young lymphocytes and erythrocytes are found. Therefore in *T. natrix* the spleen has a lymphopoietic and erythropoietic function.—*Author's summary.*

8328. YOFFEY, J. M. Preliminary note on mammalian lymphoid tissue and its relation to the remainder of the haemopoietic system. *Jour. Anat.* **65** (3): 333-338. 1 fig. 1931.—The author assumes that all the blood cells are derived from cells closely resembling the small lymphocyte. He thinks the most probable course of events is that these cells are formed in lymphoid tissue, migrate to the bone marrow where they continue their maturation, and eventually return to the circulation as adult cells.—*R. S. Cunningham.*

PHYSICAL ANTHROPOLOGY

8329. BARBOSA SUEIRO, M. B. Annotations anatomiques. IV. Note sur l'hyperextension et l'hypo-extension du coude humain. [Anatomical Notes. IV. On the hyper- and hypo-extension of the human elbow.] *Arquivo Anat. e Antrop.* [*Lisboa*] **12** (1): 1-4. 1928.—In man and other mammals there is no relation between the hyperextension of the elbow and the existence of an olecranal perforation. The angle made by the axis of the ulna with the vector (flèche prolongée) of the sigmoid notch in normal human elbows varies from 115° to 125°; in cases with hypo-extension the angle was between 103° and 120°; and in cases with hyperextension it was over 128°. The position of the trochlea, with respect to the axis of the humerus, also causes variation of the amount of hyper- and hypo-extension.—*M. B. Barbosa Sueiro* (*transl. by J. P. McMurrich*).

8330. BLACK, DAVIDSON. Preliminary notice of the discovery of an adult Sinanthropus skull at Chou Kou Tien. *Bull. Geol. Soc. China.* **8** (3): 207-211. 9 pl. 1929. —The skull is apparently ♀, early adult or adolescent. There is remarkable development of the supraorbital

torus and crista sagittalis of the frontal bone. Frontal and parietal eminences are well-developed, the former exceeding that of *Pithecanthropus* to a marked degree. Parts about foramen magnum are not preserved in situ. The mastoid processes are of small size, yet massive; the left is somewhat the larger. The digastric fossa is relatively wide, long and deep. Crista supramastoidea is well-developed. The glenoid fossae are well-preserved on both sides; they are quite deep, and the post-glenoid processes markedly developed. A table of various measurements of hominid skulls is given with approximations for the *Sinanthropus* skull. *Sinanthropus* differs widely from *Pithecanthropus*, and is "a more generalized and progressive type." From its dentition, it probably is closely related to the common ancestor of Neanderthal man and *Homo sapiens*.

8331. **BONNEVIE, K. Recherches nouvelles sur les dessins papillaires des doigts humains. (Résumé des résultats.)** *Bull. Soc. Etude Formes Humaines* 7(3/4): 371-392. 1929.—"A short résumé of the main results, statistical as well as embryological, already published in previous papers (1923-29) with regard to the papillary patterns of human fingers."

Georg Thieme, Leipzig. 1929. M. 41.

8334. **LOTH, E. Leçons d'anthropologie des parties molles (muscles, intestins, vaisseaux, nerfs périphériques).** *Bull. Soc. Morph.* No. 1/2. 53p.; *Bull. Soc. Etude Formes Humaines* 7(1/2): 82-132. 1929.—A series of lectures on the anthropology of the soft parts. After a short historical introduction, and a discussion of different categories of variations, and after defining the terminology of the subject, the author dealt with the muscles of the face, neck, trunk, upper and lower extremities, the alimentary and respiratory tracts, the genito-urinary apparatus, the vascular system, and the peripheral nerves. This represents the first attempt at the systematic treatment of these problems from the point of view of racial differences.—*E. Loth.*

8335. **NIPPERT, OLGA. Zur Morphologie der lateralen Orbitalwand.** *Verhandl. Schweizer. Naturforsch. Ges.* 110: 184-187. 1929.—The paper aims to collect the variations that recall the original unity of the orbit and the temporal fossa in Primates and especially in the various races of man. Author presents a statistical study of the width of the inferior orbital fissure, the number of zygomatic-temporal foramina, the perforations of the lateral wall and the intercalated bones along the sutures. —*O. Schlaginhaufen (transl. by R. F. Shaner).*

8336. **PARSONS, SUSANNE R. A statistical study of the incidence of contracted pelves in Chinese women and its relation to labor and the size of the newborn.** *Amer. Jour. Obstet. & Gynecol.* 18(3): 419-423. 1929.—Average pelvic measurements of 500 Chinese women delivered spontaneously in Shanghai fell below the usual white standards. 49.8% of the pelves were abnormal, nearly ⅔ of total pelves were funnel type. No rachitic or flat pelves occurred in this series. The babies were smaller than white babies. Comparing Chinese pelves with those of women (negro and white) in Baltimore, there were 13.66% contracted pelves in white women; 43% in negroes; 49.8% in Chinese and 9.2% in North American Indians.

8338. **PIJPER, ADRIANUS. The blood-groups of the Bantu.** *Trans. Roy. Soc. So. Africa* 18(4): 311-315. 1930. —Examination of 880 Bantu from all parts of the Transvaal, mostly patients in hospitals and clinics, was made by the test-tube method. 53.2% were O, 25.3% A, 19.2% B, and 2.3% AB. The index is 1.3. Of the subjects, 705 were Basuto, 64 Matabele, 47 Shangaan, 22 Zulu, 14 Swazi, and the Kosa, Bavenda, and Baralong tribes were represented. In the Basuto, distribution of the blood groups was about the same as in the total population. The high index (that of African negroes being below 1.0 and of American negroes 1.3), is considered, and leads the author to believe that the Bantu are "direct descendants of the Hamitic race, with perhaps a very slight admixture of negro blood."

8339. **PRATJE, ANDREAS. Die Anwendung stereoskopischer Methoden in der Anthropologie. [Application of stereoscopic methods in anthropology.]** *Zeitschr. Ges. Anat. Abt. 1. Zeitschr. Anat. u. Entwicklungsgesch.* 89 (4): 467-493. 6 pl., 15 fig. 1929.—Bones and most soft parts can be accurately measured through the use of a stereometer.—*A. Pratje (transl. by S. A. Weisman).*

8340. **SCHEIDT, WALTER. Annahme und Nachweis von Rassenvermischung.** *Zeitschr. Morphol. u. Anthrop.* 27(1): 94-116. 3 fig. 1928.—The author gives a critique upon the obscurity of usual race definitions, and he suggests the elimination of notions of "pure race," "race mixture," and "folk mixture" previously selected by the author in race definitions. Methods followed: Critique on the dispersion of masses for the determination of folk mixture and on the importance of the correlation of characters. One seldom expects genetic components in folk mixture. The grade of mixture is dependent upon circumstances and is influenced by assortative mating. The author proposes an "index of assortative mating." Evidence of partial folk mixture gives an "index of type variation," but above all, rarely, the indication of correlation of characters.—*W. Scheidt (transl. by R. B. Bean).*

8341. **SCHLAGINHAUFEN, OTTO. Die anthropologische Untersuchung an den schweizerischen Stellungspflichtigen, III. Bericht, 1929.** *Verhandl. Schweizer. Naturforsch. Psychiatr.* 119(4): 613-630. 1929.—Height does not characterize the infantile gracile type, but tall individuals may be found in the group. The essential features are gracility of build and child-like appearance such as smooth and tender skin and small bones. Tall individuals of similar appearance do not differ psychically from the small individuals belonging to this group. Graceful motions, vivid and changing but child-like facial expression are suggestive of the preponderance of extrapyramidal factors. The type is characterized particularly by its psyche, childish opinions and interests, superficiality, lability of emotions, accentuated suggestibility, and inclination to hysterical reactions. These peculiarities have been characterized by the term "hysteroid." The hysteroid character of individuals of the infantile gracile type justifies the conception that hysteria expresses a retardation of development on a more child-like level.—*M. A. Goldzieher.*

8344. **THOORIS, A. La morphologie de l'athlète.** *Rev.*

Antrop. [*Paris*] 39(10/12): 364-375. 7 fig. 1929.—The quadrupedal position favors the study of the proportions of the model and of the mimic. Athletes are short or tall (brevilinear or longilinear), round or flat (the former more massive, the latter more slight), they have more of form than function (preponderance of trunk) or more of function than form (preponderance of limbs). The principles of morphology are applicable to the diagnosis of athletic aptitudes and to the choice of specializations, by utilizing the segmental predominances.—*A. Thooris* (*transl. by J. P. McMurrich*).

8355. **GLASUNOW, M. Beobachtungen an mit Trypanblau vitalgefärbten Meerschweinchen. III. Der Entfärbungsprozess.** *Zeitschr. Wiss. Biol. Abt. B, Zeitschr. Zellforsch. u. Mikrosk. Anat.* 12(2): 365-381. 1930.—In 16 days each of 7 guinea pigs received 18 cc. of 1% trypan blue; they were killed 4, 10, 20, 30, 40, 70, and 160 days thereafter and the liver, spleen, cervical lymph nodes, kidneys, lungs, and connective tissue examined. In 4 days the hepatic cells, most of the Kupffer cells, and the cells of the biliary ducts were stained; the endothelium of the vena centralis contained only a little stain; some histiocytes in the interlobular connective tissue were also stained. All the kidney except the descending limb and the arched collecting tubules was strongly pigmented and these 2 slightly so. The dye was uniformly and abundantly present in the tissues of the lungs. The pulp cells of the spleen contained a large amt., only occasional reticular cells were stained, and there was almost no color in the endothelium of the sinuses. Both cortex and medulla of the lymph nodes contained many stained cells. The fibrocytes and histiocytes of the cervical connective tissue contained much dye, the endothelium of the vessels usually none. By the 160th day occasional blue vacuoles were present in the epithelium of the large biliary ducts and the fibrocytes of the interlobular connective tissue, but none in the hepatic or Kupffer cells. Dye was present only in the large collecting tubules and papillary ducts of the kidneys. In the lungs it was faintly noticeable in a few dust cells only; the spleen and the lymph nodes contained no pigment. Some of the fibrocytes and none of the histiocytes contained pigment. Decoloration occurred very irregularly. The dye was usually given up to the fluids surrounding the cell, the physical condition playing a large rôle, for dye in solution disappeared more quickly than that precipitated. One can assume 2 principal factors in decoloration: the proximity of the blood and the current passing through the cell. The internal characteristics of the cells also participated, for the histiocytes decolorized more quickly than the fibrocytes; to these also must be attributed the color changes in the reticulo-endothelial cells (blue to yellowish-brown or black), which, since no Fe reaction was obtained, must have occurred by intracellular splitting of the dye. Apparently there was a more or less general rule that coloration and decoloration are proportional.

8358. **KUBIE, LAWRENCE S., and DAVID DAVIDSON. The ammoniacal silver solutions used in neuropathology. Their staining properties, chemistry and methods of preparation.** *Arch. Neurol. & Psychiatry* 19(5): 888-903. 1928.—The ammoniacal Ag solution which is prepared from $AgNO_3$ and NH_3 alone is spoken of as the solution of "ammoniacal $AgNO_3$," with Na carbonate and NH_3 as "ammoniacal Ag carbonate," and with NaOH and NH_3 as "ammoniacal Ag hydroxide." The ammoniacal Ag ion which is formed in the 3 methods used for preparing Ag staining solutions is constant in formula, $Ag(NH_3)_2^+$. The activity of this ion varies in sensitivity, stability, rate and intensity depending on the ions with which it is associated. The ammoniacal Ag hydroxide, because of its extremely high hydroxyl ion concentration, is the most unstable—that is, it reduces most rapidly with tissue elements. The ammoniacal $AgNO_3$ solution is most "stable." The ammoniacal Ag carbonate solution is intermediate between the other 2. The ammoniacal $AgNO_3$ solution is only rarely useful. For most purposes, the ammoniacal Ag carbonate solution, because of its greater stability and its somewhat slower action, is more easily handled. Methods for preparing these solutions are described.—*From authors' summary.*

Phys. et Path.* 7(7): 237-239. 1930.—This modification of Mayer's muchematin stain consists essentially in increasing the Al chloride to 5% and after 24 hrs. adding just enough NH_4OH to be completely used in precipitating Al hydrate.—*J. G. Sinclair.*

8363. **PENFIELD, WILDER. A further modification of del Río-Hortega's method of staining oligodendroglia.** *Amer. Jour. Path.* 6(4): 445-447. 1 pl. 1930.—The method (called Dockrill's modification of the silver carbonate method for oligodendroglia) is particularly reliable for staining the spinal cord, brain stem and cerebral white matter, where other methods are often less successful, and the oligodendroglia of the retina, nerve head and optic nerves.

8364. **POLICARD, A. Sur la fixation de poussières minérales dans le poumon humain.** *Bull. Histol. Appl. Phys. et Path.* 7(10): 337-353. 3 fig. 1930.—The method of studying sections in gelatin or water permits identification of many dust particles by refractive differences not apparent in balsam. Concentrated 50-60% perchloric acid placed in a drop on the section with precautions against explosion will destroy the organic matter completely, liberating lipoids progressively as it spreads. These may be identified to some degree. Inorganic particles and carbon dust of various kinds are left but their position is disturbed in the reaction. The same method may be applied to bits of lung in a test tube and centrifugal sediment may be tested optically and microchemically. No method is at hand for organic dust or ultramicroscopic dust. The dust is deposited among the connective tissues by phagocytes which later disappear. The process is a mild reaction which may, if intense, verge onto the pathological.—*J. G. Sinclair.*

8365. **POPOFF, NICOLAS. La méthode des colorations en masse appliquée à l'histologie normale.** *Bull. Histol. Appl. Phys. et Path.* 7(9): 300-302. 1930.—Small pieces 3-4 mm. thick are soaked 12-24 hrs. in dilute hemalum; may be left 10 days at 30-35° C. Wash in running water at least 10 min. Rinse in distilled H_2O and stain in 0.5% alcoholic eosin or erythrosin 6 hrs. Dehydrate in eosin alcohols 80% up, rinse in 3 changes absolute alcohol, clear, and embed.—*J. G. Sinclair.*

8366. **SCHMID, HARALD. Über physikalische Beeinflussung der vitalen Farbstoffspeicherung.** *Jahrb. Morph. u. Mikrosk. Anat. Abt. 2, Zeitschr. Mikrosk.-Anat. Forsch.* 23(1/2): 1-8. 4 fig. 1930.—After intravenous injection of trypan blue, diathermy was applied bitemporally to the head in rabbits for 10-15 min. at 0.1 amp. In comparison with controls, there was an increase in dye in the choroid plexus and in histiocytes carrying the dye. In the epithelial cells it was present in droplets between the nucleus and the periphery, not as fine dust. Diathermy very probably increased the permeability of the plexus portion of the blood-spinal fluid barrier as seen from colored spinal fluid in moderate staining; the concentration of dye remained at a minimum, however, so that no signs of nervous irritation appeared.

UNCLASSIFIED

8367. **BLECHSCHMIDT, E. Zur Anatomie des Subkutangewebes.** *Zeitschr. Wiss. Biol. Abt. B, Zeitschr. Zellforsch. u. Mikrosk. Anat.* 12(2): 284-293. 10 fig. 1930.—Frozen sections of the subcutaneous tissue (breast, buttock, abdominal wall, thigh) were stained heavily with methylene blue, bringing out the reticular structure for gross morphological study.

8368. **DAUVART, ANNA. Über die zyklische Gewichtsvariation des Vorderbeinskelettes des Frosches.** *Zeitschr. Wiss. Biol. Abt. D, Roux' Arch. Entwicklungsmech. Organ.* 122(1): 140-151. 2 fig. 1930.—In a previous article the author had studied seasonal variations in the weight of the bones of the foreleg of the ♂ frog. In this study data of such variations in 89 ♀ *Rana temporaria* and 46 *R. esculenta* var. *ridibunda* are compared with the previous figures. The conclusions are: The greater seasonal variation in weight of the bones of the foreleg of the ♂ frog than in that of the ♀ constitutes a typical cyclical secondary sex character. Comparison of the mean of the relative weights (always based on weight of femur + tibiofibula) of the bones of the foreleg of *R. temporaria* ♂ in spring and autumn shows that the spring mean (taken as 100) is about 10% greater than the autumn mean, but in the ♀ the difference is only 5%. This relation of means in *R. esculenta* ♂ resembles that in *R. temporaria*, but the ♀ shows an even smaller difference (4.2%) than the *R. temporaria* ♀. The mean of the relative weight of the bones of the foreleg of *R. temporaria* ♀ in spring reaches 70% of that of the ♂♂. In *R. esculenta*, it is 81.7%. Since in both species the comparison of seasonal differences in the ♂ with those in the ♀ shows a smaller ratio when expressed in percents than is the case with the means, the sex difference in the extent of seasonal variations must not be regarded as the direct expression of absolute weight differences (in the bones of the foreleg). The condition of the different development of seasonal variation in the 2 sexes of these frogs expresses rather precisely the same condition that is met in many other vertebrates, when a sex character strongly developed in the ♂ appears also in the ♀ sex even though to a lesser degree.—*Author's conclusions (transl. by A. M. Boring).*

Biol. Sperim.* 5(2): 127-130. 1930.—The morphological constitution of the reticular stroma in living tissues was studied in very thin sections of fresh organs of rat kept in protracted fasting, the cuts being immersed in Ringer's solution. This method allowed a clear observation of the particularities of the

reticular stroma in liver, kidney, alimentary canal, heart, etc.—*M. Comel.*

8370. **MENNER, ERICH.** Über die Stützelemente in der Retina der Wirbeltiere. Zugleich eine Erwiderung auf die Arbeit von E. Murr in Band 10, Heft 2 Dieser Zeitschrift. *Zeitschr. Wiss. Biol. Abt. B, Zeitschr. Zellforsch. u. Mikrosk. Anat.* 11(2): 414-428. 4 fig. 1930.—The assumption of Murr (see next entry) that it is not in accord with the facts that the limitans externa is not to be recognized in the eyes of various animals is refuted. An external limiting membrane does not in fact exist. The limitans externa is rather a portion of the supporting cells of the retina, never an independent structure. The supporting cells exhibit as many spaces upon their scleral aspect as there are visual elements present so that it would be better to call this border the limitans reticulata externa. If thick sections of 20 or more μ are examined as in Murr's investigation, a "membrane" is simulated, while in thin sections of 2.5-5 μ, the limitans reticulata externa does not appear.—*E. Menner (transl. by T. J. Putnam).*

8371. **MURR, ERICH.** Zur besseren Unterscheidung von Stäbchen und Zapfen in der Retina der Wirbeltiere. *Zeitschr. Wiss. Biol. Abt. B, Zeitschr. Zellforsch. u. Mikrosk. Anat.* 10(2): 386-393. 1930.—Recently the difference between the nuclei of the visual cells has been recognized in vertebrates of almost all classes and has been employed as an indicator of the morphological duplicity of the visual cell layer in all cases where differentiation between rods and cones is difficult. A preliminary study of further cases reveals that while no statement has been proven concerning physiological duplicity, it seems possible in all cases of morphological duplicity of the nuclei to determine accurately a morphological duplicity of receptive external processes of the visual cells. The missing external limiting membrane could be demonstrated in all cases investigated and, at least in the cat, cones were also exhibited.—*E. Murr (transl. by P. A. Moody).*

Roma* 56(10): 305-313. 1 fig. 1930.—In view of its coagulating property the author finds that aqueous humor of second formation is an excellent and easily prepared culture medium for tissues in vitro.

8376. **WILSON, GORDON.** The utriculo-endolymphatic "valve." *Acta Oto-Laryngol.* 14(1/2): 276-282. 4 fig. 1930.—In the series of sections described, the striking appearance of the utricular fold, or "utriculo-endolymphatic valve," tends to support Bast's view that so definite a structure should have a definite function. Since, presumably, the usual movement of endolymph must be slow, possibly such a mechanism may, under conditions of sudden pressure-change, prevent abrupt fluid changes in the utriculus. The "valve" in this series is a much stouter structure than the thin epithelial vesicle against which it lies, and there is, it seems, no substantial wall to complete the valvular mechanism—unless it be assumed that the perilymph serves as a liquid support for the utricular wall.—*From author's summary.*

The authors obtained, as in homoplastic grafts, positive results in the union of the optic vesicles of *R. esculenta* with those of *Triton;* of the brain of *R. esculenta* with the eye of *Triton;* of olfactory placodes of *R. esculenta* with those of axolotl. The authors also discuss the destructive processes which the heteroplastic transplants meet, as the host, having terminated its embryonal development (vitelline absorption), enters larval life; because only then new humoral relations are established (Cotronei) and, therefore, a new biochemical aspect exists. The authors also record a case of union, via an optic nerve, between the transplanted eye of *Bufo vulgaris* and the brain of axolotl.—III. Anlagen of the eye, of the olfactory

placode, and of the brain of embryos of *Triton*, transplanted to embryos of *Rana esculenta* or *Bufo vulgaris*, are rapidly destroyed shortly after the operation. This embryonal destruction differs from the larval destruction in the inverse transplants (described above) since in the former, the host immediately shows itself incompatible with the transplants, thus stopping their differentiation; while in the second case, the host becomes incompatible only when it has reached the end of embryonal development and is entering the larval stage. This has permitted a differentiation in the anlage of the transplanted organs. This embryonal incompatibility has not held true when anlagen of *Triton* have been transplanted into embryos of *Hyla arborea*, thus showing how, among related forms (various species of Anura), profound differences in biochemical constitution may exist.—*G. Cotronei* (*transl. by G. A. Bica and T. T. Job*).

8380. **DROOGLEEVER FORTUYN, A. B. (edited by).** A catalogue of the first 400 specimens of the human embryological collection in the Department of Anatomy of the Peking Union Medical College. *China Med. Jour.* 41(2): (Anat. Suppl.) 1-94. 11 pl. 1927.—The material was collected between 1919 and 1925 and includes specimens of the white race, Korean race, mixed races, and 2 Manchus but the majority (356) are Chinese, from various provinces. Protocols are given in a table supplemented by notes on special points and on methods. The Chinese material is divided into 2 groups. The normal group is analyzed for increase in weight (2 curves) and for age determination. The factors considered in the latter are, hair, finger nails, genitalia, separation of fused eyelids and disappearance of nasal plug. Specimens were examined for Mongolian spot, but it was concluded that since bluish discoloration occurring in the sacral region is often like that in all surface hollows, the skin of dead fetuses is unfavorable for the study of skin pigmentation. The pathological Chinese series is classified with brief discussion of the principal anomalies.

8381. **DUBINKIN, G., und A. MOTNENKO.** Über die Entwicklung der Menisken des Kniegelenks. *Arch. Klin. Chir.* 165(3): 539-552. 8 fig. 1931.—Examination of the meniscus in 16 fetuses (premature and mature) 9.5-71 cm. long showed that in the first the knee joint meniscus was barely indicated, in the last it was fully developed (about 2nd month post natal life).

8382. **FOLEY, JAMES O.** The cytological processes involved in the formation of the scalae of the internal ear. *Anat. Rec.* 49(1): 1-13. 2 pl. 1931.—In the pig embryo, as contrasted with human, the scala vestibuli slightly precedes the scala tympani in time of appearance as development progresses from basal to apical turns of the cochlea. Cytologically, the first step in the formation of the scalae is an enlargement of the mesenchymal spaces. Cavities thus initiated coalesce to form still larger areas. The initial process seems to consist of liquefaction accompanying attenuation, separation, and retraction of the mesenchymal strands, but this is soon followed by visible degeneration of these strands and the removal of granular débris by connective-tissue macrophages. The scalae thus enlarge through destruction of the mesenchyma. Measurements of the growing cochlea show that, during the period in which the initial formation of the scalae takes place, there is less growth in the main axial and basal planes than at any subsequent or preceding period. Therefore, it is believed that mechanical growth stresses play an insignificant part in the early formation of the periotic spaces. Indeed, the evidence obtained by other authors from experimental removal of the otocyst suggests that the degenerative changes that occur at the site of the periotic spaces and that initiate the formation of the scalae, as described in this article, arise in response to factors resident in the membranous labyrinth.—*Author* (*courtesy Wistar Bibl. Serv.*).

8383. **FUKUDA, YOSHINOBU.** Beiträge zur Entwicklungsgeschichte und Morphologie des Laryngotrachealskeletts von Megalobatrachus japonicus. *Folia Anat. Japonica* 9(2): 169-181. 1931.—The anlage of the laryngotracheal skeleton first appears in 20-mm. larvae on either side of the larynx as a rod-shaped body, the primitive arytenoid, which later sends from its lateral margins the slight processus muscularis. In 30-mm. larvae the pars arytaenoidea prolongs caudodorsally as the pars trachealis. In 80-mm. larvae the pars trachealis has been greatly elongated and fuses dorsally in its cranial part with that of the opposite side, forming the pars cricoidea. The whole cartilago lateralis now is composed of fibrocartilage, while the ventral part of the pars arytaenoidea and the caudal part of the pars trachealis show the character of juvenile hyaline cartilage. The pars arytaenoidea forms ventrocaudally the processus vocalis. In 179-mm. larvae the cartilago lateralis consists of the pars arytaenoidea, pars cricoidea, and pars trachealis. All these parts are connected with one another. The greater part of the ventral portion of the pars arytaenoidea and the caudal part of the pars trachealis have been differentiated into typical hyaline cartilage, the former gives off dorsocaudally the processus trachealis.—*Author* (*courtesy Wistar Bibl. Serv.*).

8384. **HARTMAN, CARL G., WARREN H. LEWIS, FRED W. MILLER, and W. W. SWETT.** First findings of tubal ova in the cow, together with notes on oestrus. *Anat. Rec.* 48(2): 267-275. 1 pl. 1931.—The first was in the 2-celled stage, removed 48 hrs. after mating. It measured in the living state 135.5 × 135 μ, inside zona, which was 15 μ thick. The egg refused to divide further in blood plasma. The 2nd egg, unfertilized, was removed 72 hrs. postcoitum. Of this egg the inside diameter of the zona was 145 × 140 μ. Photographs of the eggs taken in the living state are included in a plate. At 48 hrs. the uterine horns contained a thick viscid fluid with a pH of 9; at 72 hrs. this mass had been expelled into the vagina, and the meager uterine fluid had a pH of 7. A 3rd cow had not ovulated 72 hours postcoitum. The reproductive history of the 3 cows, including their oestrous cycles, is given.—*Authors* (*courtesy Wistar Bibl. Serv.*).

8385. **HILL, J. P., and J. FLORIAN.** The development of head-process and prochordal plate in man. *Jour. Anat.* 65(2): 242-246. 1 fig. 1931.—Study of a young human embryo (Dobbin embryo, 960 μ long) supports the conclusions that the head-process, which arises as a forward growth from Hensen's knot and is accompanied by forward extensions of the primitive streak mesoderm, becomes distinguishable during development (embryos "Dobbin," "Rossenbeck," "Ingalls") into 2 portions, a caudal part which early assumes the form of a typical chorda-canal and a cranial part which undergoes differentiation in the caudo-cranial direction into a median chorda-process (later transforming into a chorda-canal) and 2 lateral mesodermal bands ("gastral or archenteric" mesoderm). In all the stages studied the head-process passes into continuity at its cranial end with the mesoderm of the prochordal plate. Those stages have furnished no definite evidence of a participation of the prochordal plate in the formation of the chorda-canal.

8386. **LEIRI, F.** Über die Knorpelfuge vor dem ovalen Fenster. *Acta Oto-Laryngol.* 15(1): 74-84. 5 fig. 1931.—Study of 3 embryos (of 3, 5 and 6 mos.) convinces the author that, contrary to Eckert-Möbius, the formation of the synchondrosis found in the fetal labyrinth capsule from the 5th mo. on (and sometimes later in the form of the postembryonic cartilaginous rests) is not dependent on the presence of vessels; these do not precede but follow the laying down of the cartilage.

8387. **MOOKERJEE, HIMADRI KUMAR.** On the development of the vertebral column of Anura. *Phil. Trans. Roy. Soc. London B* 219(465): 165-196. 5 pl., 3 fig. 1931.—*Rana temporaria, Bufo melanostictus, Bombinator igneus* and *Xenopus laevis* are chosen as different types. The centrum is formed by a part of the perichordal tube formed by the skeletogenous layer which is very thin in the vertebral region, so that apparently the dorsal arcualia rest directly on the sheath of the notochord.

Intervertebral bodies are a part of this perichordal tube. There is no justification for dividing the intervertebral body into interdorsal and interventral. The intervertebral body divides into two as condyle and socket by the migration of a strand of connective tissue cells, the direction of which determines the nature of the vertebra, viz., the procoelous or the opisthocoelous type. As the centrum is not formed from the dorsal arcualia, the original types of formation of centrum and its classification cannot stand, viz., the epichordal and the perichordal types. In the first 2 types, the whole of the perichordal tube chondrifies and ultimately ossifies. In the latter 2 types, the dorsal portion of the perichordal tube chondrifies and ossifies, the rest degenerates into a membranous state. In *Xenopus laevis* there is a rectangular-shaped cartilage, formed by the chondrification of the mid-ventral portion of the perichordal tube throughout the whole of the vertebral column, which degenerates ultimately. Between the occipital arch proper and the atlas arch proper, there is an intercalated arch, the division of the 2 limbs of this arch forms the occipital condyles and the cups of the atlas. In *Bombinator igneus* and *Xenopus laevis* the 2nd, 3rd and the 4th vertebrae have long transverse processes which are formed not only from the transverse processes proper, but also from a fusion of the ribs, which lose their identity with ossification. In each of the 4 cases, viz., *Rana, Bufo, Bombinator* and *Xenopus,* the transverse processes of the 9th vertebra articulate on the side of the ilium a little below its tip.—*H. K. Mookerjee.*

8388. PANKRATZ, DAVID S. The development of the suprarenal gland in the albino rat, with a consideration of its possible relation to the origin of foetal movements. *Anat. Rec.* 49(1): 31-49. 12 fig. 1931.—The suprarenal gland in the albino rat appears first in the 13-day-old fetus. A slight thickening of the coelomic epithelium medial to the cephalic portion of the mesonephros marks the anlage of the suprarenal cortex. Growth at the time is rapid, and during the 15th-16th days the cortex forms an oval mass protruding into the dorsal coelomic cavity. About the 16th day, just before fetal movements begin, cells migrate from sympathetic ganglia toward the cortex. At the time (16 days or more) when fetal movements have been first observed by Swenson and by Angulo, a definite mass of sympathochromaffin cells is located among the medial cell cords of each cortex. This cell migration continues during the 17th and 18th days and possibly till birth. In the 17-, 18-, and 19-day fetuses nerve fibers which connect the gland with the sympathetic chain are observed with large ganglionic cells along their course. From the literature on different phases of suprarenal development and appearance of fetal movements in the chick, mouse, rabbit, cat, and man, the author concludes that in these animals a coincidence in development of gland and fetal movements exists similar to that in the rat.—*Author (courtesy Wistar Bibl. Serv.).*

8389. PATTEN, BRADLEY, M. The embryology of the pig. 2nd ed. 327p. col. frontispiece, 168 fig. (2 col.) P. Blakiston's Son & Co.: Philadelphia, 1931. Pr. $3.50. —The subject matter of this book is not essentially different from that of the 1st edition except for the inclusion of original data connected with the changes in the mammalian circulatory system at or near birth. The work is primarily a text for students with some zoological background, presumably including a course on the embryology of the frog and chick. The first chapter is a foreword to the student on the significance of the subject, particularly for those engaged in the study of medicine, while the second deals with the reproductive organs of the adult ♂ and ♀ pig, gametogenesis, sex-determination, and ovulation. Following this is a chapter on the sexual cycle and fertilization. This serves to introduce the definitely embryological phase of the subject, which begins with a discussion of cleavage and the origin of the primary germ layers. Following this is a chapter on the early development of body form and the establishment of the organ systems, and another on the extra-embryonic membranes and the relation of the embryo to the uterus. The external appearance of a pig of 10 mm. C. R. length is then taken up, together with a description of the condition, at this stage, of each of the organ systems whose origin was previously noted; there are separate chapters devoted to the further development of each of these systems. The histogenesis of bone, and the development of the skeleton, face and teeth are given special treatment in the last 2 chapters as particular illustrations of certain general cytological activities and method of differentiation.—*R. S. McEwen.*

8390. PECK, SAMUEL M. The melanotic pigment in the skin, hair and eye of the gray rabbit: its embryologic development and the question of the mesodermal origin of epidermal melanoblasts. *Arch. Dermatol. & Syphilol.* 23(4): 705-729. 14 fig. (3 col.) 1931.—Melanin formation began in the epidermis and hair matrix cells of the bulb in the 85-mm. embryo, while the cutis and papillae were entirely free from pigment. Pigment formation was autochthonous in the ectodermally derived melanoblasts of the epidermis and hair; the mesoderm played no part in this process. Del Rio-Hortega's conclusions about the mesodermal origin of the melanoblasts of the epidermis and hair were based on misinterpretations. The melanoblasts which seemed to lie in the cutis, and which he assumed to be mesodermal elements, have been shown to be peripherally situated melanoblasts belonging to the follicular epidermis and upper epidermal hair sheets. The Dopa reaction became positive with the beginning of pigment formation in the melanoblasts of the skin, hair, and eye. It was the 1st evident step in the process of pigmentation, and its duration and intensity were an index of the degree of pigment formation. From the beginning of pigment formation and throughout its active stages, the dendritic melanoblasts were much more numerous than the nondendritic ones; at the height of pigment production nearly all of the melanoblasts showed a dendritic form. The old pigment was cast off with the scales. Chromatophores did not take part in this process in the pigment formation described. —*Author's conclusions.*

8391. SONDERMANN, R. Beitrag zur Kenntnis der Entwicklung des Kammerwinkels und der angrenzenden Organe. *Graefe's Arch. Ophthalmol.* 126(1/2): 173-202. 29 fig. 1931.—Eyes, usually in serial sections, from about 140 human fetuses showed that the first anlage of the iris, the trabecula, and Brücke's ciliary muscle is uniform and is formed by capillaries interspersed with mesenchymal cells. Owing to the extending anterior chamber and the increasing thickening of the sclera the vessels surrounding the chamber angle become obliterated; the former process presses them laterally, toward the sclera on one side, toward the pigment epithelium on the other. Thus they form the first anlage of uveo-scleral trabecula and of the iris, and border the chamber angle. Capillary walls gradually disintegrate, while the mesenchymal cells become differentiated into various tissue fibers on which lie the released endothelial cells of the capillaries. Irido-scleral veins occur mostly in the closed tissue, though part of them are free in the chamber angle; if, through rarefaction, such a vein becomes split, the separate parts can organize and form on one side an iris nodule, and on the other the so-called anterior scleral ring. This origin is corroborated by the fact that the scleral ring is never present circularly, but always appears in isolated spots on or near the tip of the trabecula and in continuation of the irido-scleral vein which runs from Schlemm's canal to the anterior chamber and is undergoing obliteration. The first anlage of the "Skleralwulst" is in the scleral fibers which, owing to penetration of the irido-scleral vein into the sclera proper, lie on the inner side of the vein and of the sinus formed by it. Later they slowly protrude between the capillary fibers running backward from uveo-scleral trabecula. The greater development of the uveal stroma in many animals is due to the fact that in them

the irido-scleral vein or the first stromatic fibers formed in its place upon its obliteration are more strongly developed than in man. In rare human cases the same cause leads to a larger Fontana's space, which is to be regarded in man as atavistic. The stroma designated as scleral or corneo-scleral is formed without participation of the cornea, originating mostly from the uvea and, in less degree, from the sclera; therefore uveo-scleral stroma is a more fitting term. The inner canaliculi of Schlemm's canal originate from a lateral vessel of the irido-scleral vein.

8392. **STEINER, K. Über Hautbezirke mit starker Zellvermehrung bei menschlichen Embryonen.** *Arch. Dermatol. u. Syphil.* 162(3): 577-581. 4 fig. 1931.—A multiple layered, prismatic ectodermal epithelium on a cellular mesoderm poor in fibrillae is found during the 2nd and the beginning of the 3rd embryonic month in the region of the facial and branchial areas, the external genitalia, and the anlagen of the extremities. This is gradually replaced by several layers of cubical epithelium except in the region of the external genitalia and anus, where it is found in older embryos. The reduction of the areas is relative, their surface growth being slight, while the deep growth increases, giving rise to epithelial corns, cones, plates, sutures, and rolls. All these have a special histological structure. During later embryonal life and after birth special processes occur here which often explain disease phenomena due to local differences in the skin.

8393. **TAKAHASI, KEN. Pri la genezo de la papilo de nervo optika ĉe Sus scrofa domesticus. [Genesis of the papilla nervi optici in the eye of the pig embryo.]** *Folia Anat. Japonica* 9(2): 149-167. 20 fig. 1931.—The author used wax and gypsum models as well as sections. The stages studied are referable to No. 68-91 of Keibel's Normentafel. Transformation from the optic vesicle to the optic cup is completed when the chorioid fissure begins to appear in the ventral wall of the cup. At this stage the chorioid fissure comes to possess Szily's "dorsale Falte" in the space which is formed between the inner and outer layer of the cup, being wide especially at the insertion region of the optic stalk. Pari passu with the growth of chorioid fissure, the stalk groove (Stielrinne) appears on the ventral wall of the optic stalk to enclose the hyaloidal vessel. The chorioid fissure first closes in the middle region, and this process proceeds both distally and proximally. As the closure advances the stalk groove closes also successively from the distal end proximally, encircling the vessels in its center. The dorsal fold to which the stalk groove belongs now turns into a short cylindrical papilla nervi optici, surrounding the hyaloidal vessel in its center.—*Author (courtesy Wistar Bibl. Serv.).*

8394. **TREUTLER, KARL. Über das wahre Alter junger menschlicher Embryonen.** *Anat. Anz.* 71(10/13): 245-258. 1931.—The author gives a detailed description of 4 embryos 20, 27, 33, and 45 days old, the periods between cohabitation (conception) and curettage being known. A review of the theories of the period of conception is given.

8395. **WEISSENBERG, RICHARD. Grundzüge der Entwicklungsgeschichte des Menschen in vergleichender Darstellung.** 12th rev. and enlarged ed. 438p. 168 fig., 6 col. pl. Georg Thieme: Leipzig, 1931. Pr. 15 M.—This textbook of human embryology is the 12th edition of the treatise originally written by L. Michaelis. The subject is treated under the following sections:—The germ cells; fertilization; segmentation; gastrulation; formation of the mesoblast, intestine and medullary canal in *Amphioxus;* the mesoblast, chorda and medullary canal in the Amphibia; the germinal layers and first embryonic organs in fishes and birds; the germinal layers, first embryonic organs and egg membranes in mammals; the development of the chorion and placenta in the various mammalian orders. The development of the human ovum is then considered, then the development of the human placenta and decidua and then follow sections on organo-genesis, the systems being considered in the following order:—digestive, muscular, skeletal, the limbs, vascular, urogenital including the adrenal, nervous, the sense organs and the cutaneous. The penultimate section treats of the germinal layers and their relation to the various organs and tissues and the final section considers some results of experimental embryology.—*J. P. McMurrich.*

EXPERIMENTAL

8396. **BIJTEL, J. HUBERTHA. Beiträge zur Schwanzentwicklung der Amphibien.** *Anat. Anz.* 71(4/6): 87-93. 7 fig. 1930.—In development of *Amblystoma mexicanum* vital staining of the posterior portion of the medullary plate showed that the neural tube from root to tip of tail, the mesoderm of the tip, and some terminal somites developed therefrom. The chorda was never stained. A rectangular area excised from the medullary plate in *A. mexicanum* and *Triton taen[iatus]* was implanted at 180° or another neurula implanted in the abdominal ectoderm; in most cases a tail developed directed cranially or laterally; in the autogenous implant a 2nd tail appeared behind it, depending in size on the area between the caudal incision and the blastopore.

8397. **BOROVANSKÝ, LADISLAV. Srůsty druhého a třetího obratle krčního u člověka. (Přispěvek k mechanice Krční páteře.) [Synostosis between the 2nd and 3rd cervical vertebrae in man.]** *Rozpravy České Akad. Věd a Umění Tř. II.* 37(paper 25): 1-6. 1 pl. 1928.—The synostosis between the C_2 and C_3 (without any pathological processes) is much more frequent than between the other cervical vertebrae, which is explained by the minimum flexibility of the cervical spinal column between C_2 and C_3. (The human cervical spinal column is most flexible between the C_4 and C_5, or between C_3 and C_4.) The differences in the flexibility between different cervical vertebrae are characteristic for man.—*J. Florian.*

8398. **FILATOW, D. Entwicklungsmechanische Untersuchungen an Embryonen von Acipenser güldenstädtii und Acipenser stellatus.** *Zeitschr. Wiss. Biol. Abt. D, Roux' Arch. Entwicklungsmech. Organ.* 122(3): 546-583. 21 fig. 1930.—The author has extirpated the ear vesicle of the sturgeon at an early stage, and finds that although the ear capsule does not form, a concentration of mesenchyme cells takes place which gives rise to a cartilaginous structure in the ear region. If the ear vesicle be transplanted to the limb region, limb mesenchyme is attracted to it and surrounds the vesicle as does the rudiment of the auditory capsule. However, not enough limb mesenchyme is withdrawn to prevent the normal development of the limb rudiment. The author compares his results with those obtained on Amphibia.—*From author's summary (transl. by E. K. Hall).*

8399. **HELFF, O. M. Studies on amphibian metamorphosis. VII. The influence of the columella on the formation of the lamina propria of the tympanic membrane.** *Jour. Exp. Zool.* 59(1): 179-196. 1 pl., 1 fig. 1931.—A central area of the lamina propria of the anuran tympanic membrane directly over the tip of the columella becomes considerably thickened and characterized by yellow elastic fibrous elements during metamorphosis. Operations designed to throw light on the possible developmental influence of the columella on this issue were as follows: The columella was extirpated during early stages of development and the tympanic membrane removed and examined histologically, following metamorphosis. No traces of a yellow fibrous area were found in the lamina propria of the membranes. Columellae in various stages of development were extirpated and transplanted, autoplastically, beneath the pigmented membranous covering of the back musculature. In several cases typical histological yellow fibrous areas developed in the membrane directly over the end of the transplant. Annular tympanic cartilages, in fairly well-developed stages, were extirpated, attached columellae removed, and the former then transplanted, autoplastically, with their lateral covering of lamina propria,

to the back, which upon sectioning invariably lacked the yellow fibrous region of the lamina propria. The results indicate that normal development of the yellow fibrous region of the lamina propria portion of anuran (*Rana pipiens*) tympanic membrane is brought about by association and contact of the membrane with the distal end of the rapidly growing columella.—*Author* (*courtesy Wistar Bibl. Serv.*).

8400. MAY, RAOUL M. Répercussions de la greffe de moelle sur le système nerveux chez l'embryon de l'Anoure, Discoglossus pictus, Otth. *Bull. Biol. France et Belgique* 64(3): 355-387. 4 pl., 3 fig. 1930.—A piece of embryonic spinal cord, with the surrounding tissues, was transplanted homoplastically into the hind limb region in embryos of *D. pictus*, at the tail-bud stage. When the implanted spinal cord developed independently of the hind-limb on the same side, the autochthonous spinal cord and its ganglia had a symmetrical structure. But in certain cases the implantation completely inhibited the development of the homolateral hind-leg, while in 2 cases the grafted spinal cord gave rise to a large, well formed nerve, which usurped the functions of the normal lumbo-sacral plexus and innervated the homolateral hind-leg. In these cases of absence of innervation to a hind-limb from the autochthonous spinal cord, there was a reaction on the latter and its ganglia through a sensory and motor hypoplasia. The ganglia were very much reduced, and the lateral half of the spinal cord underwent a marked reduction of its white and gray matter, on the side and along the segments from which the lumbo-sacral plexus was absent. The spinal cord reduction was shown by the absence of the motor horn and by a marked asymmetry. There was also a repetition of the reduction in the neighboring segments. These results show that the hind-limb innervation plays a part in the development of both the sensory and motor neurones of the neuraxis.—*R. M. May.*

8401. MOMIGLIANO LEVI, G. Caratteri dei tenoblasti e comportamento delle fibre collagene nelle culture di tendine di embrione di pollo. [Properties of tenoblasts and collagen fibers in the cultures of tendon of chick embryos.] *Boll. Soc. Ital. Biol. Sperim.* 5(3): 321-324. 1930.—Explants of tendon of chick embryos have a long latent period preceding the migration of tenoblasts: the form of the latter differs in the early and late explants; the constitution of the migration zone and elements shows many peculiarities. Development of collagen fibers follows at a very early stage (it may begin in the 4th day of culture). The fibrillae are developed among the tenoblasts; in the 2nd week the formation of bundles begins.—*M. Comel.*

8402. MURRAY, P. D. F., and D. SELBY. Chorio-allantoic grafts of entire and fragmented blastoderm of the chick. *Jour. Exp. Biol.* 7: 404-415. 1930.—In chorio-allantoic grafts of entire unincubated blastoderms of the chick, the central nervous tissue was always tubular and was differentiated into grey and white matter. The endoderm was present as a series of tubes, probably histologically differentiated into intra- and extra-embryonic endoderm. In similar grafts of fragments of unincubated blastoderms the inhibition of differentiation is concluded to be a consequence of the fragmentation, i.e., it is the result of the isolation of the graft from the embryo as a whole.—*J. M. Robson.*

8403. PASQUINI, P. Equipotentiality of the amphibian eye primordia. *Nature* [*London*] 127(3196): 163-164. 1931.—Gives results of experiments in the transplantation of optic vesicles in *Rana catesbiana.*

8404. ROMANOFF, ALEXIS L. Cultivation of the chick embryo in an opened egg. *Anat. Rec.* 48(1): 185-189. 2 fig. 1931.—With the view of obtaining a suitable method of direct continuous observation of the developing chick embryo, under normal and adverse experimental conditions, eggs of various stages of incubation, from newly laid to 8 days, were opened by removing portions of the shell and shell membranes. The results show that it is possible to cultivate the embryo in an egg: opened before incubation—for at least 1 week; opened at from 1 to 6 days of incubation—up to the 19th day; and, opened after 6 days of incubation—up to normal hatching.—*Author* (*courtesy Wistar Bibl. Serv.*).

8405. SCHWIND, JOSEPH L. Heteroplastic experiments on the limb and shoulder girdle of Amblystoma. *Jour. Exp. Zool.* 59(2): 265-296. 8 fig. 1931.—The experiments were performed to study the behavior of portions of the girdle rudiment after heteroplastic transplantation between *A. punctatum* and *A. tigrinum*. In some cases whole or partial limb anlagen were also transplanted. A scapula and suprascapula transplanted to the other species do not keep their specificity of form. The experiments were not conclusive with respect to the ventral zone of the girdle. The presence of tissue from the donor species in one portion of the girdle has no effect on the growth of the remaining portion of the girdle formed from host tissue. The whole girdle rudiment lies anterior to a line formed by a projection of the 4th-5th somite boundary. The presence of a heteroplastic limb affects the size of the spinal ganglia supplying it but not the number of motor neurons in the spinal cord. A *punctatum* limb on a *tigrinum* larva differentiates more rapidly and becomes functional sooner than the normal limb of the host. Many limbs containing tissue from both species were obtained. The distribution of donor and host digits in these limbs showed that the material determined for the formation of digits is localized in anteroposterior direction and that the future radial border of the limb lies more ventrally and anteriorly than the future ulnar border.—*Author* (*courtesy Wistar Bibl. Serv.*).

8406. TWITTY, VICTOR C., and JOSEPH L. SCHWIND. The growth of eyes and limbs transplanted heteroplastically between two species of Amblystoma. *Jour. Exp. Zool.* 59(1): 61-82. 2 pl. 1931.—Eyes and limbs were grafted orthotopically between embryos (tail-bud stage) of *A. punctatum* and *A. tigrinum*. The nutrition was standardized by maximal feeding of both species, so that larvae of comparable size were always available for control. The heteroplastically grafted organs had the same growth rate as their normal controls on the donor species during the major portion of larval life, although differing greatly in size from the normal organs of the host. The experiments show that in transplantations between these two species the difference in size between the transplanted organ and the normal organ of the host species is due to differences in intrinsic growth factors. The close correspondence in size of the heteroplastically transplanted organ and its control on the donor species suggests a similarity in the organic environmental factors regulating the growth of the organ in the 2 forms. A résumé of the results of other investigators on heteroplastic transplantations is given and their relation to the present findings discussed.—*Authors* (*courtesy Wistar Bibl. Serv.*).

8407. WILLIER, B. H., and MARY E. RAWLES. Developmental relations of the heart and liver in chorio-allantoic grafts of whole chick blastoderms. *Anat. Rec.* 48(2): 277-301. 4 fig. 1931.—The differentiation of heart and liver has been studied in chorio-allantoic grafts of whole pellucid areas of chick blastoderms before and after the heart rudiments formed and in all cases before the liver primordium arose. Of 40 grafts examined, a heart developed in 32 and a liver in 24 cases. Both organs are histologically normal, but lack normal form. In 8 grafts the heart rudiment developed without the liver, showing its capacity to differentiate independently of the latter. The liver, however, appears to be dependent upon the heart, since it has differentiated very rarely in its absence. Contact of heart rudiment and entoderm seems necessary for the latter to differentiate into liver since when both heart and liver differentiate they are in contact (over 50% of cases) or in close association (separated by growth mechanics) and, when liver fails, gut tubes not in contact with heart are found. In 10 grafts 2 hearts have developed from each blastoderm. Except in 1 case, a liver has developed either in contact

or in close association with each heart. The entoderm originally in contact with each heart rudiment thus has the capacity to differentiate into liver. This indicates either that the entoderm in contact with each heart rudiment has the specific potencies of liver, or that any entoderm in contact with a heart rudiment may be induced to form liver.—*Authors* (*courtesy Wistar Bibl. Serv.*).

ANOMALIES, MONSTERS AND MARKED VARIATIONS IN DEVELOPMENT

8408. **ANDREUCCI, ARNOLFO.** Sopra un gallo mostruoso. [On a rooster monster.] *Atti R. Accad. Fisiocrit. Siena* 3(2/4) : 431-449. 4 fig. 1928.—In the first article the author describes the monstrosities in a chicken he dissected as completely as possible; a supernumerary foot, not articulated with the pelvis, but attached to the coccyx by ligaments; 2 cloacal apertures; various anomalous doublings and asymmetry in the region of the pelvic girdle and posterior vertebrae; incompletely doubled duodenum and doubled pancreas; 3 caecal appendages to the small intestine; doubling of the large intestine to correspond with the cloacae; some malformations and maladjustments in the urogenital system. The central nervous system apparently had no anomalies, which seem to have been confined to the posterior portion of the body.—*E. W. Count.*

8409. **ANDREUCCI, ARNOLFO.** Sulla diagnosi e la genesi delle mostruosita riscontrate in un gallo. [Diagnosis and origin of monstrosities in a rooster.] *Atti R. Accad. Fisiocrit. Siena* 3(2/4) : 451-464. 1928.—Discussing various types of double monsters, the author classifies this case as rare in manner of attachment of the supernumerary foot; as common in duplicities of that member; as unique in duodenal-pancreatic doubling and as unique in the particulars of this ischio-sacro-melus. The author cannot trace the probable embryonic origin of the anomalies. Granting the formation of 2 embryos, however they may have come about, the posterior ends apparently touched; in consequence of an external stimulus one grew more rapidly than the other, due to their disparate teratogenetic stages.—*E. W. Count.*

A case of complete fusion of placentae in cats is reported. The determination is based on features of gross dissection and the histology of the placental tissue as shown in stained paraffin sections.—*L. M. Dickerson.*

8411. **DUBREUIL-CHAMBARDEL, LOUIS.** Les variations utéro-vaginales par cloisonnement longitudinal. *Ann. Méd et Chir.* 1(1) : 111-116. 9 fig. 1927(1928).—The author classifies the uterine malformations which result from various degrees of retention of the embryologic double uterus and vagina.

8412. **FISCHER, FRANZ.** Über die intraskleralen Ziliarnervenschleifen. (Mit einem Beitrag zur Entwicklungsgeschichte der Ziliarnerven des menschlichen Auges.) *Zeitschr. Augenheilk.* 66(1/2) : 59-78. 10 fig. 1928.—Nerve loops are found 2-3 cm. in front of the angle of the eye, perhaps most frequently on the lower surface. The summit of the loop is thickened by a separation of the fibers, but no neurofibroma exists. A branch from this loop runs anteriorly in the sclera. Blood vessels, from the posterior ciliary or episcleral arteries, are only occasionally associated with the loops, and can have no causal significance. Nor is there any embryological evidence that the nerve takes a false course and returns, thus forming the loop. It is suggested that the nerve grows too long, and that this length is compensated for by formation of a loop as the sclera develops.—*J. L. Bremer.*

Complete obliteration of the descending arch at insertion of the ductus in a boy of fourteen; bicuspid aortic valve; impending rupture of the aorta; cerebral death. II. MAUDE E. ABBOTT.** A statistical study and historical retrospect of 200 recorded cases, with autopsy, of stenosis or obliteration of the descending arch in subjects above the age of two years. *Amer. Heart Jour.* 3(4) : 381-421. 9 fig.; (5) : 574-618. 3 fig. 1928.

8415. **LATASTE, FERNAND.** Questions tératologiques. III. L'iliomélie et la pubimélie, deux monstruosités radicalement différentes, confondues sous la dénomination de pygomélie. *Bull. Soc. Zool. France* 53 : 90-96. 1928.—Pygomelia includes 2 types of monsters belonging to 2 different series,—iliomelia in the autosite series and pubimelia in the parasite series.—*C. V. Morrill.*

8416. **MOSKOFF, M.** Schistosoma reflexum при овче ембрио. [Schistosoma reflexum in sheep embryo.] [In Bulgarian.] Годишникъ на Софийския университетъ, Ветеринарно-медицински факултетъ. (*Jahresber. Univ. Sofia, Vet.-Med. Fak.*) 4 : 261-270. 2 fig. 1928.—A monstrosity of about 6.5 cm. C. R. length, described in detail, represents a partial schistosoma reflexum.—*A. Kalojanoff* (*transl. by J. W. Scott*).

8417. **PEYRON, A.** Les vestiges embryonnaires de la région sacro-coccygienne et leur rôle dans la production des kystes ou tumeurs d'origine congénitale. Deuxième démonstration. Les vestiges de l'intestin caudal. *Bull. Assoc. Franç. Étude Cancer* 17(8) : 613-632. 12 fig. 1928.—The topographic evolution of the caudal intestine in mammals and man is traced histologically in 10 cases (monkeys and pigs). No observations as yet indicate a neurenteric origin for the caudal intestine. Of the published cases of pelvic and pre-sacral cysts, those of Middeldorpf and Gallelty are the only ones the origin of which can probably be ascribed to the traces in the caudal intestine. The tumors with multiple tissues reported in the neurenteric canal seem to the author to represent unrecognized embryomata of a parasitic type.

8418. **SCHILLINGS.** Le rein en fer à cheval. [Horseshoe kidney.] 104p. 8 pl., 26 fig. Les Presses Universitaires de France, Paris, 1928. Pr. 11 Belges.

8419. **SZANIAWSKI, W.** W sprawie podwojenia serca u zarodków ptasich. [Diplocardia in bird embryos.] [French résumé.] *Kosmos* (*Lwów*) 53(4) : 798-807. 1 pl., 1 fig. 1928(1929).—The author describes 2 cases of diplocardia in bird embryos. The first is from a chick of 44½ hrs. incubation. The body was normal except for the noticeably doubled condition of the heart, the 2 parts of which lay to the right and left. Length of body —3.18 mm.; breadth of right heart—0.226 mm., length—0.211 mm.; left heart—0.226 mm. × 0.233 mm.; distance between hearts—0.181 mm. In the 2nd case (rook embryo, *Trypanocorax frugilegus* L.), the shape of the heart was highly complicated, but its double nature was beyond question. The embryo was platyneural, with 20 prs. of somites. The author believes that the first of his cases could also have survived for fairly long. These cases prove that each omphalomesenteric vein can produce the anlage of a separate heart. The author believes the artificial production of diplocardia to be quite impossible.—*Author's summary* (*transl. by E. W. Count*).

8420. **TAVARES, AMÂNDIO.** Variações do tubo digestivo e suas relações com a clínica. [Anomalies of the digestive tract.] *Arquivo Anat. e Antropol.* [*Lisboa*] 12(1) : 103-188. 16 fig. 1928.—The author observed a case of a clearly bilocular stomach in a ♀ fetus at term. He found Meckel's diverticulum in 5.1% of the cases. He studied the dolichocolon, presenting 2 cases of sigmoid dolichocolon, with other congenital anomalies of the digestive tract.—*A. Tavares* (*transl. by P. L. Risley*).

8421. **WILE, IRA S., and SAMUEL Z. ORGEL. Study of the physical and mental characteristics of Mongols.** *Internat. Clinics Ser. 38* 3 : 145-201. 5 pl. 1928.—This is a presentation of a study of 25 mongolian idiots in terms of their physical characteristics, their intellectual abilities, their educability and their social origins. The variations in the intelligence quotients are marked but

should not be employed too rigidly as the basis of judgment of educational development and industrial capacity. Approximately ⅓ of the monograph is devoted to an analysis of alleged etiological factors. The authors conclude on the basis of a large amount of carefully checked data that none of the present theories are adequate to explain mongolism. The common facies cannot be accounted for by arrest of fetal development, as premature 6 or 7 mos. infants do not have such a facial similarity and further develop later marked variations. The similarity of mental levels shows a definite inhibition of growth in intellect and interferences with association fibers and cerebral organization. The variety of congenital anatomical anomalies in development suggests influences hampering cellular development and possibly inherent in the fertilized ovum. The total pattern of mongolism suggests reversion to some earlier type but there is no evidence of direct inheritance. A bibliography of 102 items is supplied.—*I. S. Wile.*

France* 53: 145-148. 3 fig. 1928.—In a ♂ crab of medium size, the abdomen was feminized in its general form and in its ornamentation of marginal setae. In addition to the 2 pairs of copulatory stylets the abdomen bore, on the left side of the 5th somite, a supernumerary pleopod, of the abortive ♀ type, the exopodite of which was trifurcate at its distal extremity.—*C. Pérez (transl. by W. M. Tattersall).*

8423. **FLORY, WALTER S. Jr., and HIRAM M. SHOWALTER. The histology of the bursa copulatrix of the turbellarian Gyratrix hermaphroditus hermaphroditus Ehrenberg.** *Trans. Amer. Microsc. Soc.* 49 (1): 66-71. 1 pl., 1 fig. 1930.—The chitinous wall of the bursa contains large nucleated cells, extending into the lumen and containing sperm. Early stages in the development of these cells, showing thin walls and sperm within the cells, but no sperm in the lumen, are followed by the bursting of the cell wall and discharge of the cell content into the lumen. The remaining cell wall assumes the form of an empty spear-shaped structure, resembling the description of "appendages" in the bursa copulatrix as described by von Graff. The lumen of the bursa contains degenerating marginal cells surrounding a multinucleated protoplasmic mass in which discharged sperm masses are visible.—*C. H. Willey.*

8424. **HAFFNER, KONSTANTIN von. Die überzähligen Bildungen des Körperstammes von Lumbriculus variegatus Müll. und ihre kausale Analyse.** *Zeitschr. Wiss. Biol. Abt. D Wilhelm Roux' Arch. Entwicklungsmech. Organ.* 123 (3/4): 649-681. 25 fig. 1931.—A lateral nick (Kerbschnitt) in the body of a worm injuring the axillary organs leads to the formation of a 2nd (lateral) anterior end in the anterior portion of the body, and, in the posterior, to a 2nd (lateral) posterior end; in the middle region of the body both a lateral anterior end and a lateral posterior end of varying development regenerate; the lateral posterior end always lies cephalad to the lateral anterior end. The causal analysis of the lateral supernumerary formations leads to the conception that they are undoubtedly regenerations of incomplete portions of the worm (not of the entire worm). Probably polarity exerts an influence on the type of supernumerary formation, in the anterior region of the body suppressing the formation of a lateral posterior end, and in the posterior region suppressing the formation of an anterior end. Polarity thus would be at least a partial antagonist of the potentialities in the worm parts incompletely isolated by the cut. Supernumerary formations on the trunk of animals of other groups are compared with those of *Lumbriculus* and apparently can be traced to similar causes.

8425. **MORETTI, GIULIO. Le cellule vescicolose dell'Helix pomatia L. e il tessuto connettivo. [Vesicular cells of Helix pomatia and the connective tissue.]** [French, English and German summaries.] *Arch. Zool. Ital.* 14 (2/4): 157-168. 1 col. pl. 1930.—The reticular connective tissue forms thin layers around the muscle fibers of *Helix* and consists of annular fibrils, sometimes forming a network. This structure is related to the structure of vesiculated cells and to the system of reticular fibrils which forms it support. Observations on the reticular fibrils and on their relations with the peripheral protoplasm of the vesicular cells are given, establishing the affinity between the vesiculated cells and fat cells.—*Author's summary.*

8426. **PENNERS, A. Entwicklungsgeschichtliche Untersuchungen an marinen Oligochäten. II. Furchung, Keimstreif und Keimbahn von Pachydrilus (Lumbricillus) lineatus Müll.** *Zeitschr. Wiss. Zool.* 137 (1): 55-119. 40 fig. 1930.—The egg of *P. lineatus,* without protoplasmic polar cap, displays a spiral type of cleavage resembling that of *Tubifex* with polar cap. Enormous somatoblasts form, teloectoblasts develop posteriorly mesoblastic elements and neuroblasts, the last named being in contact with the germ tract of the dorsal side. The mesoblastic bands unite ventrally, the divisions of the nervous system come in contact, and when 14 segments are present hatching occurs. Germ cells arise from primitive mesoblastic elements, and migrating ventrally become imbedded in the mesoblast of segments 9-11.—*Author's summary (transl. by H. Heath).*

8427. **PÉREZ, CHARLES, et ÉLIANE BASSE. Sur un monstre double de Sacculine.** *Bull. Soc. Zool. France* 53: 139-145. 5 fig. 1928.—In this *Sacculina,* observed on *Carcinus moenas,* the stalk was single, but the visceral mass was almost completely cleft, perpendicularly to the plane of symmetry of the crab, by a deep groove which divided it into 2 approximately equal halves. It was a double monster analogous to what one can imagine to happen by the proximal fusion of 2 *Sacculina* inserted at the same point.—*C. Pérez (transl. by W. M. Tattersall).*

8428. **SONNEBORN, TRACY M. Genetic studies on Stenostomum incaudatum (nov. spec.). 1. The nature and origin of differences among individuals formed during vegetative reproduction.** *Jour. Exp. Zool.* 57 (1): 57-108. 14 fig. 1930.—In studies on *S.* **incaudatum*** (p. 60), source unknown but probably eastern U. S. A., it was found that lead acetate had different effects on the anterior and posterior products of division. The present paper deals with the grounds for this difference. Series of only anterior products of division went through a continuous process of development, finally decreasing in rate of division, degenerating in structure, and dying. Such a series, therefore, has the characteristics of a single individual producing offspring from its posterior end. These posterior products of division have the characteristics of young, newly-formed individuals. A series of only posterior products of division ordinarily does not show continuity of development, decrease in rate of division, degeneration in structure, or death. Such a series is "potentially immortal." Among individuals (i.e., series of only anteriors) of a clone, there were 11 types differing in structure, development and length of life. Ten of these types—including, however, only 3% of the individuals produced—are derived only from parents undergoing structural degeneration. Within each type there is variation in the number, position, form and nature of the structures characteristic of advanced age, and in the sequence of the stages of degeneration. Differences in the structural endowment of the 11 types

of individuals are determined not merely by the age, but also by the structural condition of the parent. Some of the structures arising with age are at times transferred from parent to offspring. Differences in later development depend partly on the extent to which this occurs. Differences in length of life depend chiefly on differences in original structural endowment and on differences in the course these structures follow during development. Knowledge of these differences among individuals of a clone is important in understanding the effects of environmental conditions.—*T. M. Sonneborn.*

8429. **STAUDINGER, FRITZ. Heteromorphosen an Stigmen und anderen Gebilden bei Carausius (Dixippus) morosus Brunner. (Versuche und Naturfunde.)** *Zeitschr. Wiss. Biol. Abt. D, Roux' Arch. Entwicklungsmech. Organ.* 122(2): 316-378. 36 fig. 1930.—Experiments on the regeneration of parts of the spiracular closing apparatus of *C. morosus* were undertaken to determine something of the mechanics of developmental processes of partially symmetrical structures. The experiments were suggested by the facts that: (1) when an eye is removed a structure resembling an abdominal spiracle is regenerated in its place, (2) no regeneration results upon removal of an entire closing apparatus, (3) enantiomorphism exists between the 1st and 2nd thoracic spiracular apparatus of the same side. Each spiracle has 2 dissimilar closing plates, the 2nd spiracle differing from the 1st in having the 2 plates in the reversed position. Three sets of regeneration experiments were performed on the 1st spiracle. When either the entire structure or only the anterior plate was removed no regeneration took place. With the removal of the posterior plate there might be (a) a reduction of the spiracle and adjacent parts of the pronotum with a possible closure of the stigmal orifice, or (b) modification of adjacent parts, or (c) heteromorphotic regeneration of the posterior plate whereby a plate is formed having the characters of the anterior plate but in mirror image, or 2 such plates are regenerated, in which case the spiracular cleft is surrounded by 3 similar plates. It is suggested that this type of development may be due either to a reversal in regeneration (proximal regeneration) or else to 2 regenerative potencies whereby either the one or the other may function. The occurrence of homoeosis and other abnormalities in other parts of the species under consideration has been observed, such as branched tarsi, reversed structures interpolated between 2 normal parts and antennae exhibiting interpolated leg structures which illustrate a similar type of development. In other experiments in which an eye was removed, a structure closely resembling an abdominal spiracle was developed. Eyes likewise were regenerated regardless of whether the optic ganglion was removed or left undisturbed.—*O. A. Johannsen (from author's summary).*

8430. **TEISSIER, GEORGES. Étude expérimentale du développement de quelques hydraires.** *Ann. Sci. Nat. Zool.* 14(1): 5-60. 23 fig. 1931.—Studies in the normal embryonic development* of *Amphisbetia (Sertularia) operculata**, which is analogous to that of many craspedote medusae, were facilitated by the presence of a yellow pigment accumulated in abundance at one of the poles. An axis with 2 poles can be recognized in the oocyte and followed through all stages of development. The yellow pole is that where the polar globules are emitted, where segmentation begins, and later gastrulation. It corresponds to the posterior extremity of the planula and the oral pole of the hydrarian and ought to be considered as the vegetative pole of the egg. The endoderm of the planula is derived from the vegetative half of the egg. The first planes are meridians and the third, equatorial, separates the ectodermal and endodermal blastomeres. At the fourth division the embryo acquires a bilateral symmetry and a transverse elongation which is later gradually effaced. The blastula, at first spherical, elongates on the morphological axis. Gastrulation is accomplished by unipolar immigration, and the planula thus formed fixes itself after a few days of pelagic life. Experimental studies show that any fragment of the egg (sufficiently large) from the blastomere of stages 2, 4, 8 or 16, or a fragment of the morula or blastula will give a complete planula. Sectioning stage 8 or the blastula equatorially results in 2 complete planulas, one formed from endoderm and one from ectoderm. By experimental grafting and staining it was proved that in the processes of regulation which can transform endoderm into ectoderm or vice versa, the polarity of the fragments is conserved. In *Hydractinia echinata** and *Dynamena pumila** the pole of segmentation corresponds to the oral region as in *Amphisbetia;* but they have the endodermal and ectodermal material of the egg disposed concentrically. Fragments of the planula of *D. pumila*, if large enough, can give rise to normal colonies, but if too small only a single normal individual will be produced. The vegetative pole of the oocyte and egg is the most sensitive to chemicals; but in the blastula stage the maximum sensitivity is at the animal pole.

8431. **YUNG-TAI, TCHANG. Recherches sur l'histogenèse et l'histophysiologie de l'épithélium de l'intestin moyen chez un lépidoptère. (Galleria mellonella L.)** *Bull. Biol. France et Belgique Suppl.* 12. 1-144. 6 pl., 19 fig. 1929.—The writer first studied the habits and development of *G. mellonella* at 30°-32° C. The period of development of each stage was determined and a curve for growth in length of the larva was drawn. Particular attention was paid to the morphological characters of the larva which made it possible to recognize the approach of the molts and so to study histological phenomena during ecdysis. More than 2000 larvae of various ages were studied histologically, as well as about 1000 embryos and as many pupae. In general the larvae were fixed at intervals of 2 or 3 hrs. from one molt to the next. The histological technic is described and particular stress is laid on the value of the staining method in which magenta, picric acid, and light green were used. The epithelium of the mid-intestine of the larva is composed throughout its life of 2 categories of functional cells (cylindrical and goblet) and of small basal cells. The same cells were found in the embryonic mesenteron. During each larval molt a new epithelium is formed from the basal cells. At the beginning of their differentiation 2 categories of basal cells exist which develop directly into cylindrical cells or into goblet cells. Both types of cells degenerate from time to time. The formation and regeneration of the striated border of the cylindrical cells are described. A membrane on the surface of the striated border is formed at the same time as the striated border itself. When it separates from the border, it becomes a layer of the peritrophic membrane. The normal food of *G. mellonella* contains or yields substances that are blackened by osmic acid when absorbed. Since bodies were found only in the mid-intestine and only in the cylindrical cells there, it was concluded that absorption takes place only in the cylindrical cells of the mid-intestine, which degenerate at the end of each phase of absorption. The goblet cells appear to have a secretory function only. The cylindrical cells also seem to secrete at certain periods as indicated by the presence and behavior in the cells of granules which stained with acid fuchsin. The secreting cylindrical cells degenerate in the course of the evacuation of their products of secretion. The writer believes that a cylindrical cell during its life functions in either absorption or secretion and can not assume both functions, and that generations of secreting cells alternate with generations of absorbing cells. Both secreting and absorbing cylindrical cells in the course of degeneration produce 3 types of formations at the expense of their cell substance; i.e., nipples, spherical corpuscles, and shortened cells. The shortened cells are those that have lost their apical portion. Sometimes they acquire a new striated border. The nipples and corpuscles are similar to the secretory vesicles described by other writers. The writer believes, however, that these bodies are simply part of the degenerating cell and have nothing to do with secretion. In studying

the changes in the mid-intestine during metamorphosis, the writer has described step by step the diminution of the volume of the mid-intestine, which is effected by the folding of the epithelium followed by the detachment of the folds formed. The epithelium is renewed following the detachment of the larval epithelium and the renewals of the epithelium continue during metamorphosis. Similar renewals occur in the epithelium of the adult. The goblet cells are absent after the renewal of the larval epithelium, all the cells then being cylindrical. The secretion and degeneration of these cells, as well as the evolution of the basal cells during the whole metamorphosis, are described. In considering the origin of the basal cells the writer finds that they are isolated in the embryonic mesenteron and are grouped in nidi in very young larvae. In each nidus there is generally only one cell capable of dividing, which is situated at the center of the nidus. This is called the initial cell. However, the number of nidi, and hence the number of initial cells, increases considerably during the larval stage. The author believes that the initial cells may divide at certain times to form 2 initial cells which start new nidi. The parallel increase in the number of basal cells and of functional cells shows that the activity of the basal cells reaches its maximum during the larval stage. The continuous partial renovation of the epithelium is interpreted as a physiological renovation, whereas the periodic complete renovation at the approach of each molt is considered hereditary. Finally, certain elements in the cytoplasm of the cylindrical cells appear to be endogenous cells. Many of the foregoing points were also studied in the larva of another species of bee moth, *Achroia grisella* F. An extensive bibliography is included.—*F. L. Campbell.*

8432. **BALOZET, L. Myxosporidie d'un poisson marocain.** *Bull. Soc. Sci. Nat. Maroc* 9(7/8): 203-207. 1 fig. 1929.—Description of a *Chloromyxum** from the muscles of *Temnodon saltator* in Morocco. It is compared with *C. clupeidae** and *C. quadratum**, and seems to be identical with them both, which are considered one species.

8433. **BANCROFT, L. Flagellates in certain Queensland plants. Preliminary notes.** *Proc. Roy. Soc. Queensland* 39: 22. 1927(1928).—A flagellate in *Sarcostemma australe* and *Hoya australis*, and other species in *Secomone elliptica* and in *Ficus scabra*. *Oncopeltus quadriguttatus* sucks the milky juices of *Sarcostemma* and *Hoya* and harbors flagellates in its intestines. The flagellate is a *Phytomonas*.

8434. **BERRY, E. WILLARD. The Foraminifera of the Restin shale of northwest Peru.** *Eclogae Geol. Helvetiae* 21(1): 130-135. 6 fig. 1928.—The author lists 26 Foraminifera as found in the Restin shale (Middle Eocene), including: *Ammodiscus* **restinensis*** (p. 131), *Bolivina* **restinensis*** (p. 131), *Cristellaria* **multiseptae*** (p. 132), *C.* **peruviana*** (p. 132), *Anomalina grossergosa* v. **peruviana*** (p. 134), and *A.* **restinensis*** (p. 134).—*W. Berry.*

8435. **BERRY, E. WILLARD. The smaller Foraminifera of the Middle Lobitos shales of northwestern Peru.** *Eclogae Geol. Helvetiae* 21(2:) 390-405. 27 fig. 1928.—Lists 75 different Foraminifera from the Saman shale (Eocene) of Peru and describes the following: *Rhabdammina* **samanica*** (p. 392), *Ammodiscus* **peruviana*** (p. 392), *Cyclammina* **samanica*** (p. 393), *Trochammina* **incai*** (p. 393), *T.* **peruviana*** (p. 394), *T.* **boggsi*** (p. 396), *T.* **samanica*** (p. 396), *Textularia* **brakei*** (p. 396), *Gaudryina* **samanica*** (p. 397), *Bolivina* **samanica*** (p. 397), *Lagena* **samanica*** (p. 398), *Nodosaria* **hopkinsi*** (p. 398), *N.* **samanica*** (p. 398), *N.* **spinosa*** (p. 399), *Cristellaria* **samanica*** (p. 399), *Discorbis* **peruviana*** (p. 400), *D.* **samanica*** (p. 400), *Truncatulina lobatula* v. **peruviana*** (p. 400), *T. refulgens* v. **samanica*** (p. 400), *T.* **samanica*** (p. 402), *Anomalina* **perversa*** (p. 402), *A.* **samanica*** (p. 402), *Rotalia* **beccaroides*** (p. 402), *Nonionina* **olssoni*** (p. 403), *N.* **samanica*** (p. 403), *Nummulites* **speciosa*** (p. 404).—*W. Berry.*

8436. **BERRY, E. WILLARD. Asterodiscocyclina, a new subgenus of Orthophragmina.** *Eclogae Geol. Helvetiae* 21(2): 405-407. 1 pl. 1928.—The new subg. is transitional between *Discocyclina* and *Asterodiscus;* type *O.* (*A.*) **stewarti*** (p. 406), from the Eocene, Peru.—*W. Berry.*

8437. **BERRY, WILLARD. Note on the Nodosaria affinis d'Orbigny in the Eocene of Maryland.** *Eclogae Geol. Helvetiae* 22(2): 166. 1929.—*Nodosaria affinis* v. **baggi***, from the Nanjemoy.—*W. Berry.*

8438. **BERRY, WILLARD. The larger Foraminifera of the Atascadero limestone of northwest Peru, South America.** *Eclogae Geol. Helvetiae* 23(2): 489-496. 2 pl. 1 fig. 1930.—The following are reported from the Saman shale (Eocene): *Lepidocyclina* **atascadero*** (p. 491), *L.* **columna*** (p. 492), *L.* **brightoni*** (p. 493), *L.* **carmani*** (p. 494), *L.* **nuttali*** (p. 494), *Operculina* **atascaderensis*** (p. 495), *O.* **peruviana*** (p. 496).—*W. Berry.*

8440. **BROWN, VIRGINIUS E. The neuromotor apparatus of Paramecium.** *Arch. Zool. Exp. et Gén.* 70(6): 469-481. 1 pl. 1930.—The neuromotor apparatus consists of longitudinal ciliary fibrils, transverse commissural fibrils, and internal neurofibrils; all connected in a definite manner to the basal granules of the cilia. The pellicle is definitely sculptured with hexagons and parallelograms. Dimples occur in the centers of these hexagons. The edges of the dimples form hexagons, rhombohedrons, and squares in the contracted condition. The basal granules of the cilia are connected by the longitudinal ciliary fibrils, which curve around on the ventral region so that they meet on the preoral and postoral sutures, and transversely by the commissural fibrils. The internal neurofibrils run from the basal granules into the endoplasm, are perpendicular to the peripheral fibrils and unite with each other and curve toward the region of the mouth. The neuromotor apparatus is composed of fibrils which have both motor and sensory functions.—*V. E. Brown.*

8441. **CHAPMAN, F., and W. J. PARR. Notes on new and aberrant types of Foraminifera.** *Proc. Roy. Soc.*

Victoria 43(2): 236-240. 1 pl., 1 fig. 1931.—**HERONALLENIA** (p. 236) (Rotaliidae), near *Discorbis*, type *H.* **wilsoni*** (*Discorbina w.* Heron-Allen) (p. 240), recent, also includes *H.* **lingulata*** (*D. l.* B. & H.) (p. 240), Oligocene, and *Discorbis kempii* Heron-Allen, recent, is also referred to the genus. **HOFKERINA** (p. 237) (Victoriellidae), type *H.* **semiornata** (*Pulvinulina s.* Howchin) (p. 238), Oligocene. An anomalous specimen of *Homotrema rubrum** is described.

8442. **CUSHMAN, JOSEPH A., and YOSHIAKI OZAWA.** A monograph of the foraminiferal family Polymorphinidae recent and fossil. *Proc. U. S. Nation. Mus.* 77(6): 1-185. 40 pl. 2 fig. 1930.—This study of the family Polymorphinidae is based upon extensive studies of many thousands of specimens. Wherever possible the types were studied in European and other museums, and where not available topotype material was studied. Most studies of this group are based upon side and apertural views, but the basal view gives the key to the development of the test. Both clockwise and contraclockwise arrangements of the chambers occur. In some species these seem to be fixed while in others both clockwise and contraclockwise arrangements occur in the same species. Fistulose outgrowths occur in many species, usually at the apertural end, but in some specimens extend over the whole surface, becoming very complex. Special names have been given such forms by earlier authors, but it seems that they should be grouped with non-fistulose forms of the same basal characters. Fistulose forms are often difficult to identify as the outgrowths may obscure the structure and arrangement of the chambers. The systematic classification of the family is based upon a study of the development and of the geologic sequence of forms. In the earliest Jurassic species the chambers form a loose spiral from which both biserial and tetraloculine forms develop and become extinct in the early Cretaceous. Quinqueloculine forms develop and give rise in later development to numerous groups of triloculine, biloculine, uniserial, and sigmoid forms. A number of new genera and many new species are described, the types of which are indicated: **EOGUTTULINA** (p. 16), type *E.* **anglica*** (p. 16), Cretaceous, England; *E.* **liassica** (*Polymorphina l.* Strickland) (p. 17), Liassic formation, England; *E.* **polygona** (*Polymorphina p.* Terquem) (p. 17), Lr. Lias, France; **QUADRULINA** (p. 18), type *Q.* **rhabdogonioides*** (*Polymorphina r.* Chapman) (p. 18); *Q.* **frondicularioides** (*Polymorphina f.* Chapman) (p. 19), "pebble bed, Littleton"; *Q.* **lagenalis** (*Polymorphina l.* Terquem) (p. 19), Lr. Lias; **PALEOPOLYMORPHINA** (p. 112), type *P.* **pleurostomelloides*** (*Polymorphina p.* Franke) (p. 112); *P.* **gatulina** (*Polymorphina g.* Berthelin) (p. 112), Lr. Carboniferous, France; *Guttulina* **bartschi*** (p. 23), "Albatross" D5178, off Romblon, Philippines; *G. irregularis* v. **nipponensis*** (p. 27), Up. Pliocene, Japan; *G.* **frankei*** (p. 28), Middle Oligocene, Germany; *G.* **hantkeni*** (p. 33), Eocene, Hungary; *G. regina* v. **crassicostata*** (p. 35), Lr. Pliocene, Victoria, Australia; *G. adhaerens* v. **cuspidata*** (p. 37), Cretaceous, England; *G.* **jarvisi*** (p. 39), Tertiary, lower marl, Cipero section, Trinidad; *G.* **lehneri*** (p. 39), Tertiary, lower marl, Trinidad, Brit. W. Indies; *G.* **yamazakii*** (p. 40), "Albatross" D4807, off Cape Tsiuka, Japan; *G.* **kishinouyi*** (p. 40), Up. Pliocene, Japan; *G.* **baileyi*** (p. 41), "Albatross" D2416, off southeastern coast of the U. S. A.; *G. lactea* v. **earlandi*** (p. 45), recent in Mediterranean, Pliocene (Crag) of Sutton and Selsey, England; *G.* **schafferi*** (p. 45), Miocene, Tortonian, *Amphistegina* marl of Grunes Kreuz, Austria; *G.* **woodsi*** (p. 45), Cretaceous, lower Gault, England; *G.* **paalzowi*** (p. 46), Up. Cretaceous of Maastricht, Holland; *Guttulina* **dawsoni*** (p. 47), Quebec; *G.* (*Sigmoidina*) **silvestrii*** (p. 51), Miocene (Janjukian), Victoria, Australia; *Pyrulina* **albatrossi*** (p. 58), "Albatross" D2160, off Cuba; *Globulina gibba* v. **verrucosa*** (p. 67), Lutetian, France; *G. g.* var. **fissicostata*** (p. 67), Up. Oligocene, Germany; *G. lacrima* v. **ericia*** (p. 78), chalk marl of Saxon Cement Works, Cambridge, England; *G.* **flexa*** (p. 81), Up. Oligocene, Germany; *G.* **triserialis*** n. sp. (p. 88), Miocene, Helvetian, France; *Pseudopolymorphina* **suboblonga*** (p. 91), Up. Pliocene, Japan; *P. suboblonga* v. **jugosa*** (p. 91), Sea of Japan; *P.* **atlantica*** (p. 94), "Albatross" dredgings off eastern coast of the U. S. A.; *P.* **phaleropei*** (p. 95), Atlantic coast of Massachusetts; *P. rutila* v. **parri*** (p. 100), Miocene, Janjukian, Victoria, Australia; *P.* **paucicostata*** (p. 101), Eocene, Texas; *P.* **ovalis*** n. name (p. 103), *Amphistegina* marl of Grunes Kreuz, Vienna; *P.* **curta*** (p. 105), 32 fathoms, Casco Bay, Maine; *P.* **dollfussi*** (p. 106), Miocene, Burdigalian, France; *P. d.* var. **tenuistriata*** (p. 106) and *P.* **jonesi*** (p. 107), Miocene, France; *Polymorphina* **fornasinii*** (p. 114), recent of Tripoli; *P.* **longistriata*** (p. 115), Thanet beds of Pegwell Bay, England; *P.* **alleni*** (p. 116), Eocene, Isle of Wight, England; *P.* **schlumberger*** (p. 121), Miocene, Aquitanian, France; *P.* **howchini*** (p. 121), Lr. Pliocene, Victoria, Australia; *Sigmomorphina* **nuttalli*** (p. 124), Eocene, Trinidad, Brit. W. Indies; *S.* **lamarcki*** (p. 131), Eocene (Lutetian), France; *S.* **pearceyi*** (p. 132), Dry Tortugas, Florida, 18 fathoms; *S.* **schencki*** (p. 133), Oligocene (Keasey shale), Oregon; *S.* **kotoi** (p. 134), Up. Pliocene, Japan; *S.* **trinitatensis*** (p. 134), Eocene, Trinidad, Brit. W. Indies; *S.* **bornemanni*** (p. 134), Middle Oligocene, Germany; *S.* **galloway*** (p. 135), "Albatross" D4807, coast of Japan; *S.* **vaughani*** (p. 137), Eocene (Cooper marl), S. Carolina; *S.* **aliceae** (p. 139), "Albatross" D4805, off Japan; *Sigmoidella* **plummerae** (p. 142), Eocene, Texas; *S.* **margaretae*** (p. 142), Up. Pliocene, Japan; *Glandulina* **reussi*** (p. 144), Oligocene, Germany.—*J. A. Cushman.*

8443. **CUSHMAN, JOSEPH A., and JAMES A. WATERS.** Foraminifera of the Cisco group of Texas (exclusive of the Fusulinidae). *Univ. Texas Bull.* 3019. p. 22-81. 3 maps, 11 pl. 1930.—Field stations are described and the best collecting grounds are mapped. This upper Pennsylvanian fauna is primitive in character; even specialized types are not complex. Many previously known forms, some new to the Cisco group, are described and figured. *Hyperamminoides* **glabra** (*Nodosinella g.* Cushman & Waters) (p. 36); *Glomospira* **reversa*** (p. 42), Gaptank formation; *G.* **diversa*** (p. 42), Harpersville formation; *Endothyra* **pauciloculata*** (p. 47), Wayland shale of Graham formation; *Trochammina* **grahamensis*** (p. 68), South Bend shale member of Graham formation; *Globivalvulina bulloides* (H. B. Brady), type specimen; *Placopsilina* **ciscoensis*** (p. 74), Graham formation. Types in Cushman coll.

8444. **[DAGAEVA, V. A.]** ДАГАЕВА, В. А. Инфузории Соляного озера Круглой бухты близ Севастополя. **[Protozoa of the Salt lake of Kruglaia Bay, near Sevastopol, Crimea.]** [German summary.] Академия Наук СССР., Труды Севастопольской Биологической Станции. (*Acad. Sci. URSS., Trav. Sta. Biol. Sebastopol*) 2: 31-46. 1930.—Most of the protozoa of the lake are Black Sea forms, fresh water and typical salt lake forms completing the fauna. Higher temp. and a lower salt content favored the abundance of protozoan forms, the salt content being the more important factor.—*S. A. Corson.*

8445. **DENNIS, EMERY WESTERVELT.** The life history of Babesia bigemina in the North American fever tick. *Science* 73(1901): 620-621. 1931.—*Margaropus annulatus* (Say) is the obligatory vector of this protozoan parasite in N. Amer., and its life history, a one-host tick, makes the life history of *B. bigemina* inseparable from the developmental cycle of the tick. Sexual phenomena and sporogony take place in the tick. Details are given. The sporozoites are inoculated into the blood stream of the bovine host in the saliva of the feeding seed-tick, and soon set up an active infection of the erythrocytes of the host.

8446. **DOBELL, CLIFFORD.** Researches on the intestinal protozoa of monkeys and man. IV. An experimental study of the histolytica-like species of Entamoeba living naturally in macaques. *Parasitology* 23 (1): 1-72. 1931.—Detailed report of studies and experiments in inoculation of *Entamoeba histolytica* into *Macacus sinicus*, *M. rhesus*, and *M. nemestrinus*, and also kittens, leads the writer to conclude that the *Entamoeba* living naturally in the three species of monkeys is identical with *E. histolytica* of man. It is possible to isolate any strain of the organism and maintain in vitro for any required period, and to obtain at will any stage in its life history in vitro at any given moment; to introduce this strain into a natural host (*Macacus*), study its behavior therein and recover in culture whenever necessary; and to eradicate it from the host permanently by chemotherapeutic methods. *E. histolytica hominis* (= *E. h. macacorum*).

8447. **DRYDEN, A. L. Jr.** Glauconite in fossil foraminiferal shells. *Science* 74 (1905): 17. 1931.—The author reports 2 more cases.

8448. **GAJEVSKAJA, N.** Über einige seltene Infusorien aus dem Baikalsee. Известия Академии Наук СССР., Отделение Физико-Математических Наук. (*Bull. Acad. Sci. URSS, Cl. Sci. Phys.-Math.*) 1929 (9): 845-854. 4 fig. 1929.—*Dactylophrya* **collinii*** (p. 845), from Gammaridae, Lake Baikal, the genus having been known previously only from the Atlantic Ocean. *Acineta truncata** and *Burscllа spumosa** are also recorded.

8449. **[GRIGOROVA, O. P.]** ГРИГОРОВА, О. П. Малярийный плазмодий обезьян. [Malarial plasmodium of monkeys.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии. (*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*) 7 (10): 698-702. 1929.—Plasmodium found in *Cercocebus aethiopicus* has following characteristics: mature gametocytes were mostly in the form of macrogametocytes, with pale, greenish-blue, net-like protoplasm; the nucleus was situated at the periphery and contained a characteristic achromatic zone. The pigment was rather coarse, greenish-brown, distributed sometimes rather evenly, sometimes concentrated more centrally. In addition to mature macro- and microgametocytes, there were also found young and transitional forms. The blood was characterized by a considerable anisocytosis. Erythrocytes measured 2.6-6.0 μ. There were also polychromatophilia, slight poikilocytosis, and hypochromia. Outward manifestations of disease were very slight. Plasmodium found in *Papio sphinx* differed from the first as follows: young forms were encountered but rarely, usually in the later stage of schizogony, occupying a considerable part of the erythrocyte. Macrogametocytes were slightly larger than a normal erythrocyte, and contained a delicate greenish-blue, reticulated structure, with an evenly distributed delicate greenish-brown pigment. Pigmentation of microgametocytes was also more delicate than in the first case. Gametes were much larger. The author does not affirm that the parasites in the 2 cases belong to different species.

8450. **[GURVICH, V. F.]** ГУРВИЧ, В. Ф. Фауна простейших кишечника лягушек окрестностей Ташкента. [The protozoan fauna of the intestine of frogs in the environs of Tashkent.] [French summary.] Бюллетень Средне-Азиатского Государственного Университета (*Bull. Univ. Asie Centrale* [*Tashkent*]) 14. 47-61. 2 pl. 1926.—All classes of protozoans are represented in this fauna. The protozoans do not seem to be affected by changes in condition of the frogs, such as captivity or hunger. *Opalina elongata* is described in detail in its various phases*. Gametogeny and copulation of *O. elongata* may occur within adult frogs as well as within tadpoles. The systematic characters hitherto employed in the classification of *Opelina* are uncertain and need to be supplemented by cytological characters.

8451. **KARTCHNER, J. A., and ELERY R. BECKER.** Observations on Eimeria citelli, a new species of coccidium from the striped ground-squirrel. *Jour. Parasitol.* 17 (2): 90-94. 1 pl. 1930.—*E. citelli** (p. 94), from *Citelli tridecimlineatus*. Notes are given on host specificity as well as on the life history of the organism including the region of infection within the host. Artificial infections were produced to determine size variation throughout an infection. All infections proved to be self-limited. —*J. A. Kartchner.*

8452. **[KHEĬSIN, E. M.]** ХЕЙСИН, Е. М. К биологии паразитических инфузорий различных беспозвоночных озера Байкала. [Biology of infusorian parasites of various invertebrates of Lake Baikal.] Доклады Академии Наук СССР., Сер. А. (*Compt. Rend. Acad. Sci. URSS., Sér. A.*) 1930 (5): 121-126. 1930.—A table lists 55 spp. of invertebrates of various orders, with the number of different spp. of Infusoria found in each at various localities, and the text discusses the meaning of these statistics. The distribution of parasites in Lake Baikal is more or less even.

8453. **KOCH, RICHARD.** Tertiärer Foraminiferenkalk von der Insel Curaçao (Niederländisch West-Indien). *Eclogae Geol. Helvetiae* 21 (1): 51-56. 1 pl., 1 map. 1928. —The author records 13 spp. of larger Foraminifera, among them *Lepidocyclina* **curasavica*** (p. 54) and 6 kinds of smaller Foraminifera from the Oligocene rocks, northwest Curaçao. The map shows the localities.—*W. Berry.*

8454. **LESTOQUARD, F.** Existence de "corps en grenade" dans le cycle évolutif de Gonderia ovis. *Compt. Rend. Soc. Biol.* 100 (14): 1177-1178. 1929.—The existence of "grenade bodies" in *G. ovis* of smaller ruminants is reported. The author concludes that the genus *Gonderia* falls into synonymy with *Theileria*. *Gonderia ovis* becomes *Theileria* **recondita** (*Theileria ovis* being preoccupied) (p. 1178). The hematozoans of small ruminants are *Piroplasma ovis* (ss.), *Babesiella ovis, Theileria recondita, T. ovis, Anaplasma ovis.*

8455. **OZAWA, Y., and A. TOBLER.** Permian Fusulinidae found in Greece. *Eclogae Geol. Helvetiae* 22 (1): 45-49. 1 pl. 1929.—Nine spp. of *Fusulina* are reported from Hydra and Katakupho Isls., including *Sumatrina* **pesuliensis*** (p. 48), Pesulia, Katakupho Isl.—*W. Berry.*

8456. **OZAWA, Y.** A new occurrence of Schwagerina princeps in Sumatra. *Eclogae Geol. Helvetiae* 22 (1): 51-52. 1929.—*S. princeps* Ehrenb. is noted from the Productus limestone (Upper Permian of Meyer) of Telok and referred to the Permian-Carboniferous of the author; the occurrence of *Neoschwagerina craticulifera* Schwager and *Fusulina japonica* Gumbel is also noted.—*W. Berry.*

8457. **PAYNE, M. ANTHONY.** Metachaos granulosa in Kansas; third recorded appearance of Gruber's rare ameba. *Bull. Univ. Kansas, Sci. Bull.* 19 (2): 275-279. 1 pl. 1930.—The species is described and its history discussed.

8458. **PLUMMER, HELEN JEANNE.** Calcareous Foraminifera in the Brownwood shale near Bridgeport, Texas. *Univ. Texas Bull.* 3019. p. 5-21. 1 pl. 1930.—A discussion of the types of Pennsylvanian tests and their alteration precedes the systematic section. **EARLANDIA** (p. 12) (Hyperamminidae), near *Hyperammina*, erected for *E.* **perparva*** (p. 13); *Nodosinella* **perelegans*** (p. 14); *Endothyra* **watersi*** (p. 15); *Endothyranella* **armstrongi*** (p. 18); *Hemigordius* **regularis*** (p. 20); *Orthovertella* **sellardsi*** (p. 21). Types in Plummer coll. Several previously known spp. are also recorded. The transfer by Galloway and Hulton of various spp. to their genus *Endothyranella* is questioned.

8459. **SHIBUYA, MASATAKE.** Notes on two ciliates, Cyrtolophosis mucicola Stokes and Gastrostyla philippinensis sp. nov., found in the soil of the Philippines. *Proc. Imp. Acad.* [*Tokyo*] 7 (3): 124-127. 3 fig. 1931.—*C. mucicola** is described. The author "thinks it reasonable to deal with *C. major* as synonymous with *mucicola.*" *Balantiophorus elongatus* is deemed referable to *Cyrtolophosis*. **PINCHATIA** (p. 126) [no diagnosis; affinities not explicitly stated], erected for *Balantiophorus chaetophorae* Penard and *B. mucicola* Penard. *Gastrostyla* **philippinensis*** (p. 126).

8460. SILVESTRI, A. Sulla Conulites cooki del Carter. *Riv. Ital. Paleont.* 33(1/2): 23-36. 2 pl., 1 fig. 1927.—*C. cooki** is found in the Lr. Eocene of the Sind in Beluchistan, and Arabia. The name *Conulites* Carter is preoccupied by two usages in Mollusca and *C. cooki* was referred to *Dictyoconoides* by Nuttall, but the writer holds that *C. cooki* is incompatible with *D. conditi* Nuttall and is not willing to assign it to that genus. He redescribes the animal and illustrates for comparison with it, *Dictyoconus codon**, *D. pulbroeauensis**, *D. aegyptiensis**, *Orbitolina lenticularis**, and *Chapmania gassinensis**.

8461. TOBLER, A. Über Pseudocyclammina und Choffatella im Schweizerischen Juragebirge. *Eclogae Geol. Helvetiae* 21(1): 212-216. 1 pl. 1928.—After a discussion of the 2 genera the author describes *Pseudocyclammina* personata* (p. 213), from the Malm. The genus *Choffatella* occurrences are summarized.—*W. Berry.*

8462. TOBLER, A. Miogypsina dans le falun de Pontpourquey près de Saucats, Bordilais. *Eclogae Geol. Helvetiae* 21(2): 385-387. 1 pl. 1928.—From the presence of *Miogypsina* the author decides the age of the shell marl is upper Burdigalian and not Helvetian.—*W. Berry.*

8463. TOBLER, AUG. Maeandropsina im Tertiär von Ostborneo. *Eclogae Geol. Helvetiae* 20(2): 321-323. 1 pl. 1927.—Describes *Maeandropsina** sp. from the Lower Miocene of east Borneo.—*W. Berry.*

8464. TOBLER, AUG. Pellatispira im Priabonien von Lenk (Berner Oberland). *Eclogae Geol. Helvetiae* 22(2): 172-175. 1929.—The author states that *P. douvillé* Boussac is not the same as *Nummulites madaraszi* von Hantken and redescribes von Hantken's type as *P. madaraszi* von Hantken sp.—*W. Berry.*

8465. TOBLER, AUG. Alveolinenfunde im Eocän der nördlicher Kalkalpen. *Eclogae Geol. Helvetiae* 22(2): 175-180. 1929.—A discussion, accompanied by a table showing occurrence of the genus but without listing spp., is given of *Alveolina*, as portrayed by 9 authors.—*W. Berry.*

8466. TURNER, JOHN P. A simple apparatus for washing protozoa. *Science* 73(1908): 99-100. 1 fig. 1931.

8467. TUZET, ODETTE. Protistologica XXV. Une grégarine parasite de Bythinia tentaculata L., Gonospora duboscqui n. sp. Appareil de Golgi, mitochondries, vacuome. *Arch. Zool. Exp. et Gén. Notes et Rev.* 71(1): 16-20. 3 fig. 1931.—*G. duboscqui** (p. 16), near Montpellier, France. Studies of cytoplasmic structure are briefly reported, featuring the globose mitochondria, Golgi apparatus, and dictyosomes.

8468. WANG, CHIA-CHI. Notes on some new and rare species of hypotrichous Infusoria. *Contrib. Biol. Lab. Sci. Soc. China. Zool. Ser.* 6(2): 9-18. 10 fig. 1930.—Descriptions of *Urostyla* paragrandis* (p. 9), *Stichotricha* acuminata* (p. 11), *Oxytricha fallax** Stein, *O. caudata** Stokes, *Euplotes* novemcarinata* (p. 16), all from Nanking district.

PORIFERA

M. W. DE LAUBENFELS, *Editor*

(See also in B. A. 6(2): Entries 3319, 5259; and in this issue 6983, 9061)

8469. ARNDT, W. Lebensdauer, Altern und Tod der Schwämme. *Sitzungsber. Ges. Naturforsch. Freunde* 1928(1/3): 23-44. 1 fig. 1928.—Calcarea: spp. live 3 mo. to 1 yr. Triaxonida: no definite ages are known, but these are thought to live the longest of all sponges. Tetraxonida: 1 sp. is known to live at least 2 mo. Cornacuspongida: some are known to live more than 50 yrs. Fresh-water sponges live from a few weeks to more than 4 yrs. Causes of death include senescence, (especially in annual spp. and those producing gemmules), chemical and physical changes in the surrounding water, bacterial infections, and consumption as food by annelid worms, insect-larvae, and especially gastropods. Human agencies are often responsible for destruction to sponges.—*M. W. de Laubenfels.*

8470. ARNDT, WALTHER. Haltung und Aufzucht von Meeresschwämmen. In: **EMIL ABDERHALDEN. Handbuch der biologischen Arbeitsmethoden. Abt. IX. Methoden der Erforschung der Leistungen des tierischen Organismus.** Teil 5, Heft 4, Lief. 326. pp. 465-598. 40 fig. Urban u. Schwarzenberg: Berlin, 1930. Pr. 9 M.—A discussion of methods of obtaining marine sponges and of keeping them in the laboratory. Types of dredging equipment and aquaria used, lighting, condition of the water as to temperature, alkalinity, and salinity, together with the food and the enemies of sponges, are considered. A brief summary of methods of open sea sponge culture is given.—*T. C. Nelson.*

8471. BURTON, M. Additions to the sponge fauna at Plymouth. *Jour. Marine Biol. Assoc. United Kingdom* 16(2): 489-507. 9 fig. 1930.—Six spp. are added to the faunal list for Plymouth, collected by M. W. de-Laubenfels, types in the Brit. Mus. *Halichondria* bowerbanki (p. 489); *Mycale similaris* (Bowerb.); *Iophon hyndmani* (Bowerb.); *Endectyon* delaubenfelsi* (p. 492); *Hymedesmia* stephensi* (p. 494); *Myxilla* topsenti (p. 497); PACHAXINELLA (Axinellidae) (p. 503), type *P.* subdola* (*Halichondria s.* Bowerb.) (p. 504). A key to the spp. of *Endectyon* is given, and a key and some redescriptions from types of the 21 spp. of *Hymedesmia* recorded from the British Isles, including *H.* dendyi* (p. 496) and *H.* bronstedi* (p. 497); *H.* armiger (*Hymeniacidon a.* Bowerb.) (p. 499). The validity of *Hymedesmia acutostellata* Hanitsch is questioned.—*M. W. de Laubenfels.*

8472. BURTON, MAURICE. Mission Saharienne Augiéras-Draper, 1927-1928. Porifera. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1(2): 157-158. 1 fig. 1929.—A brief note on *Spongilla carteri* and *Potamolepis leubnitziae.*

8473. PELTZMANN, IDA. Amblysiphonella und Bryozoen aus dem Oberkarbon der Karawanken [Jugoslavia]. *Mitteil. Naturwiss. Ver. Steiermark* 67: 123-127. 9 fig. 1930.—*A. alpina** (p. 123); *Geinitzella crassa**; and *Rhombocladia delicata.*

8474. RENOUF, L. P. W. Some new records [of sponges] for the Clyde sea area. *Glasgow Nat.* 9: 65-66. 1919/1930(1931).

8475. WILSON, H. V., and J. T. PENNEY. A new variety of the hexactinellid sponge Rhabdocalyptus dawsoni (Lambe) and the species of Rhabdocalyptus. *Proc. U. S. Nation. Mus.* 76(8): 1-9. 2 pl. 1930.—*R. d.* var. alascensis* (p. 1), 100 fathoms, Cape Spencer, Alaska.—*M. W. de Laubenfels.*

COELENTERATA AND CTENOPHORA

P. L. KRAMP, *Editor*

(See also in this issue Entries 8182, 8185, 8192, 8202, 8205, 8206, 8215, 8430, 9059, 9061)

8476. [LIBROVICH, L. S.] ЛИБРОВИЧ, Л. С. К находке граптолитовой фации верхнего силура в Южном Урале. **(Discovery of a graptolitic facies of the Upper Silurian in South Ural.)** [English summary.] Известия Главного Геолого-Разведочного Управления. (*Bull. Geol. & Prospecting Service, USSR. [Leningrad]*) 49(1): 103-118. Map. 1930.—The author records 5 spp. of *Monograptus* suggesting the Ludlow (Silurian) stage, and *Archaeosigillaria* cf. *primaeva* of Upper Devonian age from strata in the Kuragan River. Their bearing on the problematical age of the igneous and metamorphic rocks of the region is of importance.

8477. **WALTHER, CONRAD.** Untersuchungen über die Mitteldevon-Oberdevongrenze (Schluss). *Zeitschr. Deutschen Geol. Ges. A. Abhandl.* 80(2): 97-152. 34 fig 1928.—A theory of septate coral cups is given, and descendants of the Lythophyllacea in the late Middle Devonian are described. **ENTELEIOPHYLLUM** (near *Dialythophyllum*) (p. 103), erected for *E.* **hagenense** (p. 106), and *E.* **sundwigense*** (p. 106); *Neostringophyllum** Wedekind, discussion; *N.* **praecursor*** (p. 111); *N.* **inchoatum*** (p. 112); *N.* **planum*** (p. 113); *N.* **simplex*** (p. 113); *N.* **concavum*** (p. 114); *N.* **complicatum*** (p. 115); *N.* **coniforme** (p. 116); *N.* **regressum** (p. 116); **TEMNOPHYLLUM** (Pexiphyllidae) (p. 120), with *T.* **latum*** (p. 123); *T.* **astrictum** (p. 124); *T.* **nodosum*** (p. 125); *T.* **inflatum*** (p. 126); *T.* **obliguum** (p. 126); *T.* **resupinatum** (p. 126); *T.* **tenue** (p. 127); *T.* **major** (p. 127); *T.* **clavatum*** (p. 128); *T.* **ornatum** (p. 128); **PEXIPHYLLUM** (Pexiphyllidae) (p. 128), with *P.* **primum** (p. 130); *P.* **rectum*** (p. 130); *P.* **altum*** (p. 132); *P.* **arcuatum*** (p. 133); *P.* **ultimum** (p. 133). From early Upper Devonian there are described **APOLYTHOPHYLLUM** (p. 135), with 6 spp.,—*A.* **gracile*** (p. 139); *A.* **cylindricum*** (p. 140); *A.* **brevissimum** (p. 142); *A.* **rectum** (p. 143); *A.* **tenuissimum*** (p. 143); *A.* **normale*** (p. 144). All from Germany. Fourteen zones are defined by these corals. The above are apparently n. spp., although not so labelled.—*L. F. Kindle.*

PLATYHELMINTHES AND MESOZOA

H. W. STUNKARD, *Editor*

(See also in this issue Entries 7512, 7514, 7516, 7519, 7521, 7523, 7524, 7529, 7541, 7542, 7543, 7550, 7551, 7555, 7562, 7564, 8423, 8428, 8490, 8511, 8575, 9061)

8478. **BRIGHENTI, DINO.** Materiali zoologici raccolti dalla spedizione Albertini nello Svalbard Nord-Orientale. IV. Descrizione di una nuova specie di Tetrabotride parassita delle Foche. *Boll. Zool. Unione Zool. Italiana* 2(4): 137-141. 1 fig. 1931.—*Tetrabothrius* **albertinii*** (p. 137) from duodenum of *Phoca maculata.*

8479. **BYCHOWSKY, BORIS.** Neue Dactylogyrus-Arten aus dem Aralsee. *Zool. Anz.* 95(9/10): 233-240. 8 fig. 1931.—*Dactylogyrus* **wunderi*** (p. 234), on gills of *Abramis brama,* Aral Sea, and on *A. brama* and *Blicca bjorkna,* near Leningrad; *D.* **propinquus*** (p. 236), on gills of *Abramis sapa; D.* **culwieci*** (p. 237), on gills of *Barbus brachycephalus* and *B. bulatmai; D.* **simplicimalleata*** (p. 239), on gills of *Pelecus cultratus.*

8480. **EJSMONT, L.** Über zwei Schistosomatidengattungen der Vögel. *Bull. Internat. Acad. Polonaise Sci. et Lett. Cl. Sci. Math. et Nat. Sér. B.: Sci. Nat. (II)* [*Zool.*] 1929(8/10): 389-403. 1 fig. 1929.—The genus *Dendritobilharzia* is redefined, based upon specimens of *D. pulverulenta,* the type species. **PSEUDOBILHARZIELLA** (p. 395), is described, type *P.* **kowalewskii** (p. 400), represented only by ♂♂ from an avian host. These specimens had been considered by some investigators to be immature ♂♂ of *Bilharzia polonica,* which had become greatly elongated after death. Ejsmont, however, states that these are mature and that the organs are well developed.—*W. A. Hoffman.*

8481. **HJORTLAND, ARTHUR LORIMER.** On the structure and life history of an adult Triaenophorus robustus. *Jour. Parasitol.* 15(1): 38-44. 1 pl. 1928.—Larval forms of this cestode from the musculature of *Leucicthys tullibee,* and larval and adult forms from the intestine of *Esox lucius,* both from Minnesota lakes, are redescribed. This cestode undergoes its earlier development in some plankton form, possibly a sp. of *Cyclops;* when the latter is eaten by *L. tullibee* the larvae migrate into the musculature and develop further. With the eating of *L. tullibee* by *E. lucius,* the larvae are released and complete their development in the intestine of the latter host.—*O. L. Williams.*

8482. **JOYEUX, C., and JEAN G. BAER.** On a collection of cestodes from Nigeria. *Jour. Helminthol.* 8(1): 59-64. 4 fig. 1930.—Records *Inermicapsifer arvicanthidis* from *Hybomys univittatus, Lemniscomys striatus, Mastomys erythroleucas,* and *Taterona kempi; Inermicapsifer guineensis* from *Arvicanthis rufinus, Cricetomys buchanani,* and *C. emini; Oochoristica herpestis* from *Atelerix spiculus* and *A. spinifex; Raillietina baeri* from *Funisciurus anerythrus, Malacomys edwardsi, Mastomys erythroleucas, M.* sp., and *Praomys tullbergi; R. trapezoides* from *Arvicanthis mordax, Lemniscomys striatus,* and *Taterona kempi; Hymenolepis scalaris* from *Crocidura* sp.; *H.* **pearsei*** (p. 60), from *Hybomys univittatus; H.* **uncinispinosa*** (p. 61), from *Hybomys univittatus, Mastomys erythroleucas; Catenotaenia lobata* from *Mastomys erythroleucas* and *Taterona kempi; Taenia taeniaeformis* from *Rattus rattus* (liver); *Duthiersia fimbriata* from *Varanus* sp. A table gives the differences between *Hymenolepis uncispinosa* and *H. globirostris.*—*F. J. Meggitt.*

8483. **LUCKER, JOHN T.** A new genus and new species of trematode worms of the family Plagiorchiidae. *Proc. U. S. Nation. Mus.* 79(19): 1-8. 1 pl. 1931.—**HAPLOMETRANA** (p. 1), type *H.* **intestinalis*** (p. 2), Washington, in U. S. N. Mus., from intestine of *Rana pretiosa.* A diagnosis is given of the subfam. Plagiorchiinae and the systematic position of the new sp. is discussed.

8484. **MARCU, O.** Über eine Missbildung von Cotugnia poliacantha Fuhrm. [Malformation in C. polyacantha.] *Bul. Fac. Stiinte, Cernauti* 1(1): 194-198. 1927.

8485. **NASONOV, N.** Vertreter der Fam. Graffillidae (Turbellaria) des Baikalsees. Известия Академии Наук СССР., Отделение Физико-Математических Наук. (*Bull. Acad. Sci. URSS., Cl. Sci. Phys.-Math.*) 1930(8): 727-738. 7 fig. 1930.—**BAICALELLIA** (p. 727), based on *B.* **baicali*** (p. 729), with vars. **fasciata** (p. 730) and **bicornis** (p. 731); *B.* **albicauda*** (p. 731); *B.* **nigrofasciata*** (p. 732); *B.* **pellucida*** (p. 733); *B.* **maculata*** (p. 734) with vars. **coerulea** (p. 734) and **nigra** (p. 735); *B.* **ocellata** (p. 735); *B.* **posieti** (p. 736); *B.* **brevitubus** (*Provortex b.* Luther) (p. 737).

8486. **PERKINS, MICHAEL.** Cambridgeshire planarians (Tricladida) with a preliminary list of the Rhabdocoelida. *Nat. Hist. Wicken Fen* Pt. 4. 346-355. 1 fig. 1928.

8487. **ROBESON, J. M. Jr.** The macro- and microscopic anatomy of Dalyellia triangulata, nov. sp. *Zeitschr. Wiss. Biol. Abt. A, Zeitschr. Morph. u. Ökol. Tiere* 20(2/3): 599-612. 16 fig. 1931.—A short history of the genus *Dalyellia* is given. Methods for preparing these flatworms for study are set forth. *D.* **triangulata*** is new.—*J. M. Robeson.*

8488. **SINITSIN, D.** Studien über die Phylogenie der Trematoden. IV. The life histories of Plagioporus siliculus and P. virens, with special reference to the origin of Digenea. *Zeitschr. Wiss. Zool.* 138(3): 409-456. 15 fig. 1931.—[Trematoda: Digenea: Allocreadiidae] *Plagioporus* **siliculus** (p. 409), Oregon, pseudoparthenita and cercaria* in the liver of *Gonabiasis plicifera silicula;* adolescaria* in the abdominal muscles of *Potamobius* sp., marita* in *Salmo clarki;* the adolescaria in the crayfish are able to produce eggs; *P.* **virens** (p. 415), Oregon, pseudoparthenita and cercaria* in liver of *Fluminicola virens;* adolescaria in the liver of *F. virens* and in the cavity of trematode parthenitae of unknown sp. living in it, marita* in intestine of *Cottus* sp.(?). The development of the ovary, and the life cycle of the group Digenea is discussed and illustrated, with the miracidium and redia of *Fasciola magna.* In hypothetical diagrams the generalized anatomy of the Digenea miracidium (cupar-

thenita), redia (pseudoparthenita), and marita, are illustrated. The Digenea are not related to the Turbellaria or Cestoda, but show relations to the Rotatoria in cell constancy, hexactinian symmetry, certain features of the nervous system, excretory system, the intestine as represented in the rediae, and the ovary. The author places Dinophilea, Digenea, Rotatoria, and Crustacea within one phylogenetic group.

NEMATHELMINTHES AND NEMATOMORPHA

M. C. HALL, *Editor*

B. G. CHITWOOD, *Associate Editor*

(See also in this issue Entries 6179, 6190, 6364, 6365, 6366, 7510, 7511, 7512, 7514, 7522, 7533, 7550, 7552, 7555, 7562, 7564, 9061)

8489. **AUBERTOT, MAURICE. Nematodes d'Alsace. Observations sur le Rhabditis pellio Schneider.** *Bull. Assoc. Philomathique d'Alsace et de Lorraine* 7(3): 178-190. 6 fig. 1927 (1928).—Free-living nematodes from Strasbourg, resembling *R. pellio*, were studied for 5 years in a culture medium of potato soup. The author believes that he has a new strain or race of *R. pellio*. The worms are shorter than known forms and the post embryonic development is more rapid (about 48 hours at 18-20° C.). The 3rd-stage larvae encyst when without food; during dry periods, however, they stand perpendicular to the surface of the medium and cling to flies (*Drosophila*), thus being carried from the unfavorable environment.—*M. Aubertot (transl. by G. F. Otto)*.

8490. **BAYLIS, H. A. Some new parasitic nematodes and cestodes from Java.** *Parasitology* 21(3): 256-265. 9 fig. 1929.—Nematoda: *Spinicauda* **longispiculata*** (p. 256), in the intestine of *Gekko gecko;* **AUCHENACANTHA** (p. 261) (Oxyuridae, Oxyurinae), based on *A.* **galeopteri*** (p. 257), in the intestine of *Galeopterus variegatus,* with also *A.* **spinosa*** ♀ (p. 260), *A.* **corollata** (*Oxyuris corollatus* Schneider) (p. 262), and *A.* **coronata** (*Oxyuris c.* v. Linstow) (p. 262). Cestoda: Oochoristica **parva** (p. 262), in *Lygosoma chalcides; Dilepis* **jacobsoni***, in the intestine of *Eucichla cyanura; D.* **javanica*** (p. 264), in *Eucichla cyanura.*

8491. **CHANDLER, ASA C. New genera and species of nematode worms.** *Proc. U. S. Nation. Mus.* 78(23): 1-11. 2 pl. 1931.—**BOURGELATIOIDES** (p. 1) (Oesophagostominae), erected for *B.* **traguli*** (p. 2), Calcutta, from small intestine of *Tragulus javanicus; Cystidicola* **harwoodi*** (p. 3), New York, from stomach of *Salvelinus fontinalis;* **LITOMOSOIDES** (Filariidae, Filariinae) (p. 4), type *L.* **sigmodontis*** (p. 5), Texas, from thoracic cavity of *Sigmondon hispidus; L.* **circularis** (*Filaria c.* v. Linst.) (p. 6); *Filariopsis* **arator*** (p. 6), Illinois, from lungs of *Cebus* sp.; **FILARIOPSIDAE** (p. 8) (Filarioidea), type *Filariopsis* van Thiel. Types in U. S. Nation. Mus.

8492. **COBB, N. A. Marine free-living nemas. In: Australasian Antarctic Expedition 1911-1914, leader Sir Douglas Mawson.** *Sci. Repts. Ser. C—Zool. & Bot.* 6(7): 5-28. 14 fig. Alfred Kent, Government Printer: Sydney, 1930, Pr. 5 s.—Descriptions and figures of 15 spp. of marine free-living nemas from mud and about the holdfasts of brown algae in Commonwealth Bay, Adelie Land: *Anticoma subsimilis* Cobb, *Tripyloides* **vivipara*** (p. 9), *Monhystera* **naviculivora*** (p. 11), *M.* **neglecta** (p. 12), *M. septentrionalis* Cobb, *Cobbia* **mawsoni*** (p. 14), *Metalinhomoeus* **meridionalis*** (p. 15), *Parasabatieria* **antarctica*** (p. 16), *Chromadora* **dubia*** (p. 17), *Euchromadora meridiana* Cobb, *Spilophora* **aberrans*** (p. 19), *Monoposthia* **apiculata***, **HYPTIOLAIMUS** (p. 22) (near *Oncholaimus,* with *H.* **cephalatus*** (p. 22), *Axonolaimus* **antarcticus*** (p. 23), *A. polaris** Cobb. In the intestine of *Monhystera naviculivora* were many diatoms, chiefly *Navicula cancellata, N. aspera* v. *antarctica, N. gracilia* v. *antarctica,* and perhaps one or two *Achnanthes antarctica.—G. Thorne.*

8493. **CRAM, ELOISE B. A new nematode from the rat, and its life history.** *Proc. U. S. Nation. Mus.* 68(15): 1-7. 2 pl. 1926.—*Protospirura* **columbiana*** (p. 1), from stomach, esophagus and small intestine of rats, in Washington, D. C., type in U. S. Nation. Mus. Key to spp. of *Protospirura* is given. Development of encysted larvae was carried out in cockroaches, apparently reaching the infective stage in 41 days. Mature nematodes were developed in rats which were fed infected cockroaches, and required 115 days to reach the size of nematodes in natural infections. The fact that infection is confined to the vicinity of the Zoological Park suggests that one of the rodents there is the normal host.

8494. **CRAM, ELOISE B. Life histories of some roundworms parasitic in poultry.** *World's Poultry Congress* 4(Sect. C.): 529-534; résumé sect., 67-68. 2 pl. 1930.—The writer records experimental data on the life histories of 5 spirurids of poultry and game birds in the United States. For *Tetrameres americana**, the ♀ of which burrows into the glands of the proventriculus and becomes globular in shape and blood-red in color, grasshoppers (*Melanoplus femurrubrum* and *M. differentialis*) are the intermediate hosts. In the muscles of the grasshoppers, the larvae develop in 42 days, or sooner, to a stage infective for chickens. In the chicken, the immature parasites, after 14 to 16 days, burrow into the glands of the stomach, the ♀♀ preceding the ♂♂. Within 45 days eggs of the parasite are passed. For the gizzard worms, *Cheilospirura hamulosa,* of domestic poultry, and *C. spinosa**, of gallinaceous game birds, *Melanoplus femurrubrum* and *M. differentialis* serve as intermediate hosts, the larvae of *C. hamulosa* being infective for chickens after 22-67 days in the grasshopper. In the chicken, between the 20th and 25th days, the larvae burrow into the muscular wall. They become adults at the end of 76 days. *C. spinosa* does not burrow into the muscular wall, but lies between it and the horny lining. For *Dispharynx spiralis* of poultry and gallinaceous game birds, the sow-bug, *Porcellio scaber,* is intermediate host, the larvae developing to infectivity within 28 days in the sow-bug, and to maturity in 27 days in the bird host. A sp. of *Gongylonema* occurs as larvae in dung beetles, *Copris minutus* and *Phanaeus vindex,* and in chicken or rabbit develop to adults, identified tentatively as *G. ingluvicola,* which occurs in nature in chickens and turkeys.—*From author's résumé.*

8495. **GOODEY, T. On the presence of fats in the intestinal wall of nematodes.** *Jour. Helminthol.* 8(2): 85-88. 1930.—Spp. in which the fats have been demonstrated are: *Rhabditis aspera, R. pseudoxycerca, R. monhystera, Cephalobus rigidus, C. persegnis, Dorylaimus longicaudatus, Plectus granulosus, Diplogaster longicauda, Myolaimus heterurus, Aphelenchus parietinus, A. fragariae, Tylenchus robustus, T. dubius, T. pratensis, T. intermedius, T. musicola, T. hordei,* and *T. dipsaci.*

8499. MAN, J. G. de. Beschreibung einer neuen Art der Gattung Craspedonema Richters, Craspedonema zeelandicum n. sp. *Arch. Hydrobiol.* 17(3): 507-514. 12 fig. 1926.—In September, 1925, one ♂ and 2 ♀♀ of this n. sp. were found in cow dung in a meadow not far from Ierseke (Zeeland, Holland).—*P. W. Bowman.*

8500. PAI, SITSAN. Die Phasen des Lebenscyclus der Anguillula aceti Ehrbg. und ihre experimentell-morphologische Beinflussung. *Zeitschr. Wiss. Zool.* 131(2): 293-344. 80 fig. 1928.—(1) The embryo is wormlike 2 days after fertilization and the egg hatches after 3 more days of intrauterine growth. The life period from fertilized egg to physiological death is 49 days for ♀♀ and 48 for ♂♂. The progressive phase averages, respectively, 20 and 30 days; the regressive, 2-3 days. (2) The anteroposterior axis is recognizable shortly before fertilization. The 1st plane of division divides the egg into an anterior (S_1) and a posterior (P_1) blastomere. Dorsoventral axis and median plane are determined in the 3-cell stage. Germ layers are established as follows: fertilized egg (P_0), primary ectoderm (S_1), entomesoderm (S_2) secondary and tertiary ectoderm (S_3, S_4), tertiary entoderm (S_5). Independent primary germ cell (P_2). (3) The S_1 group of cells yields about $\frac{4}{5}$ of the subcuticula with the 2 lateral rows of cells, the nerve and sensory cells, the excretory organ, vulva and spicula; S_2 group, midgut, pharynx, esophagus, body musculature and connective tissue; S_3 group, about $\frac{1}{5}$ of the subcuticula with the 2 lateral rows of cells of the tail; S_4 group, hindgut; S_5 group, somatic parts of the ovary, oviduct, uterus, and receptaculum seminis, and of spermary, vas deferens, vesicula seminalis, and ductus ejaculatorius. (4) "Cell constant" is applicable only to the fullgrown animal and includes constancy in number, form, size, and location. Animals whose development ends in cell constants are called "eutelic animals." They do not have the power of regeneration in any phase and have that of cytoplasmic repair only in the progressive phase. The cell constant of the midgut is reached 2 days after fertilization. The cell constants of other organs, excepting the subcuticula with the 2 rows of lateral cells, and the somatic parts of the reproductive organs, are reached soon after birth. The various organs and their cell constants are listed. (5) Full maturity is attained and growth ceases when the cell constant is reached. Ova 5 days overmature disintegrate; spermatozoa do not. Senility is indicated 2-3 days before death by decreased muscle tone, cessation of reproduction, decided decrease in digestive power, and histological degeneration of organs. (6) The pharynx of *A. aceti* is a digestive organ. The midgut is a simple tube with 18 large epithelial cells but no gland cells; it has become an absorption organ. The central nervous system has 8 ganglia; the peripheral, 5 nerve cords. (7) When the S_1 and P_1 blastomeres are separated, S_1 disintegrates but P_1 develops into an embryo. Amputation of the tail end, including a nucleus or nuclei, kills the animal. If the amputation does not include removal of the nucleus in growing animals, healing or cytoplasmic repair follows. Senile animals die immediately after the amputation. Four tables of amputation experiments are given. There is a summary and a bibliography.—*H. F. Nachtrieb.*

8501. PETERS, B. G. Some nematodes met with in a biological investigation of sewage. *Jour. Helminthol.* 8(3): 165-184. 22 fig. 1930.—The following nematodes from the zoogloeal film surrounding the sewage percolator stones at Brent (London) are described: *Diplogaster striatus**, *Diploscapter coronata**, *Dorylaimus* **saprophilus*** (p. 176); *Rhabditis* sp.*—*F. J. Meggitt.*

8502. RAUTHER, MAX. Zweiter Cladus der Vermes Amera, Nemathelminthes. Allgemeine Einleitung zur Naturgeschichte der Nemathelminthes. In: **Willy Kükenthal's Handbuch der Zoologie** 2(4): 1-7. 1 pl. 1929.—Search for a definition of the term Nemathelminthes shows that the Vermes here assembled as Nemathelminthes, namely, Rotatoria, Gastrotricha, Echinoderida, Nematoda, Nematomorpha, and Acanthocephala, all possess a similar type of organization, although they are not closely enough related to constitute a systematic or phylogenetic type sensu strictu. The history of the concept Nemathelminthes is elaborated.—*M. Rauther (transl. by E. C. Faust).*

8503. REITER, MATTH. Zur Systematik und Oekologie der zweigeschlechtlichen Rhabditiden. *Arb. Zool. Inst. Univ. Innsbruck* 3: (93)-(184). 105 fig. 1928.—The ecological occurrence and method of culture are described. Mold growths, gases, and especially bacteria are of more importance in culture than dryness, too great dampness, or poor food. A detailed account of anatomy, a list of primary and secondary specific criteria, and a key to spp. precede the detailed descriptions of 14 spp., including *Rhabditis* **longispina*** (p. 70); *R. pellio* v. **conica*** (p. 77), in garden soil, Germany; *R. maupasi* v. **gongyloides*** (p. 81), in decayed *Brassica gongylodes**, Germany.

8504. SCHMIDT, OTTO. Sind Rüben- und Hafer-Nematoden identisch? *Wissensch. Arch. Landw. Abt. A. Pflanzenbau* 3(3): 420-464. 9 fig. 1930.—By means of statistics of variation in the length of larvae of *Heterodera schactii*, the presence of 2 separate forms in central Germany was established. The beet nematode was identified as one, and the oat nematode as the other. The statistics show: average larval length, beet-form 0.47,

oat-form 0.575; standard of deviation, beet-form 0.035, oat-form 0.032; coefficient or variation, beet-form 7.5, oat-form 5.6. The two forms differ physiologically in feeding on different plants, in their reaction to stimuli, and in the rhythm of their life cycle. On the basis of morphological and biological differences the larger oat nematode is designated as *Heterodera schactii* spp. **maior** (p. 461); the smaller beet nematode, *H. s.* ssp. **minor** (p. 461). Larvae were measured inside the roots. *H. s. maior* lives on oats, barley, wheat, and rye; *H. s. minor* on Chenapodiaceae and crucifers. In reaction and hatching experiments both races were tested on root secretion of their host plants. In *H. s. minor*, beets and rape produced a very pronounced hatching, whereas oats and wheat had no effect. The reaction experiments with *H. s. maior* were mostly negative, as there was no hatching, and the physiological reaction is not yet clarified. In the past, the infestation of a field could be determined only by picking the cysts from the sediment obtained by washing the soil through sieves, the cysts being examined for their living contents. Now it is possible to determine and predict, on the basis of the length of the larvae, the races present and which plants will be menaced in a rotation. Studies of the geographic distribution of both forms have been made in central Germany and southern Sweden. Only a few cases were examined from the rest of central Europe. The result agreed with the criteria of races. A conclusion as to the crossing of the 2 races cannot yet be made. Apparently crossing does not take place. The fact that the beet nematode is not propagated through rotation on oats is economically important.—*O. Schmidt (transl. by B. G. Chitwood).*

8505. SCHNEIDER, GUIDO. Zweiter Beitrag zur Kenntnis der Brackwasser-Nematoden Finlands. II. *Acta. Soc. Fauna & Flora Fennica* 56 (7): 1-47. 6 fig. 1924-1927.—Redescriptions of 22 spp.; *Chromadora* **pachydema*** (p. 21); *Spilophorella* **dentata*** (p. 28); **DESMOLAIMINAE** n. subfam. (p. 35); *Desmolaimus* **fennicus** (p. 36); unnamed n. gen. and n. sp.* (p. 40); *Hypodontolaimus* **balticus** (*Chromadora baltica* Gui. Schn.) (p. 26). A table showing relative abundance of the 26 spp. is given.—*A. C. Walton.*

8506. SCHNEIDER, GUIDO. Dritter Beitrag zur Kenntnis der Brackwasser-Nematoden Finlands. *Acta Soc. Fauna & Flora Fennica* 56(10): 1-24. 6 fig. 1924-1927[1927].—Records of the occurrence of 37 free-living spp. of nematodes are presented. *Paracanthonchus caecus* v. **balgensis** (p. 8) and *Aphelenchus* **teres** (p. 20) are new; *Viscosia viscosa, Dorylaimus stagnalis, Chromadora macrolaima, Aphanolaimus pulcher*, Monhystera microphthalma, M. stenosoma,* and *Sphaerolaimus balticus**, are redescribed.—*A. C. Walton.*

8507. SCHUURMANS STEKHOVEN, J. H., Jr. Over Nemas en hun larven, IV. [Nemas and their larvae.] [English summary.] *Tijdschr. Plantenziekten* 35(3): 73-95. 3 pl. 1929.—The plant nemas *Aphelenchus fragariae* from begonia, *A. olesistus* v. *longicollis* from *Scilla campanulata* and *Colchicum,* and *A. ritzema-bosi* are described, particularly the head and the esophagus and its bulbus. The author concludes that *A. fragariae* R.B. is not identical with *A. ormerodis* R.B.—*D. L. Elze.*

8508. VOGEL, H., und E. G. VOGELSANG. Neue Filarien aus dem Orang-Utan und der Ratte. *Zentralbl. Bakt. Abt. I. (Orig.)* 117(7/8): 480-485. 4 fig. 1930.—Dissection of an old *Pongo pygmaeus* from Borneo disclosed in the right ventricle 2 ♂ filarids, similar to *Dirofilaria magalhaesi* and *D. immitis,* but specifically different; the authors call it *D.* **pongoi** ♂* (p. 480). The measurements of the new sp. are compared with those of the 2 other spp. of the genus parasitizing the heart of man and dog. A ♀ of another sp. was found in the thoracic muscles of another orang-utan, probably not a *Dirofilaria,* since it is oviparous. In a domestic rat from Java were found 1 adult ♂ and two adult ♀ filarids and numerous microfilariae, the adults apparently originating in the peritoneal cavity and the microfilariae infesting the blood. The authors call the species *D. bonnei** (p. 483).

8509. WEHR, EVERETT E. A new species of nematode worm from the sage grouse. *Proc. U. S. Nation. Mus.* 79(3): 1-3. 3 fig. 1931.—*Habronema* **urophasiana*** (p. 1), Montana, from gizzard of a sage grouse, *Centrocercus urophasianus.* Key to North American spp. of *Habronema* in birds.

8510. WEHR, EVERETT E. Description of a new genus and species of nematode worm occurring in the northwestern belted kingfisher, with a key to the genera of the subfamily Acuariinae. *Proc. U. S. Nation. Mus.* 79(5): 1-4. 5 fig. 1931.—**AVICULARIELLA** (p. 1) (Acuariinae), type *A.* **alcyona*** (p. 1), from gizzard of *Ceryle alcyon caurina,* Montana, in U. S. Nation. Mus.

8511. ANONYMOUS. *Jour. Parasitol.* 14(3): 197-203. 1928.—One hundred fourth meeting held April 16, 1927. E. W. PRICE: (1) Coyote, *Canis latrans texensis,* from Texas, a new host for *Oncicola canis* and *Oslerus osleri.* (2) The occurrence of *Ostertagia bullosa* in a prong horn antelope, *Antilocapra americana.* (3) The civet, *Bassariscus astutus flavus,* a new host for *Uncinaria lotoris.* J. A. SCOTT: In the dog, the normal host of *Ancylostoma caninum,* the number of larvae given per os which will develop varies from 80% in puppies to 1% in older dogs. In the rat, an abnormal host, none will develop; and in the cat from 0.1% to 0.5%. In every case a certain percentage remain as infective larvae. Such larvae recovered after 2 weeks were fed to susceptible puppies and in every case the usual percentage developed normally. Similar larvae when fed to kittens failed to develop, but when recovered 2 weeks later, and fed to puppies, the usual percentage grew. BENJAMIN SCHWARTZ: *Sarcocystis* sp. in the heart of an elk, *Cervus canadensis,* from Helena, Montana. G. F. WHITE: A method for obtaining infective nematode larvae from cultures. One hundred sixth meeting held Oct. 15, 1927. N. A. COBB: Discussed a new sp. of *Ascarophis* from the gills of the sting-ray (to be described in the Jour. Wash. Acad. Sci.). M. C. HALL: Apparently a residuum of anaplasmosis in cattle is being left behind the advancing wave of tick eradication. Diseased cattle from areas free from cattle fever ticks, are apparently not infested by ticks of any sort. This indicates that anaplasmosis is being transmitted by some vector other than fever ticks. One hundred seventh meeting held Nov. 19, 1927. E. W. PRICE: A list of helminth parasites occurring in Texas based on specimens from animals examined post mortem at the A. and M. College of Texas from 1919 to 1920, and on a small collection from local hospitals. The host animals are: horse and mule, cattle, sheep and goat, swine, dog, cat, man, rabbit, chicken, ostrich. BENJ. P. YOUNG: Infestation and prepatent period of *Eimeria avium* in chicks. CHARLES REES: Effects of rice starch on the growth and pathogenicity of *Endamoeba histolytica.* HERBERT RATCLIFFE: Relation of intestinal pH to the intensity of trichomonad infections in albino rats. EUGENE SCHUMAKER: *Iodamoeba* in a chimpanzee. ELIZABETH P. SANDERS: Infestation with 3 different spp. of Protozoa (*Trypanosoma equiperdum, Endamoeba histolytica,* and naturally acquired coccidiosis) cause characteristic changes in the blood of kittens. ROBERT W. HEGNER: The ingestion of red-blood corpuscles by trichomonads. E. B. CRAM: Fiber cells of the banana, passed by a child, and pulp vesicles of citrus fruit, passed by a dog, in the rôle of pseudoparasites. BENJAMIN SCHWARTZ: (1) A nodular disease of the intestine of the carabao in the Philippine Is. due to an undescribed sp. of the nematode genus *Cooperia.* (2) *Cysticercus cellulosae,* 4 days after feeding to dogs, showed some development, 10 days after feeding, considerable growth, but none were found 60 days after feeding. M. C. HALL: At Moultrie, Georgia, from 5,000 swine slaughtered, 19,000 lbs. of livers, kidneys, kidney fat, sweetbread, and casings were condemned on inspection for parasitism.—*J. R. Christie.*

8513. **HEATH, HAROLD. A connecting link between the Annelida and the Echiuroidea (Gephyrea armata).** *Jour. Morph. and Physiol.* 49(1): 223-250. 3 pl., 2 fig. 1930.—During the course of a hydrobiological survey of Monterey Bay, California, a series of pelagic organisms was taken at a depth of approximately 350 m., which appears to be a link connecting the Echiuroidea on the one hand and the polychaetes on the other. The range in body length is from 5 mm. to 27 mm.; and in an extended condition the anterior end of the body, with its palps and cirri, bears a close resemblance to a nereid. The supra-oesophageal ganglia and the ventral nerve cord, with eleven pairs of ganglia, are also strikingly annelidan in character. On the other hand, the spacious coelom, communicating with the exterior by a pair of anterior nephridia, allies it with the gephyreans. The same is likewise true of the gonad, which arises from the coelomic epithelium surrounding the genital vessel. The various systems are described in detail, and their resemblances to those of other annelids are indicated. The n. fam. **POEOBIIDAE** (p. 244), is erected for the genus **POEOBIUS** (p. 243), type *P.* **meseres** (p. 243). The family is considered, provisionally, to be a member of the class Echiuroidea (*Gephyrea armata*).—*Author (courtesy Wistar Bibl. Serv.).*

8526. **PICKFORD, G. E. The Oligochaeta of Wicken Fen. Part I. Lumbricidae.** *Nat. Hist. Wicken Fen Pt.* 3. 215-232. 1 pl. 1926.

8527. **SUN, KUO HUA, and KARL C. PRATT. Do earthworms grow by adding segments?** *Amer. Naturalist*

65(696) : 31-48. 1931.—Studies of species characteristics, number of segments and length of worm, of *Helodrilus foetidus* at different developmental stages (emergence from cocoon, worms without clitella and mature worms) present no evidence of continued segmentation after leaving the cocoon. There is no statistically significant difference between the means for number of segments of the intermediate and mature stages but there is a 34.5% increase in length. There is a statistically significant difference (D. of M. ÷ P. E. of D. of M. = 7.06) between the means for number of segments in newly hatched and intermediate stages but the increase in segments is only 5.51% whereas the increase in body length is 78.62%. Since the range in segment number of newly hatched worms is greater than in later stages (some newly hatched worms have more segments than any mature worms) it seems probable that segment number at maturity is determined by selective environmental factors rather than continued segmentation.—*K. C. Pratt.*

8528. **TREADWELL, AARON L.** A new West Indian polychaetous annelid. *American Mus. Novitates* 461. 2p. 3 fig. 1931.—*Cirratulus* pallidus*, Montego Bay, Jamaica.—*A. L. Treadwell.*

8529. **WAGIN, W. L.** Chaetogaster limnaei K. Baer als Cercarienvertilger. *Zool. Anz.* 95(1/2) : 55-59. 2 fig. 1931.—This annelid is a parasite in the mantel cavity of pulmonates *Limnaea* spp., *Planorbis corneus, P. carinatus, P. planorbis, Stagnicola palustris,* and *S. peregriformis* in Neva Bay, each mollusk harboring 70-100 worms, sometimes up to 900, and yet the worms seem to occasion the host no harm. *Chactogaster* feed on various Infusoria, small Rotatoria, young Cladocera, diatoms, and cercaria* in great numbers. Among the cercaria eaten were *Cercaria stylosa,* a parasite of *Limnaea stagnalis,* which later seems to develop into a parasite of fishes and finally water fowls; and *Cercaria cristata,* which develops into *Sanguinicola,* a blood parasite of *Carassius carassius* and other Cyprinidae.

ECHINODERMATA

8530. **ADKINS, W. S.** Texas Comanchean echinoids of the genus Macraster. *Univ. Texas Bull.* No. 3001. p. 101-120. 2 pl. 1930.—A key is given to the 4 Texan genera of Brissidae, and to the 9 Texan spp. of *Macraster.* The systematic account includes synonymy and descriptive and taxonomic notes. *Macraster* kentensis* (p. 106), Duck Creek and Fort Worth formations; *M.* pseudoelegans* (p. 108), Denton (type) and Fort Worth formations; *M. elegans* (Shumard), emended description; *M.* obesus* (p. 116), Weno formation. Types in coll. of Texas Bureau of Econ. Geol. *Epiaster* washitae (*Macraster w.* Lambert) (p. 119).

8531. **DEHÉE, RENÉ.** La faune marine du terrain houiller inférieur de Merville. *Ann. Soc. Géol. du Nord* 52: 286-295. 1 pl. 1927.—From the lower coal beds at Merville (northern France, Carboniferous) are found fragments of 2 spp. of fish, 2 of gastropods, 3 of pelecypods, and an echinoid, *Archaeocidaris* meurevillensis* (p. 290).—*W. Berry.*

8532. **FISHER, W. K.** Report on the South American sea stars collected by Waldo L. Schmitt. *Proc. U. S. Nation. Mus.* 78(16) : 1-10. 8 pl., 2 fig. 1931.—This list (18 spp.) is based on material collected during 1926-1927, and includes synonymies, taxonomic notes, and a considerable discussion of the genus *Anasterias.* The range included is Peru, Chile, Juan Fernandez Is., Patagonia and Falkland Is.

8533. **GRIEG, JAMES A.** Echinodermata from the Palmer Archipelago, South Shetlands, South Georgia and the Bouvet Island, with description of a new species of the Molluscan genus Montacuta. *Norske Vidensk.-Akad. Oslo, Sci. Results of the Norwegian Antarctic Exp. 1927-1928 and 1928-1929.* No. 2. pp. 1-16. 1929.—The material contained 17 spp. (1 sea lily, 6 sea stars, 5 brittle stars, 2 sea urchins, and 3 sea cucumbers). Also the lamellibranch mollusk, *Montacuta* christenseni (p. 14), Shetland Is., in *Abatus cavernosus.*

8534. **JAKOVLEV, N.** Le genre Petschoracrinus et le passage des crinoïdes dicycliques aux crinoïdes monocycliques. Доклады Академии Наук. СССР. Сер. А. (*Compt. Rend. Acad. Sci. URSS. Sér. A.*) 1930(2) : 27-29. 2 fig. 1930.—A broken base of the chalice of this genus reveals a column so small as to border on atrophy. The transition from a dicyclic to a monocyclic base in this genus, by fusion of the basal and infrabasal plates, invalidates the use of such characters for separating subclasses.

8535. **JAKOVLEV, N.** Sur les pores primaires de Cystoblastus. Доклады Академии Наук СССР. Сер. А. (*Compt. Rend. Acad. Sci. URSS. Sér. A.*) 1930(2) : 30-32. 1 fig. 1930.—A madrepore and a gonopore in the upper extremity of the interradial area of *Cystoblastus kokeni* are described and figured.

8536. **JAKOVLEV, N.** Sur la découverte du proboscis anal chez le genre Cupressocrinus. Доклады Академии Наук СССР., Сер. А. (*Compt. Rend. Acad. Sci. URSS., Sér. A.*) 1930(17) : 463-464. 2 fig. 1930.—The discovery of this feature* accords with the assignment by Bather and Jaekel of *Cupressocrinus* to the Cyathocrinidae.

8537. **JEANNET, ALPH.** Sur des Echinides tertiares du Venezuela et de la Trinité conservés au Musée d'Histoire Naturelle de Bâle. *Eclogae Geol. Helvetiae* 21(2) : 372-375. 1928.—Lists 9 spp. from the Priabonien (upper Eocene), 5 as new; 1 from the Oligocene; 3 from lower Miocene, 2 new; 2 from uncertain lower or middle Miocene; 20 from middle Miocene, 10 new. No descriptions. Notes first occurrence of *Heteroclypeus* in America.—*W. Berry.*

8538. **LERICHE, MAURICE.** Une Ophiure du "Panisélien" de la mer du Nord (Ophiurites eocaenus nov. sp.). *Bull. Soc. Belge Géol. Paléont. et Hydr.* 40(2) : 109-119. Map, 1 pl., 3 fig. 1931.—*O.* eocaenus* (p. 114), Eocene, type in Univ. Bruxelles.

8539. **LIVINGSTONE, ARTHUR A.** On some new and little-known Australian asteroids. *Rec. Australian Mus.* 18(1) : 15-23. 5 pl. 1930.—Goniasteridae: PSEUDOGONIODISCASTER (p. 15), near *Goniodiscaster* in Goniasterinae, type *P.* wardi* (p. 16), Queensland; *Nardoa* mamillifera* (p. 20), Torres Str. Types in Australian Mus. Illustrations and descriptions of specimens are given for *Tamaria tuberifera*, T. fusca*, and *Ferdina ocellata*.

8540. **LIVINGSTONE, ARTHUR A.** On the restriction of the genus Ferdina Gray (Asteroidea). *Australian Zool.* 6(4) : 305-309. 4 pl. 1931.—The author divides *Ferdina* into 2 genera and gives an emended diagnosis of the restricted genus, which includes *F. flavescens** and *F.* heffernanii* (p. 306), Santa Cruz Isl., Melanesia, type in Australian Mus. NEOFERDINA (p. 307), type *N.* cumingii* (*Ferdina c.* Gray) (p. 307), including also *N.* glyptodisca (Fisher), n. comb. (p. 307), *N.* kuhlii (*Scytaster k.* M. & Tr.) (p. 307), *N.* offreti (Koehler), n. comb. (p. 307), *N.* ocellata (H. L. Clark), n. comb. (p. 307), and *N.* cancellata (*Ferdina c.* Grube) (p. 307). The last is probably a synonym of *N. cumingii,* of which an emended description is given.

8541. **MATSUMOTO, HIKOSHICHIRÔ.** Outline of a classification of Echinodermata. *Sci. Rept. Tôhoku Imp. Univ. Sendai, Japan Geol. Ser.* 13(2) : 27-33. 1929.

—The following systematic changes are proposed: Subphylum **CRINOZOA** (p. 27), including class Cystidea, with 3 orders, Aporita Zittel, Diploporita Zittel, and Rhombifera Zittel; and class Blastoidea, with the new order **PROTOBLASTIDA** (p. 27) (Protoblastoidea Bather, in part) erected to include the Blastocrinidae, the order Codonoblastida Bather ("vel Mesoblastida mihi") (p. 28), and the order **EUBLASTIDA** (p. 28) (Eublastoidea Bather, in part), which includes the new series **PENTREMITIDA** (p. 28) (for the Pentremitidae of authors). Under the class Crinoidea and order Monocyclica Inadunata Bather, there is erected the new suborder **CALCEOCRINACEA** (p. 28) (Calceocrinidae auctt.); Crinoidea, order Monocyclica Camerata, contains 2 new suborders—**BATOCRINACEA** (p. 29) (for Batocrinoidea Bather, ext.), and **MELOCRINACEA** (p. 29) (for Melocrinoidea Bather, plus Platycrinidae). The subclass Dicyclica Bather is divided into 2 "grades," one new: **DICYCLICA TESSELLATA** (p. 29) (Tessellata auctt., pars). Under the order Articulata Müller, the suborder **ENCRINACEA** (p. 30) (Encrinidae auctt.), is new; under the 3rd suborder Pentacrinacea Newmayr, the family **ISOCRINIDAE** (p. 31) (Pentacrinidae auctt., pars) is new; and also the 4th suborder **HOLOPODA** (Holopodidae auctt., Holopida Clark).

8542. **MORTENSEN, TH. A monograph of the Echinoidea. I. Cidaroidea.** One volume text of 551pp. and 173 fig. one volume of 88 pl. C. A. Reitzel: Copenhagen; Humphrey Milford: London, 1928.—The work forms the first part of a planned monograph of the whole class of the Echinoidea, treating both the recent and fossil forms. The first volume, dealing with the Cidaroidea, comprises the families Archaeocidaridae and Cidaridae. The latter family is divided into the subfamilies Streptocidarinae, comprising some Triassic forms with more or less bevelled plates, the Diplocidarinae, comprising the forms with the pores arranged in double series (*Diplocidaris* and *Tetracidaris*), and the Stereocidarinae comprising all the numerous recent forms and the bulk of the fossil forms. A main point in the classification adopted is that the author does not accept the pluriseriate Palaeozoic forms (Perischoechinoidea) as a natural group in contradistinction to all the rest of the echinoids, from Trias to Recent. The Archaeocidaridae are regarded as closely related to and predecessors of the cidarids, the lepidocentrids as ancestors of the Diadematids. Further, *Bothriocidaris* is rejected as an echinoid genus, its ancestors being among the primitive edrioasteroids, like *Stromatocystis*. Of all the recent forms (about 150 spp. and vars.) detailed descriptions are given, with figures of structural details. Of the fossil forms all the genera are described and figures given of a few of the more characteristic spp. The general morphology of the cidarids—test, spines, pedicellariae, internal anatomy—is dealt with in an introductory chapter; their geographical distribution in a concluding chapter. No new names are introduced in this work, the names of the new genera, species, etc., having been given in a preliminary paper ("New Cidaridae," Vid. Medd. Dansk Naturh. Foren. Bd. 85. 1928).—*T. Mortensen.*

8543. **OPITZ, RUDOLPH. Seelilien aus den Dachschiefern des Hunsrücks.** *Natur u. Mus.* [*Frankfurt a/M*] 61(4): 163-168. 5 fig. 1931.—Illustrations of fossil *Agriocrinus frechi*, Thallocrinus hauchecornei**, and *Codiacrinus schultzei**.

8545. **PANNING, A. Zur Kristalloptik der Kalkkörper der aspidochiroten Holothurien.** *Mitteil. Zool. Staatsinst. u. Zool. Mus., Hamburg* 44: 47-56. 17 fig. 1931.—A discussion of axial and plane symmetry of the calcareous spicules of the cutis, and the podial plates in *Holothuria grisea** and *Stichopus fuscus**.

8546. **PANNING, A. Die Gattung Holothuria. (1. Teil.)** *Mitteil. Zool. Staatsinst. u. Zool. Mus., Hamburg* 44: 91-138. Map, 21 fig. 1929.—The first part of a monograph of the genus *Holothuria* with extensive bibliography, check list with synonymy, and redescriptions of 21 spp., 20 of which are illustrated.

8547. **RUNNSTRÖM, JOHN. Züchtung der Echinodermen. In: EMIL ABDERHALDEN. Handbuch der biologischen Arbeitsmethoden.** Abt. IX. **Methoden der Erforschung der Leistungen des tierischen Organismus.** Teil 5, Heft 3. **Methoden der Meerwasserbiologie.** Lief. 278. p. 403-420. 2 fig. Urban & Schwarzenberg: Berlin, 1928.—Description of protoplasmatic maturation and of the methods of artificial fertilization of the eggs. This is simple in Echinoidea, even in forms with eggs with large yolks, but also can be effected in Asteroidea with small transparent eggs if sufficient alkalinity of the water is maintained. In Asteroidea, with eggs with large amounts of yolk, artificial fertilization has not been successful. In Ophiuroidea and Holothurioidea artificial fertilization has not been successful or has generally produced abnormal larvae. A detailed account is given of the rearing of the larvae and the methods used in obtaining suitable food. A short description is appended on the keeping of adults. —*C. R. Boettger.*

MOLLUSCA

8548. **ADKINS, W. S. New rudistids from the Texas and Mexican Cretaceous.** *Univ. Texas Bull.* 3001. p. 77-100. 7 pl. 1930.—The following spp. are reported from the Edwards (Albian) formation: *Eoradiolites,* emended description, with key to spp. and discussion of developmental stages and life habits; *E.* **quadratus*** (p. 80); *E.* **angustus*** (p. 83); *E. davidsoni* (Hill); *Praeradiolites* **edwardsensis*** (p. 92). From the Taylor and Mendez (Santonian) formations: *Durania* **terlinguae*** (p. 94), Austin chalk equivalent; *D.* **aquilae*** (p. 95), Mendez red foraminiferal clay, Tamaulipas, Mexico. *D.* **huasteca*** (p. 96) and *Sauvagesia* **morgani*** (p. 98), Mendez formation, Tamaulipas, Mexico. Austin chalk spp. *S.* aff. *degolyeri; S.* **acutocostata*** (p. 99). All forms from Texas unless otherwise stated. Types in Bureau of Econ. Geol., Univ. Texas.

8549. **AGUILAR-AMAT, J. B. de. Observaciones malacológicas. VI. Algunos moluscos de Cofrentes y de Játiva. [Mollusks of Cofrentes and Jativa, Spain.]** *Butl. Inst. Catalana Hist. Nat.* 8(8/9): 142-143. 1928.—An annotated list of 9 spp.

8550. **BARGMANN, HELENE E. The morphology of the central nervous system in the Gastropoda Pulmonata.** *Jour. Linnean Soc.* [*London*] *Zool.* 37(250): 1-59. 5 pl. 4 fig. 1930.—The gastropod central nervous system consists of paired buccal, cerebral, and pedal ganglia, with a chain of visceral ganglia. Primitively these ganglia are distinct, connected by nerve cords, and the spiral form of the body has produced a twisting of the visceral chain (chiastoneury). Specialization produces fusion of the ganglia and the chiastoneury may be lost. In pulmonate gastropods 8 types of arrangement of the visceral ganglia are found: (1) Basommatophoran (5 visceral ganglia slightly separated); (2) zonitoid (5 ganglia, touching but distinguishable); (3) orthurethran (4 ganglia, right parietal and abdominal being fused);

(4) heliciform (4 ganglia, left parietal fused with abdominal); (5) *Hygromia* (3 ganglia, left parietal fused with abdominal and right parietal with right pleural); (6) *Ennea* (3 ganglia, both parietals fused with abdominal); (7) *Onchidium* (3 ganglia, parietal fused with pleural); (8) *Vaginula* (all visceral ganglia fused). The groups belonging to each type are distinct when young as well as when adult, despite individual variation and obscuring of the relations by a connective tissue sheath. The identity of the ganglia can often be determined only by the distribution of the nerves, and some forms are difficult to classify. These groups fit only in a general way into Pilsbry's classification. The condition of the nervous system gives valuable evidence regarding relationships of families and genera, and the existing classifications based on one or 2 organ systems may involve serious contradictions.—*E. H. Craigie.*

8551. **BAUMBERGER, E. Beitrag zur Kenntnis der Garnierien aus der schweizerischen und französichen Unterkreide.** *Eclogae Geol. Helvetiae* 21(1): 218-226. 1 pl. 6 fig. 1928.—Seven species of *Garnieria* are described, including *G.* verrienensis* (p. 219), *G.* sequanensis* (p. 221), *G.* stenothalamia* (p. 222), and *G.* paradiscus* (p. 223).—*W. Berry.*

8553. **COOKE, C. MONTAGUE Jr., and HENRY E. CRAMPTON. New species of Partula.** *Bernice P. Bishop Mus. Occasional Papers* 9(11): 3-9. 1 pl. 1930.—*P.* cytherea* (p. 3), Tahiti; *P.* lanceolata* (p. 5), Fiji; *P.* thurstoni* (p. 6) and *P.* montana* (p. 7), Samoa.

8554. **COUTAGNE, GEORGES. La faune malacologique de la Tarentaise.** *Ann. Soc. Linnéenne Lyon* 74: 7-79. 1928(1929).—An annotated list is given of the mollusks which occur in the rather isolated valley which forms the basin of the Isère above Albertville, Savoie, France. —*H. B. Baker.*

8555. **EHRMANN, PAUL. Zur Kenntnis von Chondrina avenacea (Brug.) und ihren nächsten Verwandten.** *Arch. Molluskenk.* 63(1): 1-28. 1 pl. 1931.—Because Draparnaud's original specimens of *Pupa avena* are identical with Küster's *P. cereana*, the author decides that both are synonyms of *Chondrina avenacea* (Brug.) and replaces Küster's restricted *avenacea* with *C. clienta* (Westerlund). *C. avenacea* istriana (p. 23), Italy.—*H. B. Baker.*

8556. **FRASER, C. McLEAN. The razor clam, Siliqua patula (Dixon), of Graham Island, Queen Charlotte group.** *Trans. Roy. Soc. Canada, Sect. 5, Biol. Sci.* 24 (1): 141-154. Map, 5 pl. 1930.—Collections made in July in 8 different locations in a 17-mile stretch of sandy beach included specimens of each year class up to the 9-year class. The uniformity in growth rate in the different year classes indicates a greater uniformity in environmental conditions from year to year than is found in parts of the coast where other species of clams are obtained commercially. Spawning had started only at the western end of the beach on July 5, but was general throughout the whole length of the beach by July 21. The minimum temp. for spawning is about 13°. After a spell of cool weather when the temp. was considerably below 13°, it reached that point again on July 18 and continued at that temp. or higher for some days. No 2-year clams were matured or nearly maturing but 86.6% of the 3-year clams were. Those that were not were all the smaller members of the class. The Graham Islands clams are exploited only by 1 packing company that has been in yearly operation since 1924. The method of digging and collecting is not liable to be so injurious as the methods used in digging other clams.—*Author's summary.*

8557. **GAMBETTA, L. I Gasteropodi raccolti dall'Ing. C. Crema in Cirenaica. [Gastropods collected by C. Crema in Cirenaica.]** *Boll. Mus. Zool. ed Anat. Comp. R. Univ., Torino* 40(Paper 35): 1-6. 1925(1926).—A list of 13 spp. from 8 families, including *Clausilia* bengasiana Monts. (in sch.) (p. 4), and *Melania* (*Melanoides*) *tuberculata*, first record for Cirenaica.

8558. **GRIMPE, GEORG. Pflege, Behandlung und Zucht der Cephalopoden für zoologische und physiologische Zwecke.** In: **EMIL ABDERHALDEN. Handbuch der biologischen Arbeitsmethoden. Abt. IX. Methoden der Erforschung der Leistungen des tierischen Organismus. Teil 5, Heft 3, Methoden der Meerwasserbiologie.** Lief. 278. p. 331-402. 7 fig. Urban & Schwarzenberg: Berlin, 1928.—General and critical account of the methods, experiments, and observations in keeping and breeding Cephalopoda in captivity, based on personal experience and on that of others. Most of the forms which can be kept in captivity are littoral, especially benthonic species such as *Octopus*, *Eledone*, *Sepia*, *Sepiola*, etc., but also nectobenthonic neritic species as *Loligo*, *Sepioteuthis*, *Alloteuthis*, etc., which, however, are less easily kept. The technique of the aquarium and methods of keeping the animals are described and special directions for particular species discussed. *Octopus vulgaris* Lam., *Eledone moschata* Lam., and *Sepia officinalis* L., are more extensively treated. Directions are given for the rearing of cephalopods from the egg, including the rearing apparatus for eggs and larvae.—*C. R. Boettger.*

8559. **HATT, PIERRE. L'absorption d'encre de Chine par les branchies des Diotocardes. Existence d'un canal cilié particulier.** *Bull. Soc. Zool. France* 52: 179-184. 4 fig. 1927.—In *Trochocochlea turbinata* after 24 hrs. in sea-water containing Chinese ink, a row of black spots appear along the efferent face of the gill, one spot in each lamella. At this spot there occurs a short ciliated canal, with an exterior opening to which ciliated currents are directed by the cilia. The wall of this canal consists in part of ciliated and in part of non-ciliated cells; the latter take up the ink particles, also dyes. Similar ciliated canals in the gills were found in *Haliotis*, *Emarginula*, and *Fissurella*, and probably exist in general in the Diotocardia, especially in the Rhipidoglossa. They do not occur in a large number of Monotocardia examined.—*L. H. Hyman.*

8560. **HINARD, GUSTAVE, et LOUIS LAMBERT. Contrôle sanitaire ostréicole. Tableau de l'ostréiculture française.** *Rev. Trav. Office Pêches maritimes (Paris)* 1(3): 37-90; (4): 61-127. 35 fig. 1928.—Part I.—The basis of the technique of oyster culture. Discussion of the methods of breeding, raising and harvesting of oysters (*Oystrea edulis** and *Gryphaea angulata**). A résumé of recent scientific works with regard to their technical application. Pt. II.—Oyster culture establishments. Description and criticism of the principal types of French establishments. The apparatus varies according to the region and the particular situation (shaking, submerged, non-submerged, etc.), but general rules can be formulated especially for healthful installations. They must be protected from polluted water. Pollution is prevented by installing artificial oyster beds or basins removed from all sources of contamination either by elevating them and admitting free-flowing water, by purifying the water in reservoirs by decantation or by filtration. The final washing, storage, and packing necessitate great care and the methods used to escape contamination are described. The plan of a model oyster-culture establishment is given, showing arrangement recommended for the basins, washers, location of shipping points and accessories. The Office of Sea Fisheries controls all French establishments and prescribes rules for obtaining sanitation certificates required of all who ship oysters for human consumption. (Decree of July 31, 1923.) Pt. III.—Natural resources and their exploitation. Condition of natural oyster beds. Description of regions of oyster-culture. Most of the native oyster beds (*Ostrea edulis*) have suffered greatly in recent years from a disease of unknown cause. Some are recovering, but slowly. This recovery has been helped by severe regulation. At the present time only a few beds on the banks of the Morbihan are reasonably productive. The oysters anchor themselves on artificial tiles, are collected and reared in basins, then sent to centers for sorting or fattening (Marennes, Belon). The formerly prosperous oyster beds of Cancale, Brest, and Arcachon now furnish but small quantities. The beds of the Portuguese oyster (*Gryphaea angulata*) have suffered much less from natural causes, but they are in danger

of unreasonable exploitation and protective measures are needed. The productive area extends from La Rochelle to Arcachon; at present the basin of Arcachon is the greatest center of production thanks to the use of artificial tiles. The Portuguese oyster, at Arcachon and especially at Marennes, is well cared for by methodical cultivation in basins. The oyster basins (not considering the natural beds) comprise more than 5,000 hectares and are increasing every year. At the present time, there are about 25,000 establishments for cultivation and 700 shipping points. The areas given over to oyster-culture cover approximately 700 hectares in the Morbihan, 400 in the maritime region of La Rochelle, 3,000 in the region of Marennes and 1,050 in the basin of Arcachon. —*G. Hinard (transl. by E. R. Smith)*.

8568. **OHSHIMA, HIROSHI. On Entovalva semperi Ohshima, an aberrant commensal bivalve.** [In Japanese, with English abstract.] *The Venus* [*Japan*] 2(4) : 161-177. 1931.—A further detailed description of the animal is here given. The synaptid *Protankyra bidentata* (Echinodermata), whose length may attain 30 cm., lives in a tube lying nearly horizontally about 8-10 cm. below the surface of the muddy bed. Usually only one *Entovalva* is found attached to the host, and from among 134 synaptids collected and examined, 53 of the commensals were found. The mollusk *Montacuta,* the crustacean *Hexapus,* and 3 spp. of polychaetous annelids are also often found living with this synaptid as commensals. Hakosaki near Fukuoka, of Hakata Bay of northern Kyushu, is added, besides Tomioka of Amakusa, as another habitat of this bivalve. *Entovalva semperi* in situ does not move actively, but if removed from the host it creeps about, often with a regular rhythm of contraction and extension of the foot and body. The whole surface of the creeping sole seems to act as sucker, but hardly any scar is left on the skin of the synaptid if forcibly detached from it. Internal anatomy of each organ as studied from sections is described in detail, and is compared with the accounts of *Entovalva mirabilis* and *perrieri* given by Voeltzkow, Malard, Anthony, Nierstrasz, etc. No individual with testis has yet been examined, so that it is not decided whether the animal really is hermaphroditic. Malard's suggestion that the food may be taken in through the byssal papilla, and Anthony's idea of incipient division of the siphonal orifice, are both disproved. The presence of teeth in the valves of *mirabilis* and *Devonia donacina* makes the interrelations of these allied forms rather intricate, but for the present the author prefers to retain the genus *Entovalva* to comprise the 3 species, *mirabilis, perrieri,* and *semperi.—Author's abstract.*

Pomatiasidae: *Parachondria* **pyrostoma*** (p. 259), St. Andrew Isl. Types of new species and subspecies in Acad. Nat. Sci. Philadelphia.—*H. A. Pilsbry.*

8575. [POPOV, K. K.] ПОПОВ, К. К. К распространению и экологии **Limnaea truncatula Müll.** на С. Кавказе. **[Distribution and ecology of L. truncatula in north Caucasus.]** [German summary.] Работы Северо-Кавказской Гидробиологической Станции. (*Trav. Sta. Biol. Caucase du Nord*) 3(1/3) : 155-164. 1930.—This species is abundant in the foothills and mountains up to 2000 m. It inhabits chiefly temporary bodies of water, also sluggish brooks. It occurs isolated or in company with other mollusks, *Planorbis planorbis* and *Pisidium casertanum*. When the water basins dry up, it attaches itself to water plants, and covers its oral aperture with a thin membrane, or bores into the mud without covering its oral aperture. Three periods of egg-laying were noted in the summer of 1929, the complements varying from 7 to 23. In one place used as a sheep pasture, 2 out of 200 dissected mollusks were infested with parthenogenetic forms of the trematode, *Fasciola hepatica.—From author's summary.*

8576. RENSCH, BERNHARD. Über einige aberrante Landschnecken und die Abgrenzung der Familien bei Pulmonaten. *Zool. Anz.* 92(7/8) : 181-187. 3 fig. 1930.—**ARIOPHANTOPSIS** (p. 181), near *Sasakina*, type *A.* **pseudoamphidromus*** (*Ariophanta p.* Rensch) (p. 183); **SASAKINA** (*Sasakia* Rensch, not Moore) (p. 182). A comparison of the characters of the genera *Ariophanta**, *Sasakina**, *Ariophantopsis**. *Pseudopartula**, and *Amphidromus** shows the difficulty of separating the families Pleurodontidae and Ariophantidae. *Sasakina* and *Ariophantopsis* are placed in a special group, **SASAKINAE** (p. 186), and referred provisionally to the Ariophantidae. The genera *Chloritis* and *Landouria* and their relatives are considered Eulotidae. More exact study of the genera and spp. of the Pulmonata must lead to a reduction of the limits of some of the families.

8577. RENZ, CARL von. Frechiellen, Leukadiellen und Paroniceraten im westgriechischen Oberlias mit tessinischen Vergleichsstücken. *Eclogae Geol. Helvetiae* 20(3) : 422-444. 1 pl. 10 fig. 1927.—Describes 2 spp. of *Frechiella* including *F. fulviae* v. **luganensis*** (p. 428) from Breggia Gorge, Switzerland; 2 spp. of *Leukadiella*, including *L.* **jeanneti*** (p. 432), Epirus, Greece; and 4 spp. of *Paroniceras.—W. Berry.*

Australia. Type in Brit. Mus. The relationship of the 3 genera is discussed. 8.—A revised list of genera and subgenera recognized by the author, with citations of type species. Octopodidae: [*Octopus*] *Macrotritopus* [subg.] **equivocus** (*O. gracilis* Verrill, not Eydoux & Souleyet) (p. 607); **JOUBINIA** (p. 607), type *J.* **fontaniana** (d'Orb.), n. comb. (p. 607); **MACROCHLAENA** (p. 607), type *M.* **winckworthi** (Robson), n. comb. (p. 607); **HAPALOCHLAENA** (p. 608), type *H.* **lunulata** (Quoy & Gaim.), n. comb. (p. 608); **TERETOCTOPUS** (p. 608), type *T.* **indica** (*"Polypus pricei"* Massy, 1916, not Berry) (p. 608). 9.—The author lists specimens of 8 spp., with locality data, and gives descriptive notes on *Octopus vulgaris, O. rugosus,* and *O. macropus** (?). *O.* **briareus*** (p. 612), Caribbean; *Enteroctopus* **juttingi*** (p. 616), Patagonia. Types in Zoöl. Mus., Amsterdam. 10.—*Enteroctopus megalocyathus* [author ?] (=*Octopus patagonicus* Lönnberg) is considered distinct from *E. eureka* Robson. 12.—Descriptive notes on young specimens from the N. Atlantic and E. Pacific, belonging apparently to 5 different spp. of *Octopus,* but not determined specifically.

8579. SEKI, H. Identification on the larva of Ostrea denselamellosa Lischke. [Japanese, with English summary.] *Jour. Imp. Fisheries Exp. Station, Tokyo* 1(1, pt. 1) : 233-240. 2 pl. 1930.—This oyster has not yet been cultivated, owing to the impossibility of collecting spats. The author obtained many straight-hinged larvae from the adult and reared them from July to Sept. In August many were full-grown. The larval development was traced accurately, and means were found for distinguishing between the larvae of *Ostrea denselamellosa** and *O. futamiensis**.

8580. SETNA, S. B. The neuro-muscular mechanism of the gill of Pecten. *Quart. Jour. Microscop. Sci.* 73(3) : 365-391. 3 pl., 4 fig. 1930.—*Pecten* responds to all forms of stimulation by snapping the shell. Before the adductor muscle contracts, the gill shortens (but not if the branchial nerve is cut near its origin) so that it lies safely within the valve margins. The gill muscles relax immediately after the adductor. Excised gills continue very sensitive to stimuli for 2-3 days. If the gill is cut vertically along its length into several pieces, each piece responds like the entire gill. This is almost certainly due to a local nervous mechanism, presumably a nerve-net. If the gill is stimulated mechanically, the frontal surfaces of the 2 lamellae approach each other, the movement often being executed by the lamella which was not touched. Each principal filament is able to move the attached ordinary filaments. This flapping movement is due to the action of interfilamentary junctions. When weak, irritating solutions were applied to the regions of the osphradial ridge there was a slight response. Other parts of the gill were much less sensitive to stronger solutions. Sea water and star-fish extract induced no noticeable response. Thus it is evident that the gill is sensitive to chemical stimulation and by means of the osphradium capable of detecting slight changes in the surrounding medium. The axis and principal filaments have what appears to be a true nerve-net. The gills receive nerve-fibers from the visceral ganglion and also, through the hitherto unknown subsidiary branchial nerve, from the brain. The osphradium is much more extensive than has previously been supposed. Two sets of muscles (non-striated) at the base of the filaments are responsible for movements of the lamellae. The principal filaments are connected to the ordinary filaments by processes containing true muscle-cells and by these cells movements of the filaments are effected.—*J. S. Gutsell.*

8581. SPATH, L. F. A monograph of the Ammonoidea of the Gault. Vol. I, pt. V & VII. (Continuation & conclusion.) In: *Palaeontographical Soc. [London]* **79** (paper 1) : 187-206. Pl. 17/20, 8 fig. 1925(1927); **82** (paper 2) : i-x+267-311. Pl. 25/30, 16 fig. 1928(1930).—Old species are discussed and figured. Descriptions of new species in the text are in most cases supplemented by plate- and figure-explanations. *Epihoplites* **iphitus*** (p. 187), Devon, Up. Gault, type in Brit. Mus.; *Callihoplites catillus**; *C.* **patella*** (p. 192), Wilts, Up. Gault, type in M. P. G. (Mus. Practical Geol.); *C.* **strigosus*** (p. 194), Wilts, Malmstone, Up. Gault, type in B. M.; *C. s.* var. **cristata*** (p. 195), Wilts, Malmstone, type in M. P. G.; *C.* **formosus*** (p. 196), Wilts, Up. Gault, type in B. M.; *C. auritus**; *C.* **horridus*** (p. 200) and *C.* **variabilis*** (p. 202), Wilts, Up. Gault, type in M. P. G.; *C.* **potternensis*** (p. 203), same as the preceding, type in B. M.; *C.* **tetragonoides*** (p. 204), Oxford, Up. Gault, type in M. P. G.; *C.* **seeleyi*** (*Pleurohoplites s.* Spath) (p. 205); *Euhoplites subtabulatus**, *E. aspasia** and var. **cantiana*** (p. 269), Kent, Lr. Gault, type

in author's coll.; *E. loricatus* v. **meandrina*** (p. 271), Kent, Lr. Gault, type presumably in author's coll.; *E. pricei**, *E. subtuberculatus**; *E.* **opalinus*** (*Ammonites tuberculatus* J. Sowerby not Smith) (p. 274); *E. bucklandi**; *E. nitidus**; *E. proboscideus** and v. **intermedia*** (p. 282), Kent, type in author's coll.; *E. p.* var. **ultima*** (p. 282), Devon, Up. Gault; *E. armatus**; *E.* **trapezoidalis*** (p. 285), Norfolk, Red Chalk, probably base of Up. Gault, type in Sedgwick Mus.; *E. t.* var. **formosa*** (p. 285), Kent, Lr. Gault, type in author's coll.; *E. t.* var. **micheliniformis** (p. 286), locality not stated; *E.* **serotinus*** (p. 286), Kent, Up. Gault, type in author's coll.; *E. solenatus**, *E. ochetonotus** v. **nodosa** (p. 289) and *E. sublautus** v. **monacantha*** (p. 290), Norfolk, Red Chalk, Up. Gault, type in Sedgwick Mus.; *E. suberenatus**; *E.* **inornatus*** (*Ammonites crenatus* Sowerby not *crenata* Bruguière) (p. 293); *E. vulgaris**; *E. boloniensis**; *Discohoplites caelonotus**; *D. varicosus**; *D. subfalcatus*; *D. valbonnensis**; *D.* **anomalus*** (p. 304), Dorset, Uppermost Gault ("Upper Greensand"), type in Grimsdale coll.; *D.* (*Hyphoplites?*) **transitorius*** (p. 304), Dorset, Uppermost Gault) type in Grimsdale coll. The present paper concludes the descriptions of the hoplitid ammonites of the Gault, in 7 pts., comprising vol. I. Systematic and alphabetic indexes are given.

8582. TOMLIN, J. R. le B. On South African marine Mollusca, with descriptions of new genera and species. *Ann. Natal Mus.* 6(3): 415-450. 1 pl. 1931.—This is a continuation of a faunistic list, the last previous part of which appeared in the same journal in 1926. [See B. A. 2(3/5): entry 7831.] About 147 spp. are listed, with locality records and taxonomic remarks. Patellidae: *Patella granatina* L. is designated as the type of *Patellona* Thiele; *Patellopsis* Thiele is preoccupied by *P.* Nobre; *Patella variabilis* v. **polygramma** (*P. v.* var. *radiata* Krauss, not *P. r.* Born) (p. 418); *P. v.* var. **fasciolata** (*P. v.* var. *fasciata* Krauss, not *P. f.* Gmelin) (p. 418). Trochidae: *Oxystele variegata* (Anton) (=*Trochus impervius* Menke); *O. sinensis* (Gmelin) (=*Trochus merula* Lamarck); [*Calliostoma*] *fultoni* (Sow.) (=[*Trochus?*] *farquhari* Sow., *Trochus stenomphalus* Sow.). Turbinidae: *Phasianella* **tropidophora*** (p. 420), Cape Province. Littorinidae: *Littorina coccinea* (Martyn) (=*L. limax* Gray, *L. glabrata* Philippi, *L. laevis* Philippi, *L. obesa* Sow.). Rissoidae: *Alvania* **kowiensis** (*A. ima* Bartsch, 1915, not Bartsch, 1911) (p. 421); *A.* **outis** (*A. nemo* Bartsch, 1915, not Bartsch, 1911) (p. 421). Rissoinidae: *Rissoina* **leucophanes*** (p. 421) and *R.* **jeffreysiensis** (p. 422), Cape Prov. Cerithiopsidae: **SEILOPSIS** (p. 424), erected for *Cerithiopsis ? peilei* Smith. Triphoridae: *Triphora* **alexandri*** (p. 425), *T.* **hemileuca*** (p. 426), and *Euthymia* **latisinuata*** (p. 426), Natal. Turritellidae: *Turritella ferruginea*, of hitherto unknown locality, recorded from off Cape Prov., 30-250 fms. Calyptraeidae: *Calyptraea* **capensis*** (p. 428), Cape Prov. Buccinidae: [*Bullia ?*] *mozambicensis* Smith (=*Bullia pustulosa* Sow.). Fasciolariidae: *Latirus alboapicatus* Smith, emended description. Pyrenidae: *Pyrene* **retiaria*** (p. 436), Natal; *Anachis kraussii* Sow. (=*Columbella io* Bartsch, *C. alfredensis* Bartsch); the author points out that *Columbella adjacens* Smith, 1904, is a nomen nudum, and likewise, apparently, *C. capensis* Smith, as recorded by Bartsch, 1915. Turridae: *Clionella sinuata* (Born) (=*Buccinum phallus* Gmelin, *Pleurotoma buccinoides* Lam., *P. bornii* Smith, *Clionella turtoni* Bartsch); *C. caffra* (Smith) (=*Drillia praetermissa* Smith, *D. nivosa* Smith). Veneridae: *Tivela hartwigii* Dunker (=*T. rejecta* Smith). Cardiidae: **AFROCARDIUM** (p. 449), n. subg. of *Fragum*, type *F.* (*A.*) **shepstonense*** (p. 449), Natal.

8583. TOMLIN, J. R. le B. Some preoccupied generic names. III. *Proc. Malac. Soc. London* 19(4): 174-175. 1931.—**HANNAOCERAS** (p. 174), new name for *Smithoceras* Hanna (not Diener), type *Ammonites nasturtium* Dittmar; **DIAPHANOTEUTHIS** (p. 174), n. n. for *Leptoteuthis* Verrill (not Orb.), type *L. diaphana* Verrill; **HARMERIA** (p. 174), n. n. for *Lacunopsis* Harmer (not Desh.), monotype *L. obtusus*; **ALLOMACTRA** (p. 175) subg., n. n. for the subg. *Heteromactra* Cossmann (not Lamy), type *Mactra grateloupi* Desh.; **BOYCOTTIA** (p. 175), n. n. for *Donaldia* Perner (not Alluaud), type *D. altera* Pern.; **CYRTODONTULA** (p. 175), n. n. for *Whitella* Ulrich (not Spinola), type *W. obliquata* Ulr.; **PLATYCHELYNE** (p. 175), n. n. for *Platychilus* Wöhr. & Koken (not Yakobley), type *Platychilus wöhrmanni* Koken; **TRYPANOCOCHLEA** (p. 175), n. n. for *Verania* Koken (not Vérany), type *V. cerithioides* Koken; **TOROTEUTHIS** (p. 175), n. n. for *Hyaloteuthis* Pfeffer (not Gray).—*H. B. Baker.*

8584. TRAUTH, FRIEDRICH. Aptychenstudien. I. Über die Aptychen im Allgemeinen. II. Die Aptychen der Oberkreide. *Ann. Naturhist. Mus. Wien* 41: 171-259. 8 fig. 1927; 42: 121-193. 3 pl. 1928.—In Part I the history of the attempt to locate the aptychus systematically, culminating in the discovery that it is the operculum* of the ammonite shells, is discussed in detail. The aptychi are quite important in palaeontological research. The morphology is studied in detail and is accompanied by a glossary of synonymy of all descriptive terms used by other authors. The name *Aptychus* Meyer has been ranked as a genus since 1829. As in other groups where species are first known from a part or a developmental stage, a group of provisional generic names are introduced by Trauth under the name "typus" (n. typ.), and his new species under the name "formnamen" (n. f.). In referring an aptychus to its proper generic and specific position a notation such as "*Aptychus* ad: *Scaphites spiniger* Schlüt." is used. A complete new series of classificatory names is introduced as follows: **PALANAPTYCHUS** (p. 214) (ad: palaeozoic Goniatitidae); **PALAPTYCHUS** (p. 214) (ad: mesozoic Goniatitidae); *Anaptychus* Opp. (ad: *Arcestes, Psiloceras, ? Aegoceras, Arietites, Amaltheus*); **CORNAPTYCHUS** (p. 228) (group "Cornei" Voltz, ad: *Harpoceras, Hecticoceras, Sonninia, Dumortieria*); **LAMELLAPTYCHUS** (p. 228) (group "Imbricati" Voltz, ad: *Oppelia* pro parte, ? *Oecotraustes, Haploceras* p. p.); **PUNCTAPTYCHUS** (p. 228) (group "Punctati" Zitt., ad: ? *Oppelia* p. p., ? *Haploceras* p. p.); **GRANULAPTYCHUS** (p. 228) (group "Papillosi" Menegh. et Bornem., ad: *Stephanoceras, Perisphinctes, ? Holcostephanus*); **LAEVAPTYCHUS** (p. 228) (group "Cellulosi" Voltz, ad: *Aspidoceras*=*Waagenia* Neum., ? *Simoceras*); **PRAESTRIAPTYCHUS** (p. 230) (ad: *Parkinsonia, ? Cosmoceras, Kepplerites*); **PTERAPTYCHUS** (p. 232) (ad: ? *Desmoceras*), for *Aptychus numida* Coqu.; **SPINAPTYCHUS** (p. 232) (ad: ? *Mortoniceras*), for *Aptychus spinosus** Cox; **LISSAPTYCHUS** (p. 231) (ad: ? *Parapuzosia*), for *Aptychus leptophyllus**; **STRIAPTYCHUS** (p. 229) (group "Coalescentes" Zitt., ad: *Scaphites*); **PSEUDOSTRIAPTYCHUS** (p. 229) (ad: ? *Pachydiscus, Parapachydiscus*); **RUGAPTYCHUS** (p. 228) (group "Rugosi" Menegh. et Bornem., ad: *Baculites*); **CRASSAPTYCHUS** (p. 232), for *Aptychus crassus** Héb. *Aptychus lamellosus* Park. is referred to *Lamellaptychus* (p. 223), *A. carbonarius* Koen. and *A. gallienneanus* Orb. to *Palaptychus* (p. 235). The following names become established in part 1 (1927) as new names for figured aptychi in quoted works, and in part 2 are described with full synonymy and often illustrated: *Striaptychus cretaceus* v. **excentrica*** (p. 243); *S.* **cheyennensis*** (p. 243); *S.* **leopolitanus** (p. 243); *S.* **radiosus** (p. 243); *S.* (?) **ravnii*** (p. 244); *S.* **roemeri*** (p. 244); *S.* **schlüteri*** (p. 244); *S.* **sharpei** (p. 244); *S.* **spinigeri*** (p. 244); *S.* **strehlensis** (p. 244); *S.* **vinarensis** (p. 244). The following forms are transferred in part 1 and redescribed in part 2: *Striaptychus* **complanatus*** (*A. c.* Fr. et Schlg.) (p. 243); *S.* **cretaceus** (*A. c.* Münst.) (p. 243); *S. c.* var. **convexa*** (*A. convexa* Roem.) (p. 243); *S.* (?) **obtusus*** (*A. o.* Héb.) (p. 243); *S.* (?) **planus*** (*A. p.* Fritsch) (p. 243); *S.* **radiatus*** (*A. r.* Fric) (p. 243); *S.* (?) **simplex*** (*A. s.* Fritsch); *S.* (?) **verrucosus*** (*A. v.* Fritsch); *Lissaptychus* (?) **cretaceus***

(*A. c.* Gein. part.) (p. 244); *Rugaptychus* **rugosus** (*A. r.* Sharpe) (p. 245); *R. r.* var. **insignis*** (*A. i.* Héb.) (p. 245); *R.* **knorrianus*** (*A. k.* Diener); *R.* **flexus*** (*A. f.* Mobg.). Part 1 closes with a phylogenetic table of the families and new provisional genera (typi) and a long bibliography. The illustrations indicated above are in part 2. Part 2 (1928) contains the descriptions of all provisional genera (typi) and aptychus species (forms) with complete synonymy of each. The new forms and synonymy are as follows: *Rugaptychus rugosus** Sharpe (=*Aptychus stobaei* Diener); *Aptychus peramplus* is referred to *Rugaptychus* (p. 128); *Striaptychus cretaceus* v. **leopolitana** (*S. leopolitanus* Trauth) (p. 147); *S. c.* var. **sharpei** (*S. s.* Trauth) (p. 148); *S. c.* var. **radiosa** (*S. radiosus* Trauth) (p. 149); *Pseudostriaptychus* **pseudo-stobaei** (p. 168), aptychus of *Parapachydiscus pseudo-stobaei*; *Ps.* (?) **gollevillensis*** (*Aptychus g.* Sharpe) (p. 168); *P.* (?) **icenicus*** (*A. i.* Sharpe) (p. 170); *P.* (?) **portlocki*** (*A. p.* Sharpe) (p. 171); *Lissaptychus* **teplitzensis** (p. 178), Bohemia; *L.* **conchaeformis*** (*A. c.* Fr.) (p. 179). In addition the author mentions still other Up. Cretaceous fossils wrongly identified as aptychi, namely several lamellibranchs, and *Sidetes* Giebel, which is probably the upper maxilla of a cephalopod. By far the greater number of aptychi considered came from the European Up. Cretaceous, for the most part from the Senonian and Turonian of that region; and only occasionally from the Cenomanian (*Lissaptychus* (?) *cretaceus*). *Spinaptychus* has been recorded also from the Senonian of England and from Palestine. From America there are known only *Striaptychus cheyennensis* (Fox Hills group, Senonian, of Dakota) and *Striaptychus* f. 1 (Eagle Sandstone group, Senonian, of Wyoming).

8585. UTTERBACK, W. I. Phylogeny and ontogeny of Naiades. *Proc. West Virginia Acad. Sci.* 2: 60-67. 1928.

8586. VĂSCĂUȚANU, TH. Fauna argilelor sarmatice dela Ungheni. [The Sarmatian shale fauna of Ungheni.] *Anuar. Inst. Geol. Românici* 13: 85-120. 2 pl., 7 fig. 1928 (1929).—The author reports 4 Rhizopoda, 2 Vermes, 2 Bryozoa, 27 Lamellibranchiata, 15 Gastropoda, 2 Crustacea, and 2 Vertebrata, from the Neogene, including: (Lamellibranchiata) *Mactra* **cobalcescui*** (p. 90); *Cardium* **simionescui*** (p. 100); *C.* **ungheniensis*** (p. 103); *C.* **elisabetae*** (p. 103).

8587. VAYSSIÈRE, A. Étude zoologique et anatomique sur quelques Gastéropodes Prosobranches provenant des Campagnes du Prince Albert Ier de Monaco. *Résultats Campagnes Sci. Albert I Prince de Monaco Fasc.* 80. 3-26. 1 pl. 1930.—The author presents detailed anatomical studies of *Trophon dabneyi**, *Bela* **alberti*** (*Pleurotoma a.* Dautz. & H. Fischer) (p. 6), *Clionella* **richardi*** (*Pleurotoma r.* Dautz. & H. Fischer) (p. 7), *Turcicula alicei**, *Caecum trachea**, and *C. vitreum**. There is also some taxonomic discussion of these forms. *Clionella* Gray is raised from subgeneric to generic rank. Previous work on the genus *Sinusigera* is reviewed, and the following new spp. are described: *S.* **dautzenbergi*** (p. 24), *S.* **richardi*** (p. 25), and *S.* **sirventi*** (p. 26), all from near the Azores, at the surface; types in Mus. Océanog. Monaco.

8588. VINCENT, EMILE. Les Mytilidées des sables de Wemmel (Eocène supérieur). *Bull. Mus. Roy. Hist. Nat. Belgique* 6(17): 1-9. 3 fig. 1930.—The treatment of the following forms from Belgium includes synonymies, descriptions, and taxonomic discussion: *Modiola wemmelensis; Lithophagus* (*Botula*) **brabanticus*** (p. 2); *Modiolaria seminuda; M. hastata; Arcoperna nuculaeformis; Crenella* **cymbiola*** (p. 7); *C.* **humilis*** G. Vincent ms. (p. 8).

8589. WAGNER, HANS. Morphologische und anatomische Studien an Milax. *Zool. Anz.* 88(1/4): 39-57. 6 fig. 1930.—Color, skin, keel, foot, mantle, shell, radula, and sex organs of this snail genus are discussed. **MACROTYHLACUS** [also given as *Macrothylacus*], n. subg. of *Milax.* with *M.* (*Macrothylacus*) **jablanacensis*** (p. 46); *M.* (*Milax*) **schleschi*** (p. 48). Species of *Milax* are listed with keys to sections and subgenera, and to species found in Hungary and Austria, with a map of localities in Hungary.—*L. H. Hyman.*

8590. WOODWARD, ARTHUR. Shells used by the Indians in the village of Muwu. *Bull. Southern California Acad. Sci.* 29(3): 105-114. 1 pl., 2 fig. 1930.—Eighteen of the mollusks most frequently encountered in a midden excavation on the California coast are listed, with notes on their use as food, ornaments, etc.

8593. CHAMBERLIN, RALPH V. On a collection of chilopods and diplopods from Oklahoma. *Ent. News* 42(4): 97-104. 1 pl. 1931.—List of 15 spp., including *Spirobolus* **oklahomae*** (p. 98), *Orthoporus* **wichitanus*** (p. 99), *Eurymerodesmus* **birdi*** (p. 101), and *E.* **mundus*** (p. 102). Types in author's coll.

8594. KISHIDA, KYUKICHI. A Japanese species of Pauropoda (Neopauropus niwai). *Annot. Zool. Japonenses* 11(4): 377-383. 7 fig. 1928.—**NEPAUROPUS** (p. 377), allied to *Stylopauropus*, type *N.* **niwai*** (p. 377), Honshiu, in author's coll. About 50 spp. of Pauropoda are previously known.

8595. REMY, PAUL. Description d'un nouveau Pauropode de la faune de France (Allopauropus sequanus n. sp.). *Arch. Zool. Exp. et Gén., Notes et Revue* 70 (3): 73-82. 10 fig. 1930.

8596. SCHUBART, OTTO. Über die Diplopodenfauna Pommerns und einiger der Küste vorgelagerter Inseln. *Dohrniana* [*Stettin*] 11: 241-279. 3 fig. 1931.—An annotated list of 32 spp. found in Pomerania, with additional notes on the diplopod fauna of 2 islands—Greifswalder Oie and Hiddensee.

8597. SCHUBART, OTTO. Einige neue Diplopoden von der Insel Korsika und aus Spanien. *Zool. Anz.* 94 (1/2): 2-12. 10 fig. 1931.—*Polydesmus* **corsicus*** (p. 4) and *Archiulus corsicus* ssp. **schulzei*** (p. 5), Corsica; *Polydesmus* **heroldi*** (p. 9), Spain.

8598. VERHOEFF, KARL W. Zur Kenntnis der Geographie und Ökologie der Diplopoden, besonders Nordwestitaliens. 115. Diplopoden-Aufsatz. *Zeitschr. Wiss. Biol. Abt. A, Morph. u. Ökol. Tiere* 17(1/2): 219-261. 1930.—Diplopods were collected from 5 regions in northern Italy: the vicinity of Lake Maggiore; Biellan Alps and Turin Hills; southern Piedmont (Ceva, Mondovi, Cuneo); the Maritime and Ligurian Alps; the Riviera. Characteristic spp. are listed from each region. There are also comparisons with the faunas of the northeastern Alps and of Germany. Evidence as to the origin of these faunas is given.—*A. O. Weese.*

8599. VERHOEFF, KARL W. Pseudopolydesmus "im Wechsel der Zeiten." *Zool. Anz.* 94(11/12): 305-318. 7 fig. 1931.—Discusses the controversy over the separation of *Pseudopolydesmus* from *Polydesmus* and demonstrates

that the former should be suppressed because of identical characters.

8600. **VERHOEFF, KARL W.** Chilopoden der Insel Elba (Isopoden). *Zool. Anz.* 95(11/12): 302-312. 6 fig. 1931.—A list of 27 spp. of Isopoda and 21 spp. of Chilopoda from Elba, with collecting notes on the latter. [Chilopoda] *Lithobius* (*Alokobius*) **elbanus*** (p. 306); *L. microps**; *L. m.* vars. **burzenlandicus** and **ruinarum*** (p. 308); *Geophilus* **ruinarum*** (p. 310).

8601. **WORTHINGTON, E. B.** The Diplopoda and Chilopoda of Wicken Fen. *Nat. Hist. Wicken Fen* Pt. 4. 308-312. 1928.

CRUSTACEA

MARY J. RATHBUN, *Editor*

WALDO L. SCHMITT, *Associate Editor*

CHANCEY JUDAY, C. DWIGHT MARSH, H. A. PILSBRY, CLARENCE R. SHOEMAKER, CHARLES B. WILSON, *Assistant Editors*

(See also in this issue Entries 6183, 6311, 6328, 6332, 6889, 6970, 7799, 8182, 8185, 8188, 8201, 8206, 8215, 8422, 8427, 8488, 8568, 8586, 8600, 8658, 9061)

8602. **BROILI, FERDINAND.** Ein neuer Fund von ? "Megadactylus." *Sitzungsber. Math.-Naturwiss. Abt. Bayerischen Akad. Wiss.* 1930(3): 215-222. 1 pl., 1 fig. 1930.—Malacostraca. Syncarida, **BUNDENBACHIELLUS** (p. 219), n. nom. for *Megadactylus* Broili not Hitchcock, type *B. giganteus* (*M. g.* Broili) (p. 219), is transferred from Myriapoda to Crustacea, as an unnamed group in Syncarida; *B.* (?) **minor*** (p. 219), Lr. Devonian slate of Bundenbach, Hunsrück, Prussia.

8603. **BROOKS, STANLEY T.** List of types of Crustacea in the Carnegie Museum on January 1, 1931. *Ann. Carnegie Mus.* 20(2): 161-167. 1931.—The museum has type material of 25 spp.

8604. **BUSH, S. F.** Asymmetry and relative growth of parts in the two sexes of the hermit-crab, Eupagurus prideauxi. *Zeitschr. Wiss. Biol. Abt. D, Wilhelm Roux' Arch. Entwicklungsmech. Organ.* 123(1): 39-79. 16 fig. 1930.—After developing a method on 15, 64 ♀ and 56 ♂ hermit crabs were measured (64 measurements each; thoracic length and width, antenna 1-2, maxillipedes 3, pereiopods 1-5, uropods) and grouped by thoracic length to study asymmetry of the body, its changes during life, and the distribution of the "growth-potential" along the body. The greatest growth in the appendages occurred in the 3rd pereiopod; this grew more rapidly than the body, those in front and behind more slowly. The growth-gradient was the same for both sexes except that the relative speed of growth was less in most appendages in the ♀♀ than in the ♂♂ and that in both sexes (much more pronounced in the ♂♂) the regularity of the curve was interrupted by the very pronounced heterogony of the right chela, which showed a 2nd growth center. All appendages with the exception of the abdominal and of the last thoracic were larger on the right in both sexes than on the left. Graphically there was a right predominance, more abrupt in the ♂♂, which had its apex in the chela; in the ♂♂ the right predominance increased with the absolute size. The ♀♀ in all regions showed less right predominance, or more pronounced left predominance than the ♂♂. The change from the right to the left predominance in the ♀♀ occurred about a ½ segment farther forward than in the ♂. Graphic comparison of the ♂ to the ♀ appendages yields a gradient of ♂ predominance. This is negative for the eyestalk, the 5th pereiopod, and the abdominal appendages. In form it about agrees with the general growth gradient with the center at the 3rd pereiopod, but its regularity is interrupted on the right side by the heterogony of the right chela. The ♂ predominance in the head and thorax is greater on the right than on the left side. Every pereiopod shows a growth gradient with a center in the merus. The ♂ right chela begins its growth with a mode of the general pereiopod type, but of a definite size; in agreement with an increasing relative speed of growth of the entire limb the growth center shifts to the propus. This appears to be the unalterable site of the growth center in pronounced heterogonic crustacean limbs. The ♀ right chela showed a much less positive heterogony related to less increase in the speed of growth in the center of the propus. Regenerating chelae first show juvenile proportions, the adult proportions being restored by a rapid differential growth of the various segments.

8605. **CANNON, H. GRAHAM.** On the blood system of Parabathynella malaya, G. O. Sars. *Ann. and Mag. Nat. Hist.* 8(43): 109-114. 1 pl. 1931.—The chief interest in the blood system* lies in the occurrence of the first dorsal longitudinal muscles in the cavity of the vena dorsalis*. Contraction of these muscles must serve to dilate the cavity of this vessel. A rhythmical contraction of the series passing forwards would thus produce, in effect, a peristaltic wave which would suck in blood through the ostia and pass it forward to the heart.

8606. **[CHERNYSHEV, B. I.]** ЧЕРНЫШЕВ, Б. И. Новые Eryonidae с р. Вилюя. (New Eryonidae from Vilui River.) [English summary.] Известия Главного Геолого-Разведочного Управления. (*Bull. Geol. & Prospecting Service, USSR.*) 49(3): 103-111. 1 pl. 1930. —*Coleia* **sibirica*** (p. 106) and *Proeryon* **viluensis*** (p. 107), described from beds formerly considered Upper Jurassic, show them to be Liassic in age.

8607. **CHOPRA, B. N.** Pearl-like object found in a prawn. *Nature* [*London*] 126(3179): 502-503. 1 fig. 1930. —Description of a "pearl" from the abdominal region of a prawn (small peneid), apparently made of chitin.

8608. **COLOSI, G.** Lofogastridi nuovi. *Boll. Zool. Unione Zool. Italiana* 1(4): 119-125. 4 fig. 1930.—*Lophogaster* **erythraeus*** ♂ (p. 119), *L.* **affinis*** (p. 120), *Paralophogaster* **sanzoi*** ♂ (p. 122) and *P.* **microps*** (p. 123), all from the Red Sea.

8609. **CREASER, E. P.** The North American phyllopods of the genus Streptocephalus. *Occ. Papers Mus. Zool. Univ. Michigan* 217. 1-10. 2 pl. 1930.—A key, descriptions, synonymy and distribution of the 3 N. Amer. species (*Streptocephalus scalii, S. similis, S. texanus*) are given.—*E. P. Creaser.*

8610. **CREASER, E. P.** The Michigan decapod crustaceans. *Papers Michigan Acad. Sci., Arts & Lett.* 13: 257-276. 6 maps, 10 fig. 1931.—An illustrated key is given of the Michigan species of the genus *Cambarus*. *Palaemonetes exilipes** Stimpson is described. Ecological observations and distributional maps or lists are presented for all the Michigan decapods.—*E. P. Creaser.*

8611. **GRAF, HERBERT.** Der Fangapparat von Bosmina. *Zeitschr. Wiss. Biol. Abt. A, Morph. u. Ökol. Tiere* 19(2/3): 381-396. 17 fig. 1930.—In *Bosmina*, which, like Daphnidae and Chydoridae, is unable to select its food, the thoracic legs act together as a closed pumping system producing suction and pressure. They form a food catching device equipped with filters to concentrate the material suspended in the water. The filtering areas are composed of setae. In the mechanism are a pump, filters, excurrent water channels, and devices for the transport of the filtration residue to the mouthparts. —*H. Graf* (*transl. by C. H. Blake*).

8612. **HELDT, H., et Mme. H. HELDT.** Des langoustines (Nephrops norvegicus Leach) dans les mers tunisiennes. *Stat. Océanogr. Salammbô, Notes* 16. p. 5-16. 2 pl. 1931.—*N. norvegicus** is recorded as new to the fauna of Tunisia. Its distribution in the N. Atlantic and

in the Mediterranean is reviewed. Its general habitat is muddy bottoms at depths of 30-800 or more m.; off Tunisia, at 100-150 m. In Tunisia ♂♂ average longer (130 mm.) than ♀♀ (115 mm.); egg-bearing ♀♀ are found in December. The authors suggest that trawling at greater depths and at night off Tunisia would result in larger catches.

8613. **KIEFER, FRIEDRICH.** Die Untergattung Tropocyclops der Gattung Eucyclops (Copepoda, Cyclopoida). *Zeitschr. Wiss. Zool.* 138(3): 487-514. 8 fig. 1931.—Key is given to spp. and forms of *Tropocyclops; E.* (*T.*) *prasinus* f. guwana* (p. 507), Java; *E. p.* ssp. jerseyensis, New Jersey, *E. p.* ssp. meridionalis, Uruguay, *E.* (*T.*) extensus* and *E. e.* f. longispina*, New Jersey, (all p. 508); *E.* (*T.*) *confinis** f. frequens (p. 509), Pondoland, S. Africa; *E.* (*T.*) parvus (p. 509), Guatemala.

8614. **KLIE, WALTER.** Ostracoden aus dem paraguayischen Teile des Gran-Chaco. *Arch. Hydrobiol.* 22 (2): 221-258. 40 fig. 1930.—Ostracoda were collected by G. S. Carter in the neighborhood of 2 mission stations in Paraguay: Makthlawaiya (58° 19′ W., 23° 25′ S.), and Nanahua (59° 30′ W., 23° 30′ S.). Investigations were also made of the great shallow swamps, partially dried up, though not entirely dry, and on the small uniformly drying up water holes. Only 1 species of Cytheridae and 10 spp. of Cypridae were found, including: *Physocypria* longiseta* (p. 222), *Heterocypris* reticulatus* (p. 228), *H.* hyalinus* (p. 230), *H.* affinis* (p. 233), *Chlamydotheca* calcarata* (p. 236), *Strandesia* carteri* (p. 240).—*W. Klie* (*transl. by W. L. Tressler*).

8615. **LOWNDES, A. G.** Living ostracods in the rectum of a frog. *Nature* [*London*] 126(3190): 958. 1930.—The species was *Pionocypris vidua* O. F. Müller, which was living in the same aquarium as the frog.

8616. **LOWNDES, A. G.** Some rare and little-known British fresh-water ostracods. *Rept. Marlborough College Nat. Hist. Soc.* 79. 82-112. 8 pl. 1930(1931).—A systematic account of 7 spp., with synonymies, detailed descriptions, taxonomic remarks, distributional records, and figures. *Herpetocypris brevicaudata**, new to England and Brit. Isles.

8617. **MANTON, SIDNIE M.** Notes on the segmental excretory organs of Crustacea. V. On the maxillary glands of the Syncarida. *Proc. Linnean Soc. London* 142. 52. 1929/30(1931).—Abstract.

8618. **MONTGOMERY, S. K.** Report on the Crustacea Brachyura of the Percy Sladen Trust Expedition to the Abrolhos Islands under the leadership of Professor W. J. Dakin, D.Sc., F.L.S. in 1913; along with other crabs from Western Australia. *Proc. Linnean Soc. London* 142. 14-15. 1929/30(1931).—Abstract.

8619. **NICHOLLS, G. E.** A new syncaridan from the west coast of Tasmania. *Proc. Linnean Soc. London* 142. 6-7. 1929/30(1931).—Described but not named.

8621. **RIESTER, ALBERT.** Muskulatur von Copilia Dana, mit einem Anhang über die Mundteile, die Ernährung und die Lebensweise. *Zool. Jahrb. Abt. Anat. u. Ontog. Tiere* 53(2): 317-404. 52 fig. 1931.—The whole muscular system of a copepod (*Copilia mirabilis*) is described with regard to the functional importance of each group of muscles, including: (1) the muscles of the body, of which the ventral longitudinal muscles and the muscles of the furcal rami, showing a number of complicated sinews, are of special interest; (2) the locomotory muscles of the appendages; (3) the muscles of the joints of the legs; (4) the muscles and sinews of the inner organs, especially those of the pharynx and esophagus of the ♂♂ as well as those of the genital opening of the ♀♀. The supplement treats particularly of the mouth parts of the ♂♂ and ♀♀ of the genus *Copilia;* those of the ♂♂ can easily be identified. A comparison is made with the locomotion of *Cyclops.—A. Riester.*

8622. **SCHIKLEJEW, S. M.** Einige interessante Arten der Eucopepoda aus den Gewässern des Talgebietes Manytsch (Nordkaukasus). *Zool. Anz.* 95(5/8): 142-148. 6 fig. 1931.—*Diaptomus bacillifer**, redescription; *Wolterstorffia blanchardi*, descriptive notes.

8623. **SCHMITT, WALDO L.** Trawling for crustaceans at Tortugas, Florida. *Smithsonian Inst., Explorations and Field-Work of the Smithsonian Inst. in 1930. Publ.* 3111. 103-106. 2 pl. 1931.—Includes notes on the rare *Bathynomus* and *Benthochascon.*

8624. **SHEN, CHIA-JUI.** The crabs of Hong Kong. Part I. *Hong Kong Naturalist* 2(2): 92-110. 7 pl., 11 fig. 1931.—A systematic account of 11 local spp., including synonymies, descriptions, habitat notes, statements of distribution, and figures.

8625. **SHERRARD, KATHLEEN.** Notes on a phyllocarid and a brachiopod found in the Lancefield zone of the Lower Ordovician rocks of Victoria. *Proc. Roy. Soc. Victoria* 42(2): 135-139. 1 pl. 1930.—Crustacea: *Hymenocaris* ornata* (p. 136). Brachiopoda: *? Siphonotreta* lancefieldensis* (p. 137). Types in Univ. of Melbourne.

8626. **SMIRNOV, S.** Zur Systematik von Diaptomus fischeri Rylov und Diaptomus acutulus Brian (Crustacea, Copepoda). Доклады Академии Наук СССР., Сер. А. (*Compt. Rend. Acad. Sci. URSS., Sér. A*) 1930(3): 55-60. 5 fig. 1930.—Emended descriptions, including first description of ♀ of *D. fischeri**.

8627. **SMIRNOV, SERGIUS.** Zur Synonymik von Eurytemora adleri Schiklejew. *Zool. Anz.* 95(11/12): 277-278. 1 fig. 1931.—*Eurytemora velox** Lillj. (=*E. adleri* Schikl.).

8628. **[SMIRNOV, S. S.]** СМИРНОВ, С. С. О двух новых формах Copepoda из Амурского края. [Two new forms of Copepoda from the Amur region.] Доклады Академии Наук СССР., Сер. А. (*Compt. Rend. Acad. Sci. URSS., Sér. A*) 1930(11): 281-286. 1 fig. 1930.—Descriptions are in both German and Russian. *Attheyella* borutzkyi* (p. 281); *Cyclops languidoides* v. gracilicaudatus* (p. 285).

8629. **STÅLBERG, GEORGES.** Eine Calanus-Form aus dem Telezker See im Altai. *Zool. Anz.* 95(9/10): 209-220. 13 fig. 1931.—*Calanus finmarchicus* v. telezkensis* (p. 218), Tomsk, Siberia.

8630. **TEISSIER, GEORGES.** Sur la faune des stations abritées, un facteur possible de la répartition des espèces sessiles. *Trav. Stat. Biol. Roscoff* 8. 187-189. 1930.—In the fish pond of the Roscoff Biol. Station are living *Balanus perforatus* and *B. crenatus* which ordinarily occur in very dense populations, while here they are not numerous, very scattered, and attain large size. The author reflects on the factors of stillness and agitation of waters, the difficulties experienced by the larvae in fixing themselves, and that the absence of a certain spp. from a certain place does not indicate that it cannot live there, but that perhaps it has not been able to get there.

8631. **WEISIG, STEPHAN.** Diaptomus atropatenus sp. nov. Mit einem Beitrag über die Diaptomidenfauna des östlichen Transkaukasiens. *Zool. Anz.* 95(9/10): 255-262. 2 fig. 1931.—*Diaptomus* atropatenus* (p. 255), Transcaucasia; notes are given on other spp. of *Diaptomus.*

ENTOMOLOGY

GENERAL

ROYAL N. CHAPMAN, *Editor*

(See also in this issue Entries (Technique) 6110, 6111, 6112; (Genetics) 6162, 6179, 6195, 6202, 6205, 6210, 6211; (Ecology) 6258, 6260, 6314, 6317, 6321, 6326, 6327; (Development) 6306; (Pollinators) 6260, 6261; (Plant disease vectors) 6359, 6363, 6368, 6369, 6370, 6371, 6372, 6377, 6398, 6413, 6414, 6417; (Growth) 6812, 6899; (Digestion) 6984; (Respiration) 7005; (Animal disease vectors) 7233, 7531, 7533, 7556, 7586, 7640, 7687, 7970; (Parasites) 7503, 7527, 7558, 8497; (Immunity) 7502; (Control) 7970, 7994; (Histology) 8429, 8431; (Distribution) 9051, 9056, 9057, 9061)

8632. **BEQUAERT, J. Medical and economic entomology.** In: **The African Republic of Liberia and the Belgian Congo, based on the observations made and material collected during the Harvard African Expedition 1926-27.** Vol. 2. (*Contr. Dept. Trop. Med. & Inst. Trop. Biol. & Med.* no. 5) Part 3. XXXVI: Entomology. p. 797-1001. Map, 4 pl., 8 fig. Harvard Univ. Press: Cambridge, 1930.—This report on part of the Arthropoda collected covers the following orders: Linguatulida, Ricinulei, Acarina, Isoptera, Heteroptera, Dermaptera, Orthoptera, Diptera, Anoplura, Mallophaga, Siphonaptera, and Coleoptera. The systematic list of spp. includes synonymy, distribution, taxonomic remarks, and notes on habits and medical or economic significance, with numerous records of the hosts of parasitic spp. A number of unidentified Linguatulidae are recorded from known hosts. The genus *Ixodes* [Ixodidae] is recorded as new to Liberia. Fifteen spp. of Culicidae are recorded as new to Liberia. The treatment of Tabanidae is not restricted to the material of the Harvard African Expedition, but includes a synopsis of all spp. known from the Belgian Congo and critical remarks on classification of genera and subgenera, with a key to the genera found in the Ethiopian region. In contrast to Enderlein's 9 subfamilies, the author recognizes only 3 subfamilies.

8633. **COOK, WILLIAM C. Some influences of location upon light trap catches.** *Canadian Ent.* 62(5): 95-98. 1930.—Comparison of catches of 2 similar light traps, one in a field, the other in a 3rd-story window.

8634. **CRAMPTON, G. C. The basal structures of the wings of certain insects.** *Bull. Brooklyn Ent. Soc.* 23(3): 113-118. 1 pl. 1928.—The author points out that in certain "neopterygotan" insects, as well as in others, there occurs a basal wing fold with a corresponding pocket, apparently developed in connection with their ability to hold the wings along the top of the abdomen in repose. The alar ossicles and the notal structures connected with the articulation of the wings are also described.—*R. B. Friend.*

8635. **ECKSTEIN, KARL. Bilder aus dem Insektenleben.** 140p. Ullstein: Berlin, 1927. Pr. 85M.—A popular handbook on the habits and life-histories of German insects. The first chapter deals with insect structure. Other chapters discuss the habits and life-histories of common Coleoptera, Lepidoptera, Diptera, and Vespoidea, predators, parasites, gall insects, sap-suckers, and leaf-miners. The two final chapters treat of reproduction, development, and the factors affecting the life cycle. —*E. M. Du Porte.*

8636. **ELTRINGHAM, H. Histological and illustrative methods for entomologists. With a chapter on mounting whole insects, by H. BRITTEN.** pp. xi+139. 1 pl., 18 fig. Oxford Univ. Press: New York, 1930. Pr. $2.50.—Following an introduction, the chapters deal with apparatus, reagents, and materials; preparation of wing neurations, scales, etc.; genitalia preparation; fixing, embedding, and section-cutting; staining and other processes; making preparations of small whole insects; making drawings; coloring lantern slides and photographs; and making models.

8637. **FROST, S. W. A suggestion for relaxing small insects.** *Ent. News* 41(5): 152-153. 6 fig. 1930.—The making of small paper boxes to be placed in a single relaxing jar, as a means of keeping the records separate, is described in detail.

8638. **GRUHL, KURT. Neue Beiträge zum Problem der Lufttänze.** *Zeitschr. Ent.* 15(3): 1-13. 1927.—A discussion of the dances of Diptera as compared with those of Ephemerida, Trichoptera, and Lepidoptera.

8639. **HAYWARD, KENNETH J. Sobre migración de insectos, con referencia especial a la Argentina.** *Rev. Soc. Ent. Argentina* 2(5): 209-216. 1929.—The author suggests a standardized set of data to be noted, when possible, by observers of insect migration.

8640. **HEIKERTINGER, F. Einige ergänzende Bemerkungen zu F. Rüschkamps Worten über Präparation, Bezettelung und Kartei im Dienste der Insektenkunde. [Remarks on F. Rüschkamp's notes on preparation, labeling, and arranging in entomology.]** *Koleopterol. Rundsch.* 16(5): 167-171. 1930. [See also in this issue entry 8650.]

8641. **IMMS, A. D. Some methods of technique applicable to entomology.** *Bull. Ent. Res.* [*London*] 20(2): 165-171. 1929.—Various methods of technique used by the writer over a number of years are described, many of them not generally known. The majority are simple and easily used. Various mounting media, methods of staining chitin, dissecting and preserving fluids, and methods of rearing insects are described.—*A. D. Imms.*

8642. **LE CERF, FD. Une technique simplifiée pour la coloration des genitalia.** *Encyclop. Ent. Ser. B, Lepidoptera* 3(4): 147-152. 1929.—After many experiments the writer has settled on the following formula for staining insect genitalia: After passing through potash solution, place in ordinary copying ink, to which has been added 1/10 by volume of acetic acid crystals. Leave in this for from 5 to 20 minutes. Remove and place in water acetified to 1/10 at least, and agitate until the desired color is obtained. Remove and wash in 90% alcohol for 5 to 15 min. Mount directly in mastic resin dissolved in 90% alcohol. In an addenda the writer gives a modification of this formula for treating eggs to permit study of the minute structures. After the acetified water solution, place the eggs in an aqueous solution of eosine for 5 to 60 minutes. Mount directly in gum arabic of syrupy consistency in water. The slow evaporation permits the study under the microscope of the fine structures of the egg.

8644. **MARSHALL, JOHN F. A new form of apparatus for photographing insects.** *Bull. Ent. Res.* [*London*] 21(2): 139-140. 2 pl. 1930.—A modification of the apparatus earlier described by the author (Bull. Ent. Res. 15: 49.), with a greater focal length (hence better for photographing larger insects [than mosquitoes]) and with "distant control" devices to enable the operator to observe the image on the focussing screen while altering its size, focus, position, and illumination.

8645. **MICKEL, CLARENCE E. Descriptions plus types vs. descriptions alone.** *Psyche* 37(2): 118-131. 1930.—Discussions of Embrik Strand's views on type specimens, in cases of descriptions of new species.

8646. **NAVÁS, LONGINOS. Excursiones por la provincia de Gerona en Julio y Agosto de 1928.** *Butl. Inst. Catalana Hist. Nat.* 9(1/2): 27-48. 5 fig. 1929.—A list, with locality data, of 263 spp. of insects of various orders, which were collected in northeastern Spain.

8647. **REMY, PAUL. Quelques Arthropodes récoltés**

dans la region du Scoresbysund (Groenland oriental) au cours de la croisière arctique du "Pourquoi-Pas?" en 1926. *Meddel. om Grönland* 74(7): 83-95. 1 fig. 1928.—An annotated list of 7 Acarina; *Pediculus humanus* v. *capitis* de Geer from Eskimos; Hymenoptera (*Stenomacrus laticollis* Holmgr. and 2 spp. of *Bombus*); 7 spp. of Chironomidae; *Aedes alpinus* L.; *Tipula arctica* Curtis; 4 spp. of Brachycera; 5 spp. of Lepidoptera.

8648. **ROCCI, UBALDO.** Appunti polemici. *Boll. Soc. Ent. Ital.* 62(9): 163-172. 1930.—Includes a criticism of the rule proposed by the British National Committee on Entomological Nomenclature that the same subspecific or varietal name should not be used twice in the same genus. The author believes changes in nomenclature made on this basis are unfair to the original authors.

8649. **RÜSCHKAMP, F.** Arbeitsgemeinschaft Rhein. Coleopterologen. *Ent. Blätter* 25(1): 59-62. 1 pl.; (4): 204-205. 1929; 26(1): 42-43; (3): 138-141. 1930.—6th and 7th meetings at Bonn, Sept. 1928 and Jan. 1929 with group photograph and note on phylogeny and ecology of Histeridae by REICHENSPERGER. 8th meeting at Hinsbeck a. Niederrhein, May 1929 with list of 22 spp. collected. 9th meeting at Bonn, Sept. 1929, with list of 24 spp. collected. 10th meeting at Köln, Jan. 1930. 11th meeting at Kreuzberg, June 1930, with list of about 75 spp. collected.—*M. H. Hatch.*

8650. **RÜSCHKAMP, F.** Aus der Praxis des Käfersammlers XV. Einige Worte über Präparation, Bezettelung und Kartei im Dienste der Insektenkunde. [Methods of collecting Coleoptera XV. Preparation, labeling, and arranging.] *Koleopterol. Rundsch.* 16(5): 165-167. 1930.

8651. **SAZ, EUGENIO.** Costumbres de insectos observados en plena naturaleza. [Insect customs observed in nature.] Vol. 1. 104p. Vol. 2. 96p. Revista Iberica: Barcelona, 1930. Price: 2 pesetas each vol.

8652. **SHAFIK, M., and A. B. P. PAGE.** Control of mites attacking stocks of insects and fungous cultures. *Nature* [*London*] 126(3174): 311-312. 1930.—Pyridine and ammonia, recommended by Jewson and Tattersfield (Ann. Appl. Biol. 9: 213. 1922) for removal of mites from fungous cultures, were found to be harmful to insects and to their food. Cultures of various fungi were freed of mites by exposure to CCl_4 (0.5 cc. per liter) for 24 hrs. Fumigation of infested stocks of *Calandra granaria* in barley and maize, and of stocks of *Rhizopertha dominica* in maize, with CCl_4 at a concentration of 0.5 cc./litre for 4 hrs. killed the mites while, after thorough aeration, the bulk of the adult insects recovered. Trichlorethylene was effective at half that concentration in 24 hrs., but was more destructive to the insect cultures.

8653. **STEP, EDWARD.** British insect life: a popular introduction to entomology. Rev. ed. 264p. 40 pl. T. Werner Laurie, Ltd.: London, 1929. Pr. 25s.

8654. **TAKAHASHI, RYOICHI.** A general consideration on the insects of Jitsugetsutan (Lake Candidius.) [In Japanese.] *Trans. Nat. Hist. Soc. Formosa* 20(108): 145-156. 1930.—Annotated list.

8655. **TAVARES, J. S.** Cecídias de Zumárraga (Guipúzcoa, Espanha). *Brotéria, Ser. Zool.* 26(3): 113-119. 1930.—A list of 40 insect galls on 15 host plants, including galls of Aphididae, Rhynchophora, Acarina, Thysanoptera, Cynipidae, and Cecidomyidae. Descriptive notes are presented on the galls of *Aphis piri* on *Crataegus monogyna, Mikiola fagi* on *Fagus silvatica, Thrips* sp. on *Linum* sp. [a new gall], *Siphocoryne xylostei* on *Lonicera periclymenum, Perrisia populeti* on *Populus tremula, Eriophydarum* sp. on *Pteris aquilina, Diplolepis longiventris* and *Neuroterus numismalis* on *Quercus pedunculata,* and *Lasioptera rubi* on *Rubus* sp.

8656. **TORRE-BUENO, J. R. de la.** The type fetish. *Psyche* 37(1): 80-82. 1930.—A discussion of Embrik Strand's views on type specimens.

8657. **THORPE, W. H.** Biological races in insects and allied groups. *Biol. Rev. & Biol. Proc. Cambridge Philos. Soc.* 5 (3): 176-212. 1930.—A critical summary of recent literature, with an extensive bibliography.

8658. **VITZTHUM, H.** Die Präparation kleiner landbewohnender Arthropoden. *Mikrokosmos* [*Stuttgart*] 24 (2): 34-37. 1930/31(1930).

8659. **VOS, A. P. C. de.** Über die Verbreitung der aquatilen Insektenlarven in den Niederlanden. *Internat. Rev. Ges. Hydrobiol. u. Hydrograph.* 24(5/6): 485-506. 8 fig. 1930.—A list of aquatic insect-larvae found previously in the Netherlands: Ephemerida (23 spp.), Odonata (30 spp.), Plecoptera (3 spp.), Neuroptera (2 spp.), Trichoptera (77 spp.), and Lepidoptera (1 sp.); 3 aberrant forms (*Heptagenia* sp., *Agrion* sp. and *Hydropsyche* sp.), described and figured. Distributions within the country are indicated and short résumés given on the ecology of the most important spp.—*A. P. C. de Vos.*

8660. **WEBER, HERMANN.** Das Problem der Gliederung des Insektenthorax. Eine Antwort auf H. J. Feuerborns Beiträge zu diesem Thema. I., II. und III. Mitteilung. *Zool. Anz.* 65(9/10): 233-248. 2 fig.; 66 (1/4): 9-31. 4 fig.; (5/6): 115-132. 2 fig. 1926.

8661. **WISHART, GEORGE.** Some devices for handling insects. *Jour. Econ. Ent.* 23(1): 234-237. 4 fig. 1930. —The following are described: a catcher for small Hymenoptera and Diptera with the breath as power; a small catcher for Lepidoptera with the breath, with a filter to prevent the scales from entering the throat of the operator; a small catcher for Lepidoptera with atomizer bulbs; a device for use in catching and sorting large numbers of insects, with a vacuum sweeper as power.—*G. Wishart.*

ARACHNIDA (EXCEPT ACARINA)

ALEXANDER PETRUNKEVITCH, *Editor*

(See also in this issue Entries 7799, 7821, 8632, 8914, 9056, 9061)

8662. **BIRULA, A.** Über Galeodes armeniacus n. sp. *Zool. Anz.* 84(11/12): 273-282. 7 fig. 1929.—*G. armeniacus** (p. 273), Armenia, is about the same size and occurs along with *G. araneoides* Pallas, but differs from the latter in shape and coloring. The fact that the marginal spines on the last segment of the 4th pair of legs are wanting, establishes the affinity, as well as the taxonomic position, of the new species with *G. araneoides* and *G. arabs.* Up to the present *G. armeniacus* has been found in the Araxes valley only, whereas *G. araneoides* occurs not only in the valley itself but also high up in the mountains.—*H. Wiehle.*

8663. **BORELLI, ALFREDO.** Scorpioni nuovi o poco noti della Somalia Italiana. [New or little known scorpions from Italian Somaliland.] *Ann. Mus. Civ. Storia Nat. Genova* 52: 9-16. 1925/1928.—*Buthus* insolitus (p. 9) and *Parabuthus* mixtus (p. 13); types in Mus. Civ. Storia Nat. Genova. Seven other spp. are listed.

8664. **BORELLI, ALFREDO.** Risultati zoologici della Missione inviata dalla R. Società Geografica Italiana per l'esplorazione dell' oasi di Giarabub (1926-1927). Scorpioni e solifughi. [Zoological results of the Mission sent by the Ital. R. Geogr. Soc. for exploring the Oasis of Jarabub (1926-1927). Scorpiones and Solifugae.] *Ann. Mus. Civ. Storia Nat. Genova* 52: 346-355. 1925/1928.—

A record of 11 Scorpiones and 1 Solifugae, with notes on each: *Buthus amoreuxi* v. *deserticola*, extended description of ♂ and ♀.

8665. **BRISTOWE, W. S.** A contribution to the knowledge of the spiders of South Wales. *Ann. and Mag. Nat. Hist.* 8(44): 173-177. 1931.—An annotated list.

8666. **BRISTOWE, W. S.** A contribution to the knowledge of Scottish spiders—Kirkcudbrightshire. *Scottish Nat.* 1931(191): 153-155. 1931.—A list of 84 Araneae and 4 Phalangidea.

8667. **BROILI, FERDINAND.** Über ein neues Exemplar von Palaeopantopus. *Sitzungsber. Math.-Naturwiss. Abt. Bayerischen Akad. Wiss.* 1930(3): 209-214. 1 fig. 1930.—Pycnogonida (Pantopoda): **PALEOPANTOPODA** (p. 209), a new [ordinal?] group erected for the Lr. Devonian *Palaeopantopus maucheri**.

8668. **[ERMOLAEV, V.]** ЕРМОЛАЕВ, В. К вопросу о распространении в Сибири тарантула Hogna (Trochosa) singoriensis (Laxm.). [Distribution of H. singoriensis in Siberia.] Русское Энтомологическое Обозрение. (*Rev. Russe d'Ent.*) 24(3/4): 212-217. Map. 1930.—Previous records are reviewed and a distributional map, based on old and new records, is presented.

8669. **GRAVIER, CH.** L'appendice caudal des limules. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1(1): 94-99. 2 fig. 1929.—A detailed description is given of the caudal appendage* of *Tachypleus tridentatus*. The structure of this appendage is the basis of a key differentiating *T. gigas**, *T. tridentatus*, *Xiphosura polyphemus*, and *Carinoscorpius rotundicauda*.

8670. **GUDGER, E. W.** More spider hunters. Accounts of arachnids which attack and devour vertebrates other than fishes. *Sci. Monthly* 32: 422-433. 9 fig. 1931.—Continuing previous articles on such habits of certain large and voracious spiders, some 20 accounts are given of spiders catching and eating amphibians, reptiles, birds, and mammals. In their work on spider poisons at Butantan, Brazil, Vital Brazil and J. Vellard state that they habitually feed their spiders on frogs, lizards, and snakes. Data set out in this and in previous papers, show that spiders, commonly supposed to feed on insects only, also catch and eat vertebrates of all phyla from fishes to mammals.—*E. W. Gudger.*

8671. **GUDGER, E. W.** Some more spider fishermen. *Nat. Hist.* [*New York*] 31(1): 58-61, 3 fig. 1931.—Three well attested cases (one directly from the observer) and 2 unverified ones are added to the 9 previously compiled of spiders catching fishes, definitely establishing the fact that certain large spiders catch and eat small fishes.—*E. W. Gudger.*

8672. **HADŽI, JOVAN.** Die europäischen Skorpione des Polnischen Zoologischen Staatsmuseums in Warszawa. *Ann. Mus. Zool. Polonici* [*Warsaw*] 9(4): 29-38. 4 fig. 1930.—Descriptive notes on *Euscorpius italicus mesotrichus*, *E. carpathicus polytrichus**, *E. c. mesotrichus**, *E. c. oligotrichus**, and *E. germanus mesotrichus*, with tables of comparative measurements of numerous specimens.

8673. **HADŽI, JOVAN.** Contribution à la connaissance des Pseudoscorpions cavernicoles (Chthonius spelaeophilus sp. n.; Chth. raridentatus sp. n.; Chth. cavernarum Elling.) [Text Serbo-Kroatisch; summary in French.] *Glas Srpske Kraljevske Akademije* 140: 113-148. 13 fig. 1930.—True cave inhabiting pseudoscorpions are derived from several groups; for example in the genus *Obisium* there occurs the cave inhabiting subgenus *Blothrus*, and in *Roncus* the cavernicolous subg. *Parablothrus*. In some other groups (*Chelifer*, *Chernes*) no extreme cave types have developed but there may be observed in them nevertheless the presence of single "cave characteristics," developed independent of the cave, which, in case of a change to cave life, would lead to the typical extreme developments. Some true cave types occur also in the genus *Chthonius*. From several caves in the western part of Karst (Carso) (now part of Jugoslavia) have come the 3 spp. noted in the title. Examples are given, described, and illustrated. Both new species are true, blind cave forms. *Chthonius* **spelaeophilus*** (p. 118) stands next to *cephalotes* Simon and of the Jugoslavian species to *dalmatinus* Hadži (previously *C. rayi dalmatinus* Hadži). *C. cavernarum* Ellingsen, which also lives outside of caves and occurs in countries neighboring to Jugoslavia, was re-diagnosed. Contrary to Beier's opinion, *C. troglodytes* Redikorzev came from a Bulgarian cave and *C. heterodactylus* Tömösváry is not identical with *C. cavernarum*. *C.* **raridentatus*** (p. 133) and other species possessing heterodactylous, sigmoidal pedipalpal chela fingers are thrown together in a new subgenus **SIGMODACTYLUS*** (p. 140). Types of new species, mounted in Canada balsam, are in Zool. Inst., King Alexander's Univ., Ljubljana, Jugoslavia.—*J. Hadži* (*transl. by J. C. Chamberlin*).

8674. **KÄSTNER, ALFRED.** Biologische Beobachtungen an Phalangiiden. *Zool. Anz.* 95(11/12): 293-302. 10 fig. 1931.—The possible functions of the long legs of the Phalangiidae, as illustrated by *Liobunum rotundum**, are discussed and the manner of grasping with the tarsus illustrated. A number of sketches illustrate the flexible structure of the articulation of the tarsi. In opposition to the old opinion that phalangiids are night animals, records of observations of several species active in the daytime are quoted. They are insectivorous.

8675. **LOMAN, J. C. C.** Addendum à la liste des Pycnogonides récoltés sur la côte Atlantique du Maroc par le Dr. J. Liouville et R. Ph. Dollfus. *Bull. Soc. Sci. Nat. Maroc* 9(1/6): 71. 1929.—Records of 4 spp., one of which is a *Leonymphon*. This genus has previously been known only from arctic regions.

8676. **MELLO-LEITÃO.** Nota sobre Arachnideos Argentinos. *Ann. Acad. Brasil. Sci.* 2(4): 211-214. 1930.—Gonyleptidae: **APEMBOLEPHENINAE** (p. 212), new subf., based on *Apembolephaenus* and *Proampycus*; *Discocyrtus* **argentinus** ♂ (p. 212), type in Mus. de Buenos Aires; *Pucrolia* **grandis** ♀ (p. 213), type in Mus. Bernardino Rivadavia; **MICROGONIOSOMA** (p. 214) (Gonyleptinae), based on *M.* **fuscum** ♂ (p. 214), type in Mus. Bern. Rivad.

8677. **MEYERS, J. G.** Ethological notes on some New Zealand land spiders. 2. *New Zealand Jour. Sci. and Technol.* 9(3): 129-139. 1927.

8678. **NAKAJIMA, T.** (transl. by Ling Ping Huang). A list of spiders of Fukien Province, China. *Nat. Hist. Soc. Fukien Christian Univ. Foochow, China* 2: 17-20. 1929.—One hundred and two spp. are listed.

8679. **PALLARY, PAUL.** Description de quatre scorpions nouveaux de la Berbérie. *Bull. Mus. Nation. Hist. Nat. Paris* 1928(5): 346-351. 1 pl. 1928.—*Heterometrus* **fuliginosus*** (p. 346). *Prionurus* **eburneus*** (p. 348), *Buthacus* **exilis*** (p. 349), and *Prionurus* (?) **tingitanus*** (p. 350). Types in Mus. Nation. Hist. Nat., Paris.

8680. **ROEWER, C. FR.** Drei neue Cosmetiden (Opilioniden) aus Mexiko. *Zool. Anz.* 95(9/10): 247-250. 3 fig. 1931.—*Cynorta* **skwarrae*** (p. 247), on *Aechmea bracteata*; *C.* **dampfi*** (p. 248), on *Aechmea mexicana*; *Cynortula* **wheeleri*** (p. 249), on *Aechmea mexicana* and *A. bracteata*, also on stem of banana and *Cocolapa*.

8681. **SCHENKEL, E.** Beitrag zur Spinnenkunde. *Zool. Anz.* 83(5/8): 137-143. 4 fig. 1929.—Following an examination of spiders from the Mecklenburg moors, the author describes the following species, the first 2 of which are cited as new but with an interrogation point: *Gonqylidiellum* **minutissimum*** (p. 138); *Centromerus* **pallidulus*** (p. 139); *Lephthyphantes* **rabeleri** (p. 140); *Gnaphosa leporina* (L. Koch) is reported as new to Germany. One adult ♀ *Tricca lutetiana* (Simon) examined differed, in the spines of the 2nd leg, from Dahl's description of this species.—*H. Wiehle.*

8682. **THOMAS, MAURICE.** L'instinct chez les araignées. XV, XVI, XVII, XVIII. *Bull. et Ann. Soc. Ent. Belgique* 70(6/8): 183-196. 1 fig.; (9): 229-249. 1930.—XV. Before mating the ♂ *Xysticus pini* Hahn surrounds the ♀ with several threads of silk in order to gain time for escape. Danger to the ♂ of being devoured after pairing is not general; not all the ♀♀ show the same

ferocity in this respect.—XVI. The nuptial dance. The mating of *Pardosa* (=*Lycosa*) *amentata* and *P. lugubris* proves that the nuptial movements are rigorously fixed for these spp. Among Attidae, the movements apparently merely express the excitement of the ♂. In the Lycosidae they aim to excite recognition by the ♀ and to charm her; for, in contrast to the Attidae, the Lycosidae ♀♀ take a great interest in the movements of their ♂♂ and seem to evince a certain emotion, which manifests itself in agitated trembling and in caresses of the dancing ♂♂ by means of the forelegs. The identity of movements within a sp. shows that instinct is, in a measure, independent of physiology and anatomy; for nothing, anatomically or physiologically, could possibly prevent the ♂♂ of one species from dancing or mating in the same fashion as a related species, which is not the case.—XVII. *Nephila madagascariensis*, unlike most European species, does not repair its web daily, but whenever it is damaged. Simple rents are repaired in the evening by means of irregularly fastened threads.—XVIII. *Arancus quadratus* Clerck, instincts. The hatch from 2 sacs of eggs consisted of 500-700 individuals. Rapidity of dispersal (1-8 days) depends on atmospheric conditions, being slow and in small groups if temp. is unfavorable, but rapid in good weather. It may begin several days to several weeks after hatching. The first webs are constructed without hesitation or experimentation. Instincts are not determined by somatic characters and environmental conditions. An instinct requires an appropriate mechanism, but the existing organ permits diverse uses among which the instinct chooses. Secretion of silk and presence of spinnerets are anatomical and physiological characters permitting manifestation of diverse instincts. But many hunting spiders secrete silk adequate in quality and sufficient in quantity to spin webs, yet the corresponding instinct is lacking. Moreover, the difference in the structure of webs does not find its explanation in physiological and anatomical differences; and again, spp. of very diverse habits inhabit the same environment. Instinct is therefore innate and not altered by the individuals. The orb-web is too complex to be invented by young spiderlings emerging from the egg; and even if they were to conceive a plan, not all would arrive at the same result. Instinct is therefore a real, innate heritable knowledge; it is a psychological character, not a physical or a chemical one. The fact that individuals of the same species, both in the New and Old World, have exactly the same habits, proves that instinct is throughout all time immutable.—*M. Thomas* (*transl. by R. A. Muttkowski*).

8683. THULIN, GUSTAV. Über die Phylogenie und das System der Tardigraden. *Hereditas* 11(2/3): 207-266. 28 fig. 1928.—A new classification is suggested for the Tardigrada. The 2 main groups (orders Heterotardigrada and Eutardigrada) proposed by Marcus are retained but are divided into families: **HALECHINISCIDAE** (p. 210), erected for *Halechiniscus, Batillipes, Bathyechiniscus,* and *Tetrakentron;* Echiniscidae, considered to include *Echiniscus, Echiniscoides, Parechiniscus, Pseudechiniscus,* and *Oreella;* Arctiscidae, considered to include only *Arctiscon;* and **MACROBIOTIDAE** (p. 228), erected for *Macrobiotus, Hypsibius,* and *Diphascon.* A general systematic review of the 2 major groups is given, together with a discussion of their phylogeny and relationships. Echiniscidae: **BRYODELPHAX** (p. 220), type *B.* **parvulus*** (p. 221), Canada, including also *B.* **intermedius** (*Echiniscus i.* Murray) (p. 221) and *B. i.* var. **hawaiicus** (p. 221), Hawaii; **HYPECHINISCUS** (p. 221), erected for *H.* **gladiator** (*Echiniscus g.* Murray) (p. 221). Macrobiotidae: **CALOHYPSIBIUS** (p. 238), type *C.* **ornatus** (*Macrobiotus o.* Richters) (p. 238), including also *C.* **verrucosus** (*Macrobiotus ornatus* var. *v.* Richters) (p. 239) and *C.* **scabrorus** (Murray), n. comb. (p. 239); **MICROHYPSIBIUS** (p. 239), erected for *M.* **truncatus*** (p. 247), Scotland; **ISOHYPSIBIUS** (p. 239), type *I.* **prosostomus** (p. 250) [Locality not stated], including also *I.* **undulatus*** (p. 249), *I.* **septentrionalis** (p. 250) and *I.* **granulifer*** (p. 251), Sweden, and *I.* **megalonyx** (p. 252) [Locality not stated]; *Hypsibius* **microps*** (p. 253), Sweden and Siberia; *Diphascon* **tenue*** (p. 255), Faeroe Isls.; *D.* **prorsirostre*** (p. 256), Sweden, Germany, and Scotland; *D.* **arduifrons*** (p. 257), Sweden and Siberia; *Macrobiotus* **luteus** (p. 257), Sweden; *M.* **spectabilis** (p. 259), Siberia.—*M. L. Hett.*

8684. VIRIEUX, A. Les araignées aéronautes. *Bull. Soc. Vaudoise Sci. Nat.* 57(223): 31-32. 1929.—The author briefly summarizes the work of his predecessors, claiming that the problem concerning ballooning of spiders is not yet solved. He analyzes the different phases of flight, maintaining that the spider accomplishes a voluntary act. To Blackwall's 4 species particularly adapted for flight, 2 are added from his own observation: *Lephthyphantes tenuis* and *Nematogmus sanguinolentus.*—*L. F. Pinkus.*

(=*C. strigosum* Sahlb.); *Agathidium mandibulare* Strm. (=*A. pallidum* Gyll.); *Athous zebei* ab. **nigrescens** (p. 77); *Corticaria crenicollis* Mann. (=*C. polypori* Sahlb.); *Cryptophagus bimaculatus* Panz. (=*C. villosulus* Sahlb.); *C.* **sahlbergi** (*C. amplicollis* Sahlb. preoc.) (p. 78); *C. setulosus* Strm. (=*C. crassicornis* Sahlb.).

8704. HEYROVSKÝ, LEO. Pozoruhodné nálezy broukû Československé Republiky. [Remarkable find of Czechoslovakian beetle.] *Časopis Československé Společnosti Ent.* [*Prague*] 26(1/2): 37-38. 1 fig. 1929.—*Judolia erratica* ab. **prokši** (p. 37), from Prague, is new. *Strangalia arcuata, Phymatodes fasciatus, P. glabratus,* and *Purpuricenus koehleri* v. *nigricollis* are new to Bohemia. *Exocentrus punctipennis,* known formerly only from southern Europe, Asia Minor, Switzerland, Prussia, and Silesia, was found in two cases near Prague. *Dryocoetus hectographus* was collected in Bohemia, Moravia, Slovakia, and Carpatho-Russia. *Crypturgus hispidulus* has been found with *Polygraphus grandiclava* in pine and fir woods at approximately 1000 m. altitude on the Radhost (Moravian Beskiden) and in the giant mts., *P. grandiclava* found previously only on cherry and *Pinus cembra.*—*German abstract (transl. by H. G. Good).*

8705. KÔNO, HIROMICHI. Langrüssler aus dem japanischen Reich. *Insecta Matsumurana* 4(4): 145-162. 1930.—Keys to the Japanese genera and spp. of the tribes Tychiini, Gymnetrini, Cionini, Nanophyini, Erirhini, and Smicronychini are given, with list of the spp. New forms are: *Tychius* **ginsuji** (p. 145), *T.* **iwatensis** (p. 146), *Miarus* **kobanzo** (p. 148), *Cionus* **tamazo** (p. 149), and *C.* (*Stereonychus*) **ogasawarai** (p. 150), all 5 Japan; *Nanophyes* **chibizo** (p. 152), *N.* **formosensis** (p. 153), and *N.* **miwai** (p. 154), Formosa; *N.* **usuironis** (p. 152), *Dorytomus* **rufus** (p. 155), and *D.* **notaroides** (p. 156), Japan; *Notaris bimaculatus* ssp. **subcostatus** (p. 158), Kamtchatka; *N.* **funebris** (p. 158), Korea; *N.* **okunii** (p. 159), *Smicronyx* **madaranus** (p. 161), and *S.* **rubricatus** (p. 161), Japan. *Gymnetron* **matsumurai** (*Cocliodes pilosus* Mats.) (p. 147). Types in Ent. Mus., Hokkaido Imp. Univ.—*R. Takahashi.*

8706. MACHULKA, VÁCLAV. Eine vergleichende Studie über das Cephennium montanum Rttr. und ihm ähnliche Arten aus Nord-Italien. *Wiener Ent. Zeitung.* 74(1): 11-18. 5 fig. 1929.—The need for a revision of the group of palearctic *Cephennium* on the basis of ♂ genitalia is suggested. *C.* **jurečeki*** (p. 14) and *C.* **tirolense*** (p. 15), Tirol; *C.* **italicum*** (p. 16), Italy; *C.* **helveticum*** (p. 17), Switzerland. An analytic key is given.—*G. Maydell.*

8707. MARSHALL, GUY A. K. On two new species of Curculionidae (Col.) from the Canary Islands. *Tijdschr. voor Ent.* 71(1/2): 114-117. 1928.—*Microlarinus* **eliasenae** (p. 114) and *Apion* **spartocytisi** (p. 115), both types in Brit. Mus. *Apion cretaceum* Rosh. (=*A. senex* Woll.).

8708. MATA, A. B., and R. O. ARAVENA. Metamôrfosis de un coleópter odel género Gratiana. *Rev. Soc. Ent. Argentina* 1(1): 31-34. 1926.—Egg, larva, nymph, and imago of *G. spadicea* Boh. are described.

8709. OBENBERGER, JAN. Specierum generis Meliboeus H. Deyrolle diagnoses praeliminares (Coleoptera, Buprestidae). *Folia Zool. et Hydrobiol.* [*Riga*] 2(2): 202-219. 1931.—List of spp., including: *Meliboeus* **zuluanus** (p. 203), Natal; *M.* **gérardi** (p. 203), Belgian Congo; *M.* **komáreki** (p. 203), East Africa; *M.* **transvalensis** abs. **cyanicolor** and **catacaustus** (p. 204), Transvaal; *M.* **malvernensis** (p. 204), Natal; *M.* **angolanus** (p. 204), Angola; *M.* **gilli** (p. 205), Cape Province; *M.* **contortulus** (p. 205) and *M.* **hirsutus** (p. 206), Transvaal; *M.* **musculus** (p. 206), Cape Province; *M.* **sericeus** (p. 206), Eritrea; *M.* **niveiventris** (p. 207), Transvaal; *M.* **pistor** (p. 207), S. W. Africa; *M.* **mulanganus** (p. 207), Kenya Colony; *M.* **aethiopicus** (p. 208), Abyssinia; *M.* **pretoriae** (p. 208), Transvaal; *M.* **sutor** (p. 208), Kenya Colony; *M.* **hottentotta** (p. 209), S. W. Africa; *M.* **parachalceus** (p. 209), Tanganyika; *M.* **croesus** (p. 209), Abyssinia; *M.* **doddsi** (p. 210), Rhodesia; *M.* **flammicoxis** (p. 210), Kenya Colony; *M.* **toroënsis** (p. 211), Uganda Protectorate; *M. t.* ssp. **buarinus** (p. 211), Cameroons; *M.* **neavei** (p. 211) and *M. n.* ab. **sapphireus** (p. 212), Uganda; *M.* **burgeoni** (p. 212), Belgian Congo; *M.* **jakobsoni** (p. 212), Sierra Leone; *M.* **karnyi** (p. 213), Belgian Congo; *M.* **victor** (p. 213), *M.* **nonfriedi** (p. 213), *M.* **indignus** (p. 214), and *M.* **strandi** (p. 215), Burma; *M.* **uzeli** (p. 215), Ceylon; *M.* **lineola** (p. 216), India; *M.* **kalshoveni** (p. 216), Java; *M.* **scintilla** (p. 217), Burma; *M.* **jakovlevi** (p. 217), India; *M.* **tchitché-**

rini (p. 218), Burma; *M.* semenovi (p. 218), India; *M.* buddhaicus (p. 218), French Indo-China.

8710. **OCHS, GEORG. Über die Gyriniden Borneo's.** *Ent. Blätter* 24(3): 98-103. 1928.—The concluding portion of a monograph on this family, with keys to spp., including *Orectochilus* subsinuatus (p. 99).—*M. H. Hatch.*

8711. **ORCHYMONT, A. d.' Notes synonymiques sur le genre Laccobius Er. (Col. Palp.)** *Bull. et Ann. Soc. Ent. Belgique* 70(1): 33-40. 1930.—The spp. treated are *L. albipes* Kewert, *L. biguttatus* Gerh., *L. bipunctatus* Fabr., and *L. striatulus* Fabr.—*H. Dietrich.*

8712. **ORCHYMONT, A. d'. Nouvelles notes sur quelques Hydraena paléarctiques.** *Bull. et Ann. Soc. Ent. Belgique* 70(9): 218-228. 1 pl. 1930.—The author disagrees with G. V. Hudson on the use of the ♂ genitalia in the classification of Coleoptera states: (1) that the difficulty of figuring a complicated structure is overcome by the use of several figures of different aspects, the problem not being unique; (2) that in ignoring the morphology of these structures important characters and relationships may be missed; (3) that in the author's experience, the variability of the genitalia is not as great as Hudson supposes; and (4) that it is true that no identification of a living insect can be made by this method. *Hydraena emarginata* Rey, ♀ discussed; *H. truncata* Rey (=*H. emarginata* Rey ♂ (not ♀)); *H. samnitica* Fiori, notes on structure; *H.* saga ♂* (p. 225), Germany.—*F. C. Fletcher.*

8713. **PIC, M. Nouveaux Coléoptères de la République Argentine.** *Rev. Soc. Ent. Argentina* 1(3): 25-26. 1927. —*Anthicus* singularis (p. 25), type in coll. Bruch; *A.* myrmecophilus (p. 25); *Phrixothrix* bruchi (p. 26).

8714. **TREMOLERAS, J. Nuevos datos ecológicos sobre Buprestidos platenses. [New ecological data on Buprestidae of La Plata.]** *Rev. Soc. Ent. Argentina* 2(4): 185-186. 1929.—A list of 28 spp., with notes on distribution and habitat.

8715. **UHMANN, E. Hispinen von Sumatras Ostküste gesammelt von Herrn Dr. L. Fulmek, nebst biologischen Bemerkungen über zwei bekannte Arten (15. Beitrag zur Kenntnis der Hispinen (Col. Chrys.).** *Misc. Zool. Sumatrana* No. 41: 1-3. 1929.—An annotated list, containing *Monochirus moestus, Hispa armigera, Rhadinosa parvula, Dactylispa debilis, D. leonardi,* and *Platypria echinogale.*

8716. **UYTTENBOOGAART, D. L. Contributions to the knowledge of the Coleoptera-fauna of the Canaries. Gran Canaria.** *Tijdschr. voor Ent.* 71(1/2): 111-113. 1928.—*Asaphidion* delatorrei (p. 111).

8717. **VITALE, FRANCESCO. Fauna coleotterologica Sicula. Scaphiidae e Histeridae.** *Atti R. Accad. Peloritana, Messina* 33: 108-146. 1929.—Keys are given to the 2 families, and to the tribes, genera, and spp. known from Sicily. The systematic list of spp. includes locality records and ecological data. A bibliography of 69 titles is appended.

8718. **WIGGLESWORTH, V. B. Observations on the "Furau" (Cicindelidae) of northern Nigeria.** *Bull. Ent. Res.* [*London*] 20(4): 403-406. 1 fig. 1929.—In the "Furau," or tiger beetle larva of Nigeria, the digestion of the prey is mainly extra-intestinal. A dark brown slightly acid fluid, which is actively proteolytic and causes blackening of the tissues, is ejected from the intestine of the larva and dissolves the tissues of the prey. The resulting fluid is swept towards the mouth by the labium and reingested. The bites of the larvae had no effect upon the skin of a monkey or of man, and there is little doubt that the larvae have no relation to the inflammatory lesion of the foot of man, which also is called "Furau" in northern Nigeria.—*Author's summary.*

8719. **YEPES, JOSÉ. Algunas etiquetas de coleópteros para las playas de Juancho (Prov. de Bs. Aires). [Some Coleoptera from the beaches of Juancho.]** *Rev. Soc. Ent. Argentina* 2(1): 41-42. 1928.—A list of 49 forms, with notes on frequency.

DIPTERA

E. T. CRESSON, JR., *Editor,* Brachycera

O. A. JOHANNSEN, *Editor,* Nemocera

(See also in this issue Entries 6211, 6306, 6317, 6321, 6984, 7533, 7799, 7820, 7822, 7823, 7824, 7826, 7028, 7830, 7831, 7833, 7835, 8632, 8638, 8647, 8655, 8843)

8720. **ALDRICH, J. M. American two-winged flies of the genus Stylogaster Macquart.** *Proc. U. S. Nation. Mus.* 78(9): 1-27. 1930.—This paper contains keys to the spp. of the genus, a discussion of generic and specific characters and the adult habits, and descriptions of the 20 known spp. from North and South America, including 12 that are new. *Stylogaster stylata* Fabr. (=*S. biannulata* v. *argentina* Kröber); *S.* decorata ♂ (p. 16), Costa Rica, type in U. S. Nation. Mus.; *S.* currani (p. 16) and *S.* banksi (p. 18), both Canal Zone, and types in Amer. Mus. Nat. Hist.; *S.* breviventris (p. 19), Brit. Guiana, type in Canadian Nat. Coll.; *S.* fasciata ♂ (p. 20), Brit. Guiana, type in Mus. Comp. Zool.; *S.* apicalis (p. 21), Honduras and Canal Zone, type in U. S. Nat. Mus.; *S.* speciosa ♀ (p. 22), Canal Zone, type in Amer. Mus. Nat. Hist.; *S.* pectinata ♂ (p. 22), Honduras and Peru, type in U. S. Nat. Mus.; *S.* rectinervis (p. 23), Brit. Guiana and Costa Rica, type in Canadian Nat. Coll.; *S.* indistincta ♂ (p. 24), Canal Zone, type in U. S. Nat. Mus.; *S.* peruviana ♀ (p. 25), Peru, type in U. S. Nat. Mus.; *S.* panamensis ♀ (p. 26), Canal Zone, type in Mus. Comp. Zool.

8721. **ALEXANDER, C. P. The crane-flies of Jamaica.** [In: **C. C. GOWDEY. Catalogus Insectorum Jamaicensis.**] *Dept. Sci. and Agr. Jamaica, Ent. Bull.* 4(3): 19-29. 2 fig. 1928.—A complete list of the Tipulidae so far discovered in Jamaica, including *Limonia* basistylata ♂ (p. 19); *Diotrepha* flavicosta (p. 23); *Eriocera* cramptoni ♂ (p. 23); *Erioptera* (*Empeda*) nymphica ♀ (p. 24); *Teucholabis* (*Teucholabis*) gowdeyi* (p. 25), type in British Mus.; *T.* (*T.*) nebulipennis ♀ (p. 27); *Tipula* (*Tipula*) jamaicensis ♀* (p. 27), type in Amer. Mus. Nat. Hist. All other types are in the author's coll. *Dicranomyia* (n. subg. **NEOLIMNOBIA**) (p. 20), based on *D.* (*N.*) diva (*Limnobia d.* Schiner) (p. 20). A total of 22 spp. of Tipulidae are recorded from the island.—*C. P. Alexander.*

8722. **ALEXANDER, CHARLES P. New or little-known Tipulidae (Diptera). XLIV. Australasian species.** *Ann. and Mag. Nat. Hist.* 5(25): 136-156. 1930.—*Dolichopeza* (*Dolichopeza*) illingworthi ♂ (p. 136) and *D.* (*D.*) davidsoni (p. 137), Queensland; *D.* (*D.*) dorrigensis ♀ (p. 138), New South Wales; *Macromastix* (*Macromastix*) clitellaria (p. 139), Victoria, type in Wilson coll.; *M.* (*M.*) mathewsi (p. 141), W. Australia; *M.* (*M.*) clarkiana (p. 142), Victoria, type in Nat. Mus., Victoria; *Limonia* (*Geranomyia*) bogongicola (p. 143), and *L.* (*G.*) grampianicola (p. 144), Victoria, types in Wilson coll.; *L.* (*Limonia*) clarki (p. 145), W. Australia, type in Macleay coll.; *L.* (*L.*) tamborina ♂ (p. 147), Queensland; *L.* (*L.*) exosa ♂ (p. 148), New South Wales; *L.* (*Libnotes*) tayloriana ♂ (p. 149), Queensland, type in Australian Inst. of Trop. Med.; *L.* (*Dicranomyia*) dicksoniae (p. 150), Victoria, type in Wilson coll.; *L.* (*D.*) dorrigensis ♂ (p. 152), New South Wales; *L.* (*D.*) flavidella ♂ (p. 153), Victoria, type in Wilson coll.; *L.* (*Idioglochina*) perkinsiana ♂ (p. 154), Queensland, type in Univ. of Queensland; *Eurhamphidia* invenustipes ♂ (p. 155), W. Australia, type in Macleay coll. Types, unless otherwise stated, are in the author's coll.

8723. **ALEXANDER, CHARLES P. New or little**

known Tipulidae (Diptera). XLV. Australasian species. *Ann. and Mag. Nat. Hist.* 5(28): 370-388. 1930.—Part of a series of Victorian eriopterine crane-flies is discussed. *Molophilus* **janus** (p. 370); **titania** (p. 372); **perluteolus** (p. 373), **flavidellus** (p. 374), **arcuarius** ♂ (p. 375), **strix** (p. 376), **alpicola** ♂ (p. 377), **chloris** ♂ (p. 379), **tasioceroides** ♂ (p. 380), **extricatus** ♂ (p. 381), **grampianus** ♂ (p. 382), **spiculistylatus** ♂ (p. 383), **grandidentatus** ♂ (p. 384), **truncatus** (p. 384), **phyllis** ♂ (p. 385), **chrysopterus** (p. 386), and **decinctus** ♂ (p. 387).

8724. **BARNES, H. F.** Two gall midges (Cecidomyidae) found in stored products. *Bull. Ent. Res.* [*London*] 20(2): 119-122. 4 fig. 1929.—*Lestodiplosis* **raphani*** (p. 119), in stored seed of *Raphanus sativum* from Denmark and Germany, possibly feeding on mites; *Arthrocnodax* **farinicola*** (p. 121), in flour in Naples, probably feeding on mites.

8725. **BARNES, H. F.** A new thrips-eating gall midge, Thripsobremia liothripis, gen. et sp. n. (Cecidomyidae). *Bull. Ent. Res.* [*London*] 21(3): 331-332. 1 fig. 1930.—**THRIPSOBREMIA** (p. 331), intermediate between the bifila and trifila groups of Cecidomyinae, type *T.* **liothripis*** (p. 331), Trinidad, predacious on *Liothrips urichi*.

8726. **BAU, ARMINIUS.** Die Dipteren-Ausbeute der Sunda-Expedition Rensch. I. Diptera pupipara. *Zool. Anz.* 88(11/12): 289-291. 1930.—Five spp. are listed, with references to the literature, distributional records, and taxonomic remarks. *Cyclopodia macrura* is new to the Sunda Is., and *C. horsfieldi* is recorded as parasitic on *Pteropus hypomelanus lombocensis*.

8727. **BOREL, E.** Nomenclature des moustiques de la Cochinchine et du sud Annam. *Far East. Assoc. Trop. Med. Trans. 7th Congr. Brit. India* 3: 165-168. 1927 [1928].—A list of genera and spp.

8728. **BOREL, E.** Sur les moeurs des Anophèles en Cochinchine. *Far East. Assoc. Trop. Med. Trans. 7th Congr. Brit. India* 3: 168-171. 1927[1928].—A tabulation showing habits and ecological relations of *Anopheles* spp. in Cochin China.

8729. **BORGMEIER, TH.** Zur Morphologie und Biologie von Pseudohypocera nigrofascipes Borgm.-Schmitz (Dipt., Phoridae). *Zool. Anz.* 90(3/4): 92-104. 11 fig. 1930.—The larvae of this fly live in bee nests (*Apis, Melipona, Trigona*). The imago (sensory hairs on the legs, ♂ hypopygium, abdominal glands, terminal segments, and genitalia of ♀) is described, and the egg, larva, and pupa described and figured. In the opening of the puparium, one piece is detached in front, which is not split in two. Despite Goidanich's statement, the author maintains that the opening of the puparium of *Apocephalus schmitzi* takes place in the same way as in *Megaselia scalaris* and *rufipes*. Some biological observations made by Pickel are discussed. Probably, the larvae of *Pseudohypcoera* feed on pollen.—*T. Borgmeier*.

8730. **BORGMEIER, TH.** Über das Vorkommen der Larven von Hermetia illucens L. (Dipt., Stratiomyidae) in den Nestern von Meliponiden. *Zool. Anz.* 90(9/12): 225-235. 8 fig. 1930.—A large number of larvae* of this fly, together with *Pseudohypocera nigrofascipes*, were taken from nests of Meliponidae. Statements of authors concerning the same fly on bee-hives are discussed, and a detailed description of the larva is given.—*T. Borgmeier*.

8731. **BROMLEY, S. W.** A review of the genus Proagonistes, Loew (Diptera, family Asilidae), with descriptions of eight new species. *Ann. and Mag. Nat. Hist.* 6(32): 209-224. 1 pl., 2 fig. 1930.—The characteristics of the genus are given and a note on distribution and a key to spp. A total of 16 spp. are now known, including: *Proagonistes* **auripes** ♂ (p. 215), Malay Peninsula, type in Hamburg Mus.; *P.* **apicalis** (*Lamyra a.* Curran) (p. 216); *P.* **leoninus** (p. 216), San Thomé, type in British Mus.; *P.* **mystaceus** ♂ (p. 218), Kenya Colony, type in Brit. Mus.; *P.* **vulpinus** ♂ (p. 219), San Thomé, type in Brit. Mus.; *P.* **gigantipes*** ♀ (p. 219), Madagascar, type in Brit. Mus.; *P.* **rufibarbis** (*Laphria r.* Fabr.) (p. 220); *P.* **ufens** (*Laphria u.* Walker) (p. 220); *P.* **praeceps** (*Laphria p.* Walker) (p. 220); *P.* **saliodes** ♀ (p. 221), Nyasaland; *P.* **austeni** (p. 221), Nyasaland, type in Brit. Mus.; *P.* **neavei** (p. 223), Uganda, type in Brit. Mus.

8732. **COLE, A. C. Jr.** Muscina stabulans Fall. (Diptera: Muscidae) parasitic on Arachnara subcarnea Kell. (Lepidop.: Noctuidae). *Ent. News* 41(4): 112. 1930.—The host pupa appeared in the stalk of *Typha latifolia* at the end of its larval burrow, about 4 in. under the surface of the water. The author observed adult *Muscina stabulans* flying around *Typha latifolia* infested with *Arachnara subcarnea*, but egg-laying was not observed. Since the host larvae enter *Typha* leaves at the tip, it is possible that they are parasitized in this instar. This is probably the first recorded observation of distinct parasitism in *M. stabulans*.

8733. **COLLIN, J. E.** New species of Borboridae (Diptera). *Ent. Month. Mag.* 66(788): 18-21. 1 pl. 1930.—*Borborus* **similis*** (p. 18), *Limosina* **palustris*** (p. 19), and *L.* **spinosa** ♂ (p. 20), all 3 England, and types in author's coll.—*H. M. Gilkey*.

8734. **CRESSON, EZRA T. Jr.** Descriptions of new genera and species of the dipterous family Ephydridae. Paper 8. *Ent. News* 41(3): 76-81. 1930.—*Ditrichophora* **painteri** (p. 77), and *D.* **balsamae** ♀ (p. 77), Honduras; *Polytrichophora* **boriqueni** (p. 77), Porto Rico, type in New York Acad. Sci.; *Hecamedoides* **buccata** (p. 78), New Jersey; *Allotrichoma* **salubris** (p. 78), Brazil; *Axysta* **bradleyi** ♂ (p. 79), Georgia, type in Cornell Univ.; *Nostima* **quinquenotata** ♀ (p. 79), Maryland, *N.* **niveivenosa** ♀ (p. 80), Porto Rico, *Hydrina* **nigrescens** ♂ (p. 80), British Columbia, and *H.* **macquarti** ♂ (p. 80), Alaska, types of all 4 in U. S. Nation. Mus.; *Napaea* **halteralis** (p. 81), Washington; *Parydra* **incommoda** (p. 81), Idaho. When not otherwise specified, types are in Acad. Nat. Sci., Philadelphia.

8735. **CURRAN, C. H.** New Diptera belonging to the genus Mesogramma Loew (Syrphidae). *Amer. Mus. Novitates* No. 405. pp. 1-14. 3 fig. 1930.—A key to 48 spp. is given, the first published for *Mesogramma*. The author states that the Kertesz catalog is in error in placing *M. tridentatum* Giglio-Tos as a synonym of *M. duplicatus* Wied. *M.* **productus** (p. 5), Ecuador; *M.* **watsoni*** (p. 5), West Indies; *M.* **difficilis*** (p. 6), Porto Rico and British Guiana; *M.* **taenia*** (p. 7) and *M.* **lutzi** ♀ (p. 7), Canal Zone; *M.* **slossonae** ♂ (p. 8), Florida; *M.* **nitidiventris** ♂ (p. 9), Brazil; *M.* **norma** ♂ (p. 10), *M.* **purus** ♂ (p. 10), and *M.* **clara** (p. 11), Canal Zone; *M.* **panamensis** ♂ (p. 12), Panama; *M.* **mitis** ♀ (p. 13), Jamaica; *M.* **vierecki** ♀ (p. 13), Colombia.

8736. **GAVER, F. van, et J. TIMON-DAVIS.** Études sur les Diptères Brachycères des environs de Marseille. *Ann. Soc. Ent. France* 97(1/2): 1-17. 1928.

8737. **HAMLYN-HARRIS, R.** Notes on the breeding-places of Aëdes (Finlaya) notoscriptus, Skuse, in Queensland. *Bull. Ent. Res.* [*London*] 19(4): 405-409. 1929.—Observations have shown that this mosquito seeks alkaline waters, as a rule, and avoids acid waters.

8738. **HELLÉN, WOLTER.** Zur Kenntnis der sibirischen Arten der Gattung Chilosia Meig. (Dipt.) [In German.] *Notulae Ent.* [*Helsingfors*] 10(1): 26-29. 4 fig. 1930.—An annotated list of spp., including: *C.* **kamtschatica** ♀* (p. 26), Kamchatka; *C.* **albohirta*** (p. 28), Transbaikalia; *C.* **reniformis** ♂* (p. 28), "Jenisseisk"; *C.* **magnifica*** (p. 29), E. Siberia. Types in Zool. Mus. Helsingfors.

8739. **HOWLAND, L. J.** The nutrition of mosquito larvae with special reference to their algal food. *Bull. Ent. Res.* [*London*] 21(4): 431-439. 1 pl., 3 fig. 1930.—Algae are ingested by many spp. of mosquito larvae and appear to form an important part of the food of these larvae. The algae are digested in the gut, but the digestion is often by no means complete. It is quite possible that the rôle played by the algae may also be assumed by other forms of organic matter, for larvae may be reared to maturity in solutions containing little or no algae. Different algae react differently in the guts of the larvae, some being noticeably digested and some

hardly at all. Those algae which are digested the most are easily stained and are forms of low osmotic pressure. Cytological investigations revealed no character that indicates that algae are an especially nutritious diet.—*Author's summary.*

8740. JOHANNSEN, O. A. Notes on the synonymy of some New York state Chironomidae. *Jour. New York Ent. Soc.* 34(3): 273-277. 1926.—*Heteromyia flavipes* Meigen (=*Ceratopogon basalis* Walker); *Tanypus tricolor* Loew belongs to the genus *Coelotanypus; T. melanops* Wied. (=*Chironomus unicolor* Walker); *T. nigropunctatus* Straeger is distinct from the American spp. bearing this name; *Orthocladius* **atomarius** (*Chironomus a.* Zett.) (p. 274); *Chironomus sordidellus* Zett. belongs to the genus *Psectrocladius; C. atratulus* Zett. belongs to the genus *Metriocnemus; Chironomus gmundensis* Egger is a *Tanytarsus; Tanytarsus* **flavellus** (*Chironomus f.* Zett.) (p. 274); *C. pellucidus* Walker belongs to the genus *Tanytarsus*, with *T. exiguus* Joh. as a synonym; *C. trichomerus* Walker is a *Tanytarsus; C. albistria* Walker, descriptive notes; *Chironomus plumosus* L. (=*C. annularis* DeG.). The author agrees with Edwards that *C. ferrugineo-vittatus* Zett. is a pale variety of *C. plumosus* L.; *C. hilaris* Walker and *C. nephoterus* Mitch. are identical; *C. glacurus* Wied. (=*C. stigmaterus* Say).

8741. LEESON, H. S. Variations in the wing ornamentation of Anopheles funestus, Giles. *Bull. Ent. Res.* [*London*] 21(4): 421-428. 5 fig. 1930.—Nine distinct arrangements of the wing scales were observed in a random sample of 1,084 individuals. Nearly 9/10 of the specimens occurred in one group, in which there were dark and pale forms. Variations in wing markings are not solely related to sex or to habitat. The pale form was more prevalent in the wet season and the dark form in the dry season. It is suggested that further study may reveal whether the dark form is the hibernating variety and whether one form is more important as a carrier of malaria than the other, and that these details of wing ornamentation should be recorded in future.—*Author's summary.*

8742. MANALANG, C. Morphology and classification of the Philippine variety of Anopheles aconitus Donitz, 1902, and Anopheles minimus Theobald, 1901. *Philippine Jour. Sci.* 43(2): 247-260. 1 pl. 1930.—A brief review of the literature on the Philippine *A. funestus* group, and rulings on the nomenclature are given. Morphological study of a series of adult mosquitoes of this group and the larval skins from which they were bred is discussed. A consideration of the principal characters of the local mosquitoes and those described from Ceylon, Assam, Java, and Malaya shows that there exists a variety of *aconitus* (var. **filipinae**) (p. 258) in the Philippines which has heretofore been classified as a variety of *A. minimus*. The local *minimus* is believed to be identical with *A. funestus* (Giles, 1900) emended by Strickland, 1924.—*C. Manalang.*

8743. ROUBAUD, E., et C. TOUMANOFF. Sur une race physiologique suractive du moustique commun, Culex pipiens L. *Bull. Soc. Path. Exotique* 23(2): 196-201. 3 fig. 1930.—Roubaud had previously announced the existence of what he calls an "autogenous" strain of the species *C. pipiens*, distinguished by ability to dispense with hibernation and to lay eggs without having sucked blood. He here discusses the differences between the ordinary, "heterodynamic," strain, blood-sucking by necessity, and the "homodynamic" strain, which is only incidentally blood-sucking. Abdominal sections show that the ♀ of the latter strain possesses, as its sole distinction, a hugely developed mass of adipose tissue, in comparison with the ordinary strain. The ordinary, hibernating strain appears to be rural in its habitat; the autogenous, non-hibernating strain seems to be adapted to the artificial conditions of urban existence.

8744. SCHMITZ, H. Die Verwandtschaft und Abstammung der Phoriden. *Natuurhist. Maanblad* [*Limburg*] 15(6): 69-76. 4 fig.; (7): 82-84. 1 fig. 1926.

8745. SCHMITZ, H. Zur Anatomie der Phoriden. *Natuurhist. Maanblad* [*Limburg*] 15(8): 92-104. 10 fig. 1926.

8746. SCHUURMANS-STEKHOVEN, J. H. Jr. Tabanids collected in Celebes and adjacent isles. *Zool. Anz.* 92(3/4): 109-111. 1 fig. 1930.—A report on the following 3 spp. collected by A. Reyne: *Tabanus succurvus*, Sangi Archipelago; *T. reducens* and *T.* **aurantiacus** ♀* (p. 110), both Celebes.

8747. [STAKELBERG, A. A.] ШТАКЕЛЬБЕРГ, А. А. О нахождении Nycteribosca kollari Frfld. (Diptera, Streblidae) в Туркестане. [N. kollari in Turkestan.] Русское Энтомологическое Обозрение. (*Rev. Russe d'Ent.*) 22(1/2): 133. 1928.—In the Bokarda cave near Askabad (Transcaspia] are found: *Nycteribosca kollari, Nycteribia schmidli*, and *Penicillidia conspicua*, all, for the most part, on *Miniopterus schreibersi pallidus.*—*G. Maydell.*

8748. TAYLOR, FRANK H. Notes on Australian Culicidae (Dipt.). *Bull. Ent. Res.* [*London*] 20(3): 271-277. 1 pl. 1929.—*Ficalbia elegans* ♀*, emended description; larva and pupa also described of this sp. and of *Mimomyia metallica**, [*Aëdes*] (*Chaetocruiomyia*) **wattensis** ♀ (p. 275), Queensland; [*A.*] (*C.*) **tulliae** ♀ (p. 275), Queensland; [*A.*] (*C.*) **moloiensis** ♀ (p. 276), Queensland; [*A.*] (*C.*) **elchoensis** (p. 276), Elcho Is., North Australia. Types are in Australian Inst. of Tropical Medicine, Townsville.

8749. TAYLOR, FRANK H. The Anopheles of the Australian region, their bionomics and their distribution. *Far East. Assoc. Trop. Med. Trans. 7th Congr. Brit. India* 3: 143-164. Map. 1927[1928].—The life-histories of most spp. are fairly well known; their range is not so well known. The spp. of the subg. *Anopheles* are shown to be fairly closely related; *annulipes* and *amictus* of the subg. *Myzomyia* still require considerable research before the status of the various forms is established. *Bironella gracilis* Theob. has for the present at least been retained as generically distinct from *Anopheles.* The definite relation of the various spp. to malaria has been shown to be entirely lacking, except in the case of *A. punctulatus* and its variety *moluccensis*, which were proved by Heydon to be natural vectors at Rabaul. The evidence concerning *A. annulipes*, though presumptive, is not convincing inasmuch as the blood of the patient had not been examined before he settled in the Sydney district (Money, 1926). The position of *A. amictus* and *A. bancrofti* is rendered even more obscure since *A. punctulatus* and var. *moluccensis* are both found in North Australia where both *amictus* and *bancrofti* occur in numbers, and where epidemics of malaria have from time to time occurred. In Queensland, and North Queensland in particular, apparently the prevailing sp. is *A. amictus* with a mixture of *A. bancrofti* and to a much less degree, if at all, of *A. annulipes.* The possibility of the presence of *A. punctulatus* and var. *moluccensis* can not be excluded. *Punctulatus* occurs well down the western side of the Gulf of Carpentaria as most probably also does its variety; it may therefore be found also on the Cape York Peninsula. Should they be so found, it would explain the epidemics which have occurred in the past. Malaria has practically disappeared from Cairns; this the writer thinks is due to the fact that all the important anopheline breeding-places in that locality have been filled in or destroyed in recent years. A map of Australia shows the known distribution of *Anopheles* spp.

8750. THIENEMANN, AUGUST. Chironomiden-Metamorphosen 1. *Arch. Hydrobiol.* 19(4): 585-623. 31 fig. 1928.—The Ceratopogoninae are divided into 3 sections on the basis of larval and pupal characters: (1) Ceratopogoninae genuinae, body of larva with conspicuous setae or spines; anterior and posterior prolegs well developed; pupae with at least 1 pair of slender thoracic processes, the prothoracic respiratory organs more or less piriform; (2) C. intermediae, body of larva with inconspicuous setae; a retractile caudal proleg present; pupae without long thoracic tubular processes;

prothoracic respiratory organ slender bandlike, or slender clavate. This section contains only *Dasyhelea* Kief. (*Pseudoculicoides* Mall., *Prokempia* Kief.) with the spp. divided into the groups *longipalpis, diplosis,* and *halophila;* (3) C. vermiformes, body of larva slender with inconspicuous setae, no prolegs present; pupae lacking tubular processes, the prothoracic respiratory organ more or less piriform. The 1st group of this section comprises the genus *Culicoides,* the 2nd group, such genera as *Bezzia, Probezzia, Palpomyia, Dicrobezzia Johannsenomyia,* and *Xylocrypta.* Keys to larvae and pupae are given together with a check-list of spp. of which the immature stages are known.—*O. A. Johannsen.*

8751. TRENSZ, F. Recherches sur l'index maxillaire de Anopheles maculipennis. (Note préliminaire.) *Bull. Soc. Path. Exotique* 23(1): 43-47. 1930.—On the basis of studies of 4,244 specimens from Algeria, Italy, and continental France, the author finds that the average index fails to support the theory of differentiation into types. [See also the following abstract.]

8752. ROUBAUD, E. Quelques remarques à propos de l'interprétation théorique des index maxillaires. *Bull. Soc. Path. Exotique* 23(1): 47-53. 1930.—The author's facts tend to show that the maxillary index is modified according to feeding habits [on man or on lower animals] of the mosquito in the given region. [See also the preceding abstract.]

8753. VAN DUZEE, M. C. Three new dolichopids from California and Colorado (Diptera). *Pan-Pacific Ent.* 6 (3): 123-126. 1930.—*Pelastoneurus* latifacies (p. 123), type in author's coll., and *Dolichopus* subcostatus (p. 124), type in California Acad. Sci., both California; *D.* nigroapicalis (p. 125), Colorado, type in California Acad. Sci.

8754. VAN DUZEE, M. C. The dipterous genus Sympycnus Loew in North America and the West Indies. *Pan-Pacific Ent.* 7(1): 35-47. 1930.—A history of the genus is given, with key to the ♂♂ of N. America, Mexico, and the West Indies. *Sympycnus* Loew (=*Nothosympycnus* Wheeler, *Gymnoceromyia* Bigot). The characters of the genus are given and the following described as new: *S.* aldrichi ♂ (p. 39), Indiana, type in U. S. Nation. Mus.; *S.* breviventris (p. 40), California, *S.* calcaratus (p. 41), Colorado and New Mexico, *S.* globulicauda ♂ (p. 43), Colorado, *S.* inaequalis (p. 44), California, *S.* laevigatus (p. 45), California, and *S.* latitarsis ♂ (p. 46), Utah, types of all 6 in author's coll.; *S.* montanus ♂ (p. 47), Idaho, type in U. S. Nat. Mus. The following are described as new in the key: *S.* thoracicus ♂ (p. 37), St. Vincent, W. I.; *S.* pulvillus ♂ (p. 38), Colorado; *S.* tripilus ♂ (p. 38), California; *S.* setosus ♂ (p. 38), Colorado.

8755. WIGGLESWORTH, V. B. The early stages of some West African mosquitoes. *Bull. Ent. Res.* [*London*] 20(1): 59-68. 7 fig. 1929.—Descriptions are given of the larvae and pupae of *Uranotaenia nigripes*, Hodgesia sanguinis*, H. malayi** (larva only), *Aëdes punctocostalis*, A. abnormalis*, A. tarsalis*,* and *Ficalbia malfeyti*. H. sanguinis* is remarkable chiefly for the structure of the respiratory trumpets of the pupa, each of which is cleft almost to the base in the form of two leaflets.—*From author's summary.*

HEMIPTERA AND HOMOPTERA

(p. 57); *P.* nitidulus (*Mesostenus nitidus* Provan.) (p. 58); *Thysiotorus* triangularis (*Mesoleptus t.* Cresson) (p. 58); *Gambrus* canadensis (*Nematopodius c.* Provan.) (p. 58).—*R. A. Cushman.*

8783. DELMAN, R. Première liste de Symphytes des Pyrénées. *Bull. Soc. Hist. Nat. Toulouse* 56(3): 463-468. 1927.—A classified enumeration of several scores of Tenthredinini.

8784. EIDMANN, H. Weitere Beobachtungen über die Koloniegründung einheimischer Ameisen. *Zeitschr. Wiss. Biol., Abt. C Zeitschr. Vergleich. Physiol.* 7(1): 39-55. 2 fig. 1928.—The fertilized queen of *Lasius niger* L. overwinters in a burrow and begins egg-laying the following spring. First, a single larva is reared; after it pupates, other eggs develop. The 1st worker emerges 1 year after the isolation of the queen in her burrow, and opens a passage to the outside. Workers lay no eggs when a queen is present. Necessary conditions for the welfare of the workers are the presence of a queen in the nest and (of secondary importance) the exercise of the instincts for construction and for the care of the brood. The ♀ of *Lasius mixtus* Nyl., after her nuptial flight, has about 4 weeks in which to procure the aid of auxiliary ants for founding her colony. Polygyny in the nest of *Formica rufa* L. is brought about chiefly as follows: workers seize fertilized ♀♀ after their nuptial flight, drag them into the nest and retain them there as auxiliary queens. If, after having once founded her colony, the queen of *Myrmica rubra* L. be isolated, she is unable to repeat the process and soon dies; she does not lose her instinct of caring for the brood but she will not lay eggs unless workers are present.—*G. C. Wheeler.*

Australian Mus., except where otherwise given. Distributional and taxonomic notes are given on numerous other spp.

8789. GOIDANICH, ATHOS. Reperti biologici e morfologici sul Crabro (Coelocrabro) podagricus Vander Linden. [Biological and morphological notes C. (C.) podagricus.] *Boll. Lab. Ent. Ist. Superiore Agrar.* [*Bologna*] 1: 96-106. 3 fig. 1928.—Descriptions are given of the nesting ♀, of the nest and the provisioning of it with Diptera (*Scatopse pulicaria* Loew). Morphology of the *Crabro* larva is given and compared with other known larvae of the genus.—*A. Goidanich* (*transl.*).

8790. GOURLAY, E. S. Notes and descriptions of New Zealand Hymenoptera. *Trans. and Proc. New Zealand Inst.* **59**(2): 368-373. 1 fig. 1928.—Notes are given on *Limnerium muelleri* Butler; *Aspicolpus hudsoni* v. **castanea** (p. 369); *Doryctes* **pallida** ♂ (p. 369); **NEOSOLINDENIA** (p. 370) (Encyrtidae), near *Solindenia*, type *N.* **cyanea** (p. 370), parasitic on *Limneria mulleri* Butl., type in Cawthron Inst.; *Polymoria* **barteli** (p. 371); *Thaumasura* **resplendens*** (p. 373), type in Hudson coll.

8791. HARUKAWA, CHUKICHI, and SABURO KONDO. Studies on the rush saw-fly. III. Relation of temperature to the development of the rush saw-fly. *Ber. Ōhara Inst. Landw. Forsch., Japan* 4(2): 181-198. 6 fig. 1929.—Investigations on the relation of temp. to egg development and also to growth of the rush saw-fly (*Tomostethus juncivorus* Rohwer), were carried out under constant as well as under variable temp. The initiation to egg development seemed to be slightly lower than 10° C.; the maximum temp., slightly higher than 30° C., and the optimum about 27° C. The minimum temp. for the growth of larva was about 12° C. and the maximum seemed to be 27-28° C. The temp. of the maximum velocity of growth lies at about 25° C., but the death rate of the larva was larger at this temp. than at 20° C. Two races of rush saw-fly were experimented upon and they were found to differ to some extent in their responses to temp.—*C. Harukawa.*

8792. HINGSTON, R. W. G. The habits of Oecophylla smaragdina. *Proc. Ent. Soc. London* 2(3): 90-94. 1928.—The nest and its construction and mode of capturing prey are described.

8793. KARAWAJEW, W. Ein Fall von lateralem Hermaphroditismus bei Ameisen und ein Fall defekter Körperbildung. *Folia Myrmecologica et Termitologica* 1(4/5): 45-47. 1 fig. 1927.—A specimen of *Bothriomyrmex communista* is described in which the left side of the head is ♂ and the right ♀, the eye however on the ♀ side is that of a worker. The thorax is partly hermaphroditic, the right side being characteristic of a worker; the gaster is entirely ♀. A specimen of *Megaponera foetens* from Africa is described which entirely lacks the petiole, which in all other respects is normal.

8794. KOSTYLEV, GEORG. Materialien zur Kenntnis der Vespidenfauna der östlichen Krim. *Ent. Mitteil.* 17(6): 398-407. 9 fig. 1928.—One species of Masaridae and 29 spp. of Eumenidae are recorded from this region. *Microdynerus* **wuczeticzi*** (p. 406); *Odynerus germanicus* v. **ponticus** (p. 402). A key is given to the spp. of *Odynerus* belonging to the so-called subg. *Lionotus* which includes 16 spp. *Hoplomerus melanopygus* Bir., *H. jacobsoni* Bir., and *H. mimeticus* Sch. & Fr. are treated as subspecies of *H.* (=*Paravespa*) *rex* Schulth. and Friese (p. 399). The author also states that *Odynerus vagus* Rad. is not a variety of *O. transitorius* Mor., but is a synonym of *O. jucundus* Mocs. *O. ephippium* Germ. (=*O. dubius* Sauss., = *O. opacus* Mor.). Types in Zool. Mus. Univ. of Moscow.—*C. E. Mickel.*

Omsk, USSR.*) 9(1/5): 199-211. 2 fig. 1928.

8804. POULTON, [E. B.] The fertilization of orchids of the genus Ophrys by the males of Hymenoptera Aculeata. [To be cont'd.] *Proc. Ent. Soc. London* 2 (1): 31-32. 1927.—*Ophrys speculum* is fertilized by the scoliid, *Dielis ciliata* F., which carries the pollinia on its head. *O. lutea* is fertilized by *Andrena nigro-olivacea* Dours and *A. senecionis* Perez. *O. fusca* is fertilized by *A. trimmerana* Kirb. and *A. nigroaenea* v. *nigrosericea* Dours.

8805. REICHENSPERGER, A. Eigenartiger Nestbefund und neue Gastarten neotropischer Solenopsis-Arten. *Folia Myrmecologica et Termitologica* 1(4/5): 47-51. 1927.—From a nest of *S. saevissima tricuspis* found floating in the river Passa-Tres (Brazil), the following inhabitants were identified: *S. saevissima* in all stages from the winged and wingless ♀♀ to the youngest larvae. A number of *Loelaps*-like mites; over 400 specimens in all stages of the hemipteron *Neoblissus parasitaster;* 3 proctotrupid Hymenoptera sp. unknown; 18 *Myrmecosaurus gallardoi,* a staphylonid, and 5 specimens of species of *Myrmecochara. Myrmecochara* **tricuspidis** (p. 49), from a nest of *Solenopsis iheringi* and *M.* **santschi** (p. 50), both from Brazil; a key to the Brazilian spp. being given.

8806. ROMAN, A. Entomologische Ergebnisse der schwedischen Kamtchatka-Expedition 1920-1922. 10 Ichneumonidae, subfam. Ichneumoninae. *Arkiv Zool.* [*Stockholm*] 19A(2. No. 7); 1-19. 1927.—The author finds much in common between the ichneumonid fauna of Kamchatka and that of Scandinavia, and explains this on the theory that both originated in the region lying between. He finds very little in common between the fauna of Kamchatka and that of Alaska and the Kurile Isls., these being derived from more southern faunae. The list of spp. includes 39 previously described and 6 new spp. and 1 new variety. *Triptognathus uniguttatus fumigator* Grav. (=*Ichneumon figulus* Er.); *Ichneumon* **latitarsis** (p. 5); *I.* **malaisei** (p. 6); *I.* **kamtschaticus** (p. 8); *I. stigmatorius* Zett. (non Hgn. Thn.) (="*melanurus* W." Thn.); *I.* **modestus** (p. 10); *Stenichneumon homocerus* W. (=*Ctenochares slavonicus* Kiss); *Cratichneumon* **laevidorsis** (p. 13), Taporkoff Isl.; *C.* **verticinus** (p. 14); *Phaeogenes tegularis* v. **nigrifemur** (p. 17). Except where otherwise given, new spp. are from Kamchatka. Types of new forms in Stockholm Mus.—*R. C. Cushman.*

8824. CALVERT, PHILLIP P. The generic characters and the species of Palaemnema (Odonata: Agrionidae). *Trans. Amer. Ent. Soc.* 57 (1) : 1-111. 21 pl., 2 fig. 1931.—Much more extensive material (364 ♂, 79 ♀) than was accessible to previous students justifies the publication of this paper. The types of *P. paulina* Drury 1773, *P. angelina* Selys 1860, *P. desiderata* Selys 1886, and *P. clementia* Selys 1886, are apparently lost; their history, as far as known, is given. Some data concerning the last 2 were obtained from colored drawings by de Selys preserved in the Brussels Mus., and drawings by Hagen of the appendages of, probably, the type of *angelina* Selys are at the Mus. Comp. Zool. Types of other spp. described previous to 1930 have been studied. Variations in the family, subfam., and generic characters, as found in the material of *Palaemnema* examined, are given in detail, often in percentages. Some of the venational variations* reproduce a normal character of the Old World *Alloneura, Nososlicta* and *Isosticta* and the New World *Protoneura* and allies. Special attention is paid to the penis as a specific character; it is believed that this organ retains its shape even when dried. The genus is now known from the State of Puebla, Mexico, 20° north, 98°W., to southern Peru, 10°S., and northern Venezuela, 67°W., and from sea level up to 2000 M. (6560 ft.) in Colombia; the species are all forest dwellers. No species has yet been reported from Salvador, Nicaragua, Ecuador, or northern Peru, and very few individuals have been found on the Pacific slope from Mexico to central Costa Rica. The collections examined from outside of Costa Rica were made in the months Jan. to July only. Special attention was given to the seasonal distribution of this genus in Costa Rica, during a year's continuous residence in that country, with the result that on the Atlantic slope, where no sharp distinction of wet and dry season can be made, owing to the frequent rains, imagoes (7 spp.) were found only between April 13 and August 10, with exception of a single ♂, Nov. 6. On the Pacific slope 2 spp. only were found on August 13-15, September 3, 4, and October 17; both spp. occur on the Atlantic slope also. All these dates from the Pacific slope fall in the wet season, which, on that slope, is quite distinctly marked from the dry season. Separate keys to the ♂♂ of 25 spp., and to the ♀♀ of 13 spp. are given. All species are described and figured in detail, and notes on habitats and habits are given under many of them. *P.* **paulirica*** (p. 32) and *P.* **distadens*** (p. 35), Costa Rica; *P.* **paulicoba*** (p. 45), *P.* **paulitoyaca*** (p. 47), *P.* **paulicaxa*** (p. 54) and *P.* **paulitaba*** (p. 56), Mexico; *P. angelina** Selys 1860 (=*P. paulina* Williamson 1915, *P. paulina* Kennedy 1917, *P. paulina* forma *b* Ris 1918); *P.* **mutans*** (p. 63), Venezuela; *P.* **gigantula*** (p. 72), Costa Rica; *P.* **brucei*** (p. 75), Panama, Colombia; *P.* **azupizui*** (p. 78), Peru; *P.* **reventazoni*** (p. 85), Costa Rica; *P.* **croceicauda*** (p. 96) and *P.* **edmondi*** (p. 99), Colombia; *P.* **chiriquita*** (p. 100), Costa Rica. Types of *paulirica, distadens, paulicoba, paulicaxa, paulitaba, gigantula, reventazoni,* and *chiriquita* are in Academy Nat. Sci. Philadelphia; of *paulitoyaca* in the Brit. Mus.; of *mutans, brucei, croceicauda,* and *edmondi* in coll. Univ. of Michigan Mus. Zool.; of *azupizui* at Cornell Univ.—*P. P. Calvert.*

Hemerobiidae: *Nusalala* **gradata*** (p. 195). New spp. from Siberia; types in author's coll.

8839. **NEVIN, F. REESE. A study of the larva of Calopteryx (Agrion) maculata (Odonata: Agrionidae).** *Trans. Amer. Ent. Soc.* [*Philadelphia*] 55(4): 425-448. 1 pl. 1929.—Eggs of *Agrion* (*Calopteryx*) *maculata* laid in the stem of *Lysimachia nummularia* obtained on July 4, 1928, near Philadelphia began hatching July 19th. Fed with various small ostracods and copepods some of these passed to the 5th instar. Death probably resulted from unnatural causes. Larvae in the sextult instar were obtained Sept. 15th. These transformed in early May. The following characters were more or less constant: First antennal joint long, second dark; eyes never approach one another; horn in post-ocular region; one movable hook on each labial palp; legs long and slender with 2 tarsal claws; legs more distinctly banded in successive molts; tracheal gills differed slightly in coloration and became distinctly 3-sided in later instars. Measurements on larvae of structures thought to be of taxonomic value were made microscopically. Feeding habits and locomotion are described for larvae and adults. Transformation of larva and mating habits of adults are also described. Summary of further changes: Antennae become more black and differently marked, antennal joints increase from 3 in first, 4 in second, 5 in fourth, to 7 in the quintult and succeeding instars; from 5th instar width of the mentum exceeds its length; notch in cleft distinct in 3rd instar; minute seta at base of the movable hook is not distinguishable in later instars; fixed hooks of the palps increase from 1 to 4; setae on the medium lobe are minute and gradually increase in length; wing-pads are first present in the sextult instar, the metathoracic reaches the 1st abdominal tergite in quintult and to 5th in the last; tarsus one-jointed in the first 2 instars, 2-jointed in the third and 3-jointed in following instars: abdomen became darker and different in color pattern later than originally; mandibular differences exist. A tentative key to larval instars is included.—*F. R. Nevin.*

8840. **[PLIGINSKII, V. G.] ПЛИГИНСКИЙ, В. Г. Новый вид рода Boreus Latr. (Neuroptera, Panorpidae.) [A new sp. of Boreus.]** Русское Энтомологическое Обозрение. (*Rev. Russe d'Ent.*) 24 (3/4): 230-231. 1930.—*B.* **semenovi** ♂ (p. 230), "Uisk mountain range," type in Zool. Mus. Acad. Sci. Leningrad. A key is given to the ♂♂ of the Palaearctic spp. of *Boreus*, and the distribution of the genus is discussed.

8841. **SHORTESS, S. IRVINE. Variations in wing reticulation and size of Erythrodiplax berenice with regard to geographical distribution (Odonata: Libellulidae).** *Trans. Amer. Ent. Soc.* 55(4): 415-423. 1929. —Specimens were examined from 21 localities along the east coast of the U. S. A., from Sachem Head, Connecticut, to Colon, Panama. Little variation was found in

length of wings and abdomen. A rather steady decrease was noted in the number of cells along the hind margin of the wings, in specimens collected from north to south. The group from Matagorda, Texas, showed marked similarity to the Connecticut group. No correlation was found between length of wing and wing reticulation. Variation in wing reticulation of specimens studied was not closely enough correlated with either mean annual temp. or precipitation, of their respective localities, to justify the opinion that either one is the sole factor leading to variation.—*S. I. Shortess.*

8842. **[UÉNO, MASUZO.] [Key to Japanese Mayfly nymphs (Ephemeroptera).]** [In Japanese.] *Trans. Kansai Ent. Soc.* 1. p. (27)-(36). 3 pl. 1930.—Nymphs of 18 genera are described in Japanese and 16 genera are illustrated.

8843. **[UÉNO, MASUZO.] [Mayfly nymph and chironomid larva.]** [In Japanese.] *Trans. Kansai Ent. Soc.* 1. p. (46)-(48). 2 fig. 1930.—*Trissocladius equitans* nymph* parasitized by *Rhithrogena* larva*; *Phaenocladius* nymph* parasitized by *R. aurantiaca**; *Ecdyonurus* nymph parasitized by a chironomid.

8844. **VALLE, K. J. Materialien zur Odonatenfauna Finnlands. I. Über Aeschna elisabethae Djak. in Finnland.** *Notulae Entomologicae* [*Helsingfors*] 9(1): 14-27. 4 fig. 1929.—A detailed description of *A. elisabethae** Djakonov based on 22 ♂♂ and 10 ♀♀ from Finland, and comparisons with *A. subarctica* E. M. Walker from N. Amer. and *A. juncea** are given. The Finnish and Russian *elisabethae* is held to be a separated, Old World race of *A. subarctica*, as the differences are slight and are chiefly in the lateral, thoracic stripes and in the ♂ appendages. *Elisabethae* is distributed over almost all Finland to 69° N. lat. Little is known of its habits; it appears to be a species of the moor waters.—*P. P. Calvert.*

8859. BELLOC, G. Hydrographie et océanographie. La croisière de la "Tanche" en juillet-août 1928. *Rev. Trav. Office Pêches Maritimes* 2(1): 13-29. 17 fig. 1929.—Studies were made in the Gulf of Gascony to get data for a food fish map. Apparatus used: Marti and Langevin-Florisson apparatuses, and Lucas sounding machine. Charts are given of temp. at various depths; bathymetric and geographic charts of fishes; locality lists of fishes and crustaceans, and list of plankton abundant in the upper zones. The latter was particularly rich in *Leptocephalus* larvae and larval phyllostomes and amphipods, in contrast to 1927 results; also in larval scopelids and clupeids. *Scombresox saurus* was lacking; cephalopods only found as stomach content of tunnies. Depth trawling showed a coral reef at Lat. 45° 01′ 5″ N., 2° 26′ 8″ W., and a wreck, which were signalled to fishermen. Studies on the stock of fish showed numerous *Merlucius merluccius*, chiefly immature and tunnies (distributional map of tunnies and their food given), also many *Carcharias glaucus* and *Oxyrhina spallanzani* and a large number of cetaceans.—*F. LaMonte.*

8860. [BERG, L. S.] БЕРГ, Л. С. Классификация отряда Esociformes. [Classification of the order Esociformes.] Известия Академии Наук СССР., Отделение Математических и Естественных Наук. (*Bull. Acad. Sci. URSS., Cl. Sci. Math. et Nat.*) 1931(3): 461-462. 1931.—The author recognizes only 2 families in this order: Esocidae, with 1 genus of 8 spp., and Umbridae, comprising the genera *Umbra, Novumbra,* and *Dallia.* Diagnoses are given of these 2 families. The families Novumbridae and Dalliidae are placed in the synonymy of the Umbridae. Provisionally *Dallia* may be classed as a separate "subfamily," Dalliini [sic].

8861. [BERG, L. S.] БЕРГ, Л. С. Черноморская килька. [The Black Sea sprat.] Доклады Академии Наук СССР., Сер. A. (*Compt. Rend. Acad. Sci. URSS., Sér. A*) 1931(5): 123-126. 1931.—Black Sea specimens of *Spratella sprattus phalerica* are compared with Atlantic and Adriatic specimens. If distinct from the latter form (natio *papalina*), they should be named natio *sulinae* (*Clupea salinae* Antipa). Contrary to Antipa's statement, they spawn in winter, not in summer.

8862. BREDER, C. M. Jr. Fish notes for 1929 and 1930 from Sandy Hook Bay. *Copeia* 1931(2): 39-40. 1931.—Records of 13 spp.

8863. CALDERWOOD, W. L. Notes on flying fish. *Scottish Nat.* 1931(190): 121-123. 1931.—*Exocoetus* in the Arabian Sea seems to vibrate its pectoral fins rapidly in taking off from the water, the tips of the fins beating the surface and leaving a pattern. After leaving the surface, it planes with these fins extended and stationary. The flight may extend for 150 yards. During flight some individuals touch the surface and take off again in the usual way.

8866. FIRTH, F. E. A note on spawning rosefish, Sebastes marinus (Linnaeus). *Copeia* 1931(2): 65. 1931.—Spawning recorded in Gulf of Maine in April—an early record.

8867. FRADE, F. L'anomalie faciale du thon rouge et son importance pour l'étude des migrations. *Bull. Soc. Portug. Sci. Nat.* 11(2): 7-10. 1930.—A certain anomaly, consisting of grooves on the side of the head, has been found among red tunnies on the Portuguese coast; in one instance the ratio of anomalies to normal specimens was 14 in 1000. Determination of the presence or absence of the same anomaly among Mediterranean specimens may shed light on the disputed question of migration of the sp. through the Strait of Gibraltar.

8868. FRASER-BRUNNER, A. Some interesting West African fishes, with descriptions of a new genus and two new species. *Ann. and Mag. Nat. Hist.* 8(45): 217-225. 4 fig. 1931.—Distributional and descriptive notes on 20 spp., chiefly from deep water off shore. *Centropomus ensiferus,* new to African waters (Nigeria); *Odontostomias micropogon,* figure of young; **LUCIOSUDIS** (p. 220) (Sudidae), near *Chlorophthalmus,* erected for *L. normani** (p. 220), lat. 11° 5′ S., long. 3° 20′ E.; *Diaphus fulgens** redescribed; *Lampanyctus* **fraseri*** (p. 224), lat. 3° 18′ S., long. 5° 17′ E. Types of new spp. in Brit. Mus.

8869. GREELEY, J. R. Fishes of the Lake Champlain watershed. (II of A biological survey of the Champlain watershed.) *Suppl. to 19th. Ann. Rept. New York Conserv. Dept.* 1929. p. 44-87. 16 col. pl. 1930.—This report presents data on the distribution, relative numbers, economic importance, and life histories of the local fishes. Of the 82 spp. and sspp. recorded, 38 (including 5 introduced) are classed as food or game fishes. Both angling and commercial fishing are extensive. Tables list the native and introduced species, and those found by the present survey. The distribution of many of the species is explained on the basis of post-glacial geology. The introduction of yellow perch, pike, and bass in certain Adirondack lakes has been detrimental to the native fish fauna. The author sounds a general warning against the introduction of non-native species, and at the same time against attempts to exterminate such native predatory species as the ling, gar, and bowfin, which help to preserve a balance in the fauna. A chart shows the distribution of species in 18 subdivisions of the Champlain drainage. The systematic account of 78 spp. includes notes on distribution, relative numbers, habits, spawning, food, and economic status, together with suggestions in regard to control, artificial planting, and legal regulations. There are colored plates of 16 species.

8870. HAMLYN-HARRIS, R. A further contribution to the breeding habits of Mogurnda (Mogurnda) adspersus Castelnau: the trout gudgeon. *Australian Zool.* 7(1): 55-58. 1931.—In captivity there appears to be but little variation in breeding habits. Stimulative feeding tends to hasten oviposition, and to increase the number of eggs laid. Oviposition does not take place, however, unless the ♂ is sufficiently energetic in his attentions, which take the form of a constant display of nuptial colouring, and, in addition, a tendency to "knead" the body of the ♀ with his mouth. The will and the ability to deposit 120-200 eggs at a time seems dependent upon such attentions since fertilization of the eggs does not take place until after they have been fastened upon a secure foundation. Each batch of eggs requires on an average 6 days to mature, and with few exceptions the individual eggs hatch nearly simultaneously. As soon as one batch is disposed of, "courting" commences almost immediately and proceeds normally until the next batch of eggs is laid. Comparatively few young fish survive in confinement, due to the cannibalistic tendencies of the ♀ and ♂.—*From author's summary.*

8871. HARDENBERG, J. D. F. The fishfauna of the Rokan mouth [Sumatra]. *Treubia* 13(1): 81-168. 1 chart. 1931.—This locality in the Strait of Malacca has become one of the most important fishery areas in the

world. The chief products are fish, shrimps, and the so-called trassy. The industry is in the hands of Chinese. The area, its tidal currents, and the composition of the water are described. Fishing is carried on by means of traps and drift-nets. Brief notes on the general fauna are followed by a systematic list of 149 fish spp., with notes on local distribution and abundance, ecological relations, habits, variation in size, and economic importance. The chief food of the local fishes is a crustacean, *Sergestes*. No definite evidence of over-fishing was found. A list of Chinese and Malayan names of fishes is appended.

8872. HERRE, ALBERT W. Notes upon Datnia plumbea, or Ayungin, a Philippine theraponid. *Copeia* 1930(3) : 76-77. 1930.—This sp. is redescribed. The type locality was probably Luzon, instead of Java.

8873. GHOSH, EKENDRANTH. Local names of some fish from the Teesta River. *Jour. Bombay Nat. Hist. Soc.* 34(2) : 586. 1930.—Scientific and the accompanying local or possibly trade names are given of 10 spp.—*Evermann & Clark.*

8874. HEINTZ, ANATOL. A reconstruction of Stenognathus gouldi (Newberry). *Ann. and Mag. Nat. Hist.* 8 (45) : 242-249. 5 fig. 1931.—Most of the plates of the head and body are figured from a specimen in the Brit. Mus. Several plates previously unrecognized are noted. Comparison is made with *Dinichthys*.

8875. HEWER, H. R. Studies in colour-changes in fish. Part V. The colour-patterns in certain flat-fish, and their relation to the environment. *Proc. Linnean Soc. London* 142. 73-75. 1929/30(1931).

8876. IHERING, RODOLPHO von. Cyprinodontes Brasileiros (Peixes "Guarús") systematica e informações biologicas. I. *Arch. Inst. Biol. Defesa Agric. e Animal* 4: 243-280. 4 pl., 20 fig. 1931.—A systematic revision of the 37 spp. of cyprinodont fishes of Brazil. Special attention is given to the characters of the gonopodium of the 13 viviparous genera. Five genera of oviparous Rivulidae are represented. Keys to Brazilian species are given for *Anableps*, *Poecilia*, and *Cynolebias*. Fifteen species are illustrated; special note should be made of the illustrations of *Poecilia vivipara**, *Lebistes reticulatus**, *Phalloceros caudimaculatus**. The systematic discussion is followed by general considerations on mosquito control by the smaller Brazilian fishes.

Nat.* [*Paris*] 1(2) : 134-139. 1 fig. 1929.—Of the 19 spp. here listed, 18 were collected in the upper Niger; 1, *Tilapia zilli,* from a lake in the Sahara. The systematic account consists chiefly of locality records and remarks on general distribution. The following are new to the Niger: *Gnathonemus stanleyanus; Nannocharax niloticus; Barbus anema; B. leonensis; Synodontis* augierasi* (p. 136), French Sudan, type in Paris Mus.

8885. [POPOV, A. M.] ПОПОВ, А. М. Тератологический материал по ихтиофауне Черного моря. [Teratological material from the ichthyofauna of the Black Sea.] [English summary.] Известия Академии Наук СССР., Отделение Физико-Математических Наук. (*Bull. Acad. Sci. URSS., Cl. Sci. Phys.-Math.*) 1930(10) : 1053-1078. 15 fig. 1930.—The following cases are described: shortening of the frontal bones and those of the lower jaw in *Liza aurata** and *Mugil cephalus*;* monstrosity of the lower jaw in *Anguilla anguilla*;* incurvation of the body in *Liza aurata* and *L. saliens*;* deformity or incomplete development of fins in *Raja clavata*, Bothus maeoticus*,* and *Crenilabrus ocellatus*;* general abnormalities in *Liza aurata** and *L. saliens;* and pseudoalbinism in *Scorpaena porcus*.

8886. POPOV, A. M. Einige Bemerkungen über die Variationen der Seitenlinien bei Hexagrammus stelleri Till. (Pisces, Hexagrammidae). *Zool. Anz.* 95(1/2) : 51-55. 5 fig. 1931.—The lateral lines* of *H. stelleri* are subject to such great variation that they can scarcely be used as taxonomic characters.

8887. ROULE, LOUIS, et LÉON BERTIN. Les poissons apodes appartenant au sous-ordre des Nemichthydiformes. *The Danish "Dana"-Expeditions 1920-22 in the north Atlantic and the Gulf of Panama.* 4. p. 1-113. 9 pl., 57 fig., incl. 6 distributional maps. Gyldendalske Boghandel: Copenhagen; Wheldon & Wesley: London, 1929.—The first part of this study is devoted to the systematics of the "Dana" collection. A comparative table is given of the 6 families and 12 genera recognized. There are diagnoses of 6 genera represented in this collection, including **AVOCETTINOPS** (p. 30), erected for *A. schmidti** (p. 30), Gulf of Mexico, 1000 m., and **PLATURONIDES** (p. 48), erected for *P. danae** (p. 48), off Bahamas, 600 m. The spp. of *Nemichthys* are reduced to a single one, *N. scolopaceus** Richardson (=*N. acanthonotus* Alcock, *N. fronto* Garman, *N. mediterraneus* Ariola), of which an emended description is given. *Avocettina* consists probably of a single sp., *A. infans** (Günther), of which an emended description is given. *Serrivomer sector** Garman, emended description; the previously described *S. beani* Gill & Ryder and *Nemichthys richardi* Vaill. are probably synonyms. *Cyema atrum** Günther, emended description. In general, the above-mentioned spp. live at considerable depths, most of them below 1000 m.; several are widely distributed in the 3 principal oceans; the peculiar beak probably functions as a net, not as an organ for seizing; the animals are probably rapid swimmers, taking rather large and active prey. The following new families are proposed, only the French form of the names being given: **AVOCETTINIDÉS** (p. 58), including *Avocettina* and *Labichthys;* **AVOCETTINOPSIDÉS** (p. 58), including *Avocettinops;* **GAVIALICIPITIDÉS** (p. 58), including *Gavialiceps;* and **SERRIVOMÉRIDÉS** (p. 59),

including *Serrivomer, Spinivomer, Platuronides,* and *Stemonidium*. For the foregoing 4 families, together with the Nemichthydidae and the Cyematidae (hitherto placed in the series Congroidei), the authors propose a new series, which they name **NEMICHTHYDEI** or **NEMICHTHYDIFORMES** (p. 57) (this group being called a suborder in the title of the paper). A key is given to the 12 genera of this group.—The second part deals with the ontogeny of *Nemichthys scolopaceus*. Larval forms which have been described under various names (*Leptocephalus canaricus* Lea, *L. andreae* Schmidt, *L. curvirostris** Strömman, *L. tiluroides** Strömman, *L. polymerus** Lea, *Tilurella gaussiana* Papp.) are reviewed and all are referred to *N. scolopaceus;* they represent 4 distinct phases in the larval development of this sp., which are here described in detail from the "Dana" collection. It is found that the total number of myotomes increases, during development, from about 300 to 500. There is a larval migration of the anus posteriorly, followed by a postlarval migration anteriorly. The smallest larvae are found in the western Atlantic, where spawning takes place in late winter or early spring; the larger larvae are found towards the coasts of Europe, Africa, and America, where they have been transported by ocean currents.—In the third part the ontogeny of *Cyema atrum* is described in detail; it has a remarkable leaf-shaped larva, which has been taken at considerable depths in various parts of the north Atlantic.—Extensive bibliography.

8888. SCHMIDT, P. A list of fishes of the Riu-Kiu Islands, collected by K. Awaya in 1929. Известия Академии Наук СССР., Отделение Физико-Математических Наук. (*Bull. Acad. Sci. URSS., Cl. Sci. Phys.-Math.*) 1930 (6) : 541-558. 1930.—Of 44 spp. collected, the following are new to the Riu-Kiu Isls.: *Atherina tsurugae, Epinephelus dispar, Lethrinus miniatus, Mulloides vanicolensis, Xystaema erythrourum, Leptoscarus viridescens, Callyodon mutabilis, Hepatus lincatus, Balistapus verrucosus, Monacanthus pardalis,* and *Ostracion cubicus*. The systematic account includes local names, synonymies, and descriptive and taxonomic notes.

8889. STROMER, E. Neues über die ältesten und primitivsten Wirbeltiere, besonders die Anaspida. *Sitzungsber. Math.-Naturwiss. Abt. Bayerischen Akad. Wiss.* 1930 (2) : 107-119. 1 fig. 1930.—Chiefly a critique of the work of recent authors, including Jaekel, Kiaer, Raymond, Sewertzoff, Simpson, Stensiö, and Stetson. The Anaspida are regarded as standing in close relationship to the recent Cyclostomata.

AMPHIBIA AND REPTILIA

G. K. NOBLE, *Editor,* Amphibia

KARL PATTERSON SCHMIDT, *Editor,* Reptilia

(See also in this issue Entries 6259, 7001, 7105, 8212, 8225, 8228, 8240, 8257, 8259, 8327, 8368, 8379, 8405, 8406, 9035, 9051, 9056, 9057)

GENERAL

8890. BARBOUR, T., and A. LOVERIDGE. Reptiles and amphibians from Liberia. In: The African Republic of Liberia and the Belgian Congo, based on the observations made and material collected during the Harvard African Expedition 1926-27. Vol. 2. (*Contr. Dept. Trop. Med. & Inst. Trop. Biol. & Med.* no. 5) Part 3. XXXV: *Herpetology.* p. 769-786. 3 pl. (1 col., 1 partly col.) Harvard Univ. Press: Cambridge, 1930.—This is a report on 33 Amphibia and 41 Reptilia collected by G. M. ALLEN and associates. Among the 33 spp. recorded from Liberia for the first time are, Reptilia: *Kinixys homeana, Riopa dura,* and *Naja goldii*. Amphibia: *Bufo togoensis,* 6 spp. of *Arthroleptis, Megalixalus immaculatus, Hyperolius puncticulatus**, and *Leptopelis bocagii*. The systematic accounts include field notes by Allen, distributional records, and taxonomic remarks. *Rana occipitalis* Günther (=*Ranosoma schereri* Ahl, *Rana mwanzae* Loveridge); *Rana* L. (=*Pseudoxenopus* Barbour & Loveridge); *Megalixalus fulvovittatus* (Cope) (=*M. vittiger* (Peters)). A list of 27 Liberian reptiles and amphibians not collected by the present expedition is appended; also a list of 1 *Bufo* and 10 Ranidae from Liberia identified in the collections of the U. S. Nat. Mus.; and a bibliography of 14 titles.

8891. BARBOUR, T., and A. LOVERIDGE. Reptiles and amphibians from the central African lake region. In: The African Republic of Liberia and the Belgian Congo, based on the observations made and material collected during the Harvard African Expedition 1926-27. Vol. 2. (*Contr. Dept. Trop. Med. & Inst. Trop. Biol. & Med.* no. 5) Part 3. XXXV: *Herpetology.* p. 786-796. Harvard Univ. Press: Cambridge, 1930.—This is a report on 25 Reptilia and 13 Amphibia collected chiefly in the Lake Kivu region (Belgian Congo and Uganda). The systematic account includes distributional records, taxonomic remarks, and notes on food. *Chamaeleon johnstoni* Boulenger (=*C. graueri* Steindachner, *C. johnstoni affinis* Sternfeld, *C. ituriensis* Schmidt); *Rana fuscigula* and *Cacosternum boettgeri,* new to Uganda.

8892. DYMOND, J. R. The amphibians and reptiles of the Lake Abitibi region [Ontario]. *Univ. Toronto Studies Biol. Ser.* 32. 35-36. 1928.—An annotated list of 7 spp. (1 *Bufo,* 1 *Hyla,* 4 *Rana,* and 1 *Thamnophis*). An unusual red phase of *Thamnophis sirtalis* is described.

8893. KLINGELHÖFFER, W. Terrarienkunde. 575p. 17 pl. (6 col.), 560 fig. Julius G. G. Wegner: Stuttgart, 1931. Pr. 29.40 M.—The first 68 pages treat of the construction of terraria, their heating, fitting, and stocking. Detailed plans for construction are given, with full descriptions. Then follow extended sections on the terrarium management of lizards, crocodilians, turtles, snakes, and amphibia. The various species of each group which can be kept in confinement are described in detail, with full accounts of their habits; breeding habits are given for a large number of species. The work is valuable not only for its instructions as to the handling of the animals, but also for information regarding the natural history of a large number of European, Asiatic, African, and American species of reptiles and amphibia. Photographs and drawings accompany the descriptions of species. Some anatomical drawings and description introduce each order. Much material is supplied of value to beginners in the systematic study of the orders.—*L. E. Griffin.*

8894. LOGIER, E. B. S. A faunal investigation of King Township, York County, Ontario. IV. The amphibians and reptiles of King Township. *Trans. Roy. Canadian Inst.* 17 (2) : 203-208. 1930.—An account of 13 amphibians, 6 snakes, and 2 turtles, with notes on habitats, seasonal occurrence, and breeding habits. The eggs, larvae, and vocal activity of some of the amphibians are discussed.

AMPHIBIA

8895. AHL, ERNST. Zur Systematik der afrikanischen Arten der Baumfroschgattung Hyperolius (Amph. Anur.). *Mitteil. Zool. Mus. Berlin* 17 (1) : 1-132. 1931.—This paper is based upon the rich material of the Berlin Mus., and consists chiefly of a key and descriptions of new spp. Nearly all of the spp. were investigated osteologically. A more comprehensive treatment in a forthcoming monograph of the "Tierreich" is announced. *H.* **stenodactylus** (p. 21), Cameroon; *H.* **angolanus** (*Rappia platyceps* v. *angolensis* Ferreira, preoccupied) (p. 22);

H. **pygmaeus** (p. 22), Tanganyika Terr.; *H.* **petersi** (p. 23), Kenya; *H.* **vermicularis** (*Rappia vermiculata* Pfeffer, preoc.) (p. 24); *H.* **multifasciatus** (p. 24), Tanganyika Terr.; *H.* **brevipalmatus** (p. 25), Cameroon; *H.* **kivuensis** (p. 26), Lake Kivu; *H.* **bituberculatus** (p. 27), Belgian Congo; *H.* **acuticeps** (p. 29), Tanganyika Terr.; *H.* **guineensis** (p. 30), "Guinea"; *H.* **castaneus** (p. 31), NE. of Lake Kivu; *H.* **scriptus** (p. 32) and *H.* **albolabris** (p. 33), Tanganyika Terr.; *H.* **baumanni** (p. 34), Togo; *H.* **raveni** (p. 36), NE. of Lake Kivu; *H.* **ademetzi** (p. 37), Cameroon; *H.* **kwidjwiensis** (p. 38), Belgian Congo; *H.* **variabilis** (p. 39), Tanganyika Terr. (type) and Belgian Congo; *H.* **punctatissimus** (p. 41), E. Africa; *H.* **ipianae** (p. 43), "Ipiana"; *H.* **pictus** (p. 44), Tanganyika Terr. (type) and Kenya; *H.* **tornieri** (p. 45), Tanganyika Terr.; *H.* **simus** (p. 46), Belgian Congo; *H.* **pulcher** (p. 48), Cameroon; *H.* **asper** (p. 49), Kenya; *H.* **moseri** (p. 50), Togo; *H.* **oeseri** (p. 51), Liberia; *H. pincturatus*, description of tadpole; *H.* **albofrenatus** (p. 53), Tanganyika Terr.; *H.* **breviceps** (p. 54), Portuguese East Africa (type) and Kenya; *H. parallelus*, description of tadpole; *H.* **buchholzi** (p. 56), Gold Coast; *H.* **guttolineatus** (p. 57), *H.* **bitaeniatus** (p. 58) and *H.* **ngoriensis** (p. 60), Tanganyika Terr.; *H.* **depressus** (p. 61), Togo; *H.* **kandti** (p. 62), Lake Kivu; *H.* **schubotzi** (p. 63), Belgian Congo; *H.* **hildebrandti** (p. 64), Cameroon; *H.* **latifrons** (p. 65), Belgian Congo; *H.* **nyassae** (p. 66), Tanganyika Terr. (type) to Transvaal; *H.* **melanophthalmus** (p. 68), Zanzibar; *H.* **laticeps** (p. 69), Togo; *H.* **wettsteini** (p. 70), *H.* **phrynoderma** (p. 71) and *H.* **argentovittis** (p. 72), Tanganyika Terr.; *H.* **bergeri** (p. 73), Kenya; *H.* **karissimbiensis** (p. 74), Belgian Congo; *H.* **fuelleborni** (p. 75), Tanganyika Terr.; *H.* **coeruleopunctatus** (p. 76), Kenya; *H.* **marungaensis** (p. 77), Angola; *H.* **decoratus** (p. 78), Cameroon (type) and Angola; *H.* **microstictus** (p. 80), Cameroon; *H.* **albifrons** (p. 81), Africa; *H.* **rugegensis** (p. 82), "Rugege-Wald"; *H.* **argentophthalmus** (p. 83), locality unknown; *H.* **substriatus** (p. 84), Tanganyika Terr.; *H.* **mohasicus** (p. 85), Belgian Congo; *H.* **brachiofasciatus** (p. 87), French Equatorial Africa; *H.* **rubripes** (p. 88), "Kililana"; *H.* **discodactylus** (p. 89), "Rugege-Wald" (type) and west of Lake Edward; *H.* **obstetricans** (p. 90), life history, Cameroon; *H.* **maximus** (p. 91), British Cameroon (type) and "Guinea"; *H.* **pulchromarmoratus** (p. 92), Kenya; *H.* **multicolor** (p. 94), Belgian Congo; *H.* **macrodactylus** (p. 95), Lake Kivu; *H.* **flavoguttatus** (p. 96), Tanganyika Terr. (type) and Kenya; *H.* **udjidjiensis** (p. 97), Tanganyika Terr. (type) and Kenya; *H.* **thoracotuberculatus** (p. 98), Africa; *H.* **callichromus** (p. 99), Belgian Congo (type) and Tanganyika Terr.; *H.* **houyi** (p. 101), Tanganyika Terr.; *H.* **monticola** (p. 102), Ruanda; *H.* **oculatus** (p. 103), "Duki-Ufer und Golei-See"; *H.* **nigropalmatus** (p. 104), Cameroon; *H.* **rosaceus** (p. 105), Togo; *H.* **alticola** (p 106), Uganda; *H.* **ventrimaculatus** (p. 107), NE. of Lake Kivu; *H.* **dermatus** (p. 108), Portuguese E. Africa; *H.* **narinus** (p. 109), tadpole described, Togo; *H.* **scheffleri** (p. 111), Kenya; *H.* **togoensis** (p. 113), Togo; *H.* **stuhlmanni** (p. 113) and *H.* **irregularis** (p. 114), Belgian Congo; *H.* **renschi** (p. 115), Zanzibar; *H.* **adolphi-friederici** (p. 116), "Rugege-Wald"; *H.* **noblei** (p. 118), Tanganyika Terr.; *H.* **trifasciatus** (p. 119), Liberia; *H.* **decipiens** (p. 120), Belgian Congo; *H.* **koehli** (p. 121), Tanganyika Terr.; *H.* **unicolor** (p. 122), "Ipiana"; *H.* **spatzi** (p. 123), Senegal; *H.* **chabanaudi** (p. 124), French Equatorial Africa; *H.* **gularis** (p. 125), Angola; *H.* **hieroglyphicus** (p. 126), Cameroon; *H.* **quadratomaculatus** (p. 127) and *H.* **goetzei** (p. 128), Tanganyika Terr.; *H.* **bicolor** (p. 129), Angola; *H.* **acuticephalus** (p. 131), French Equatorial Africa; *H.* **graueri** (p. 131), Belgian Congo. Types in Berlin Mus.

8896. ANGEL, F. Sur une espèce nouvelle de grénouille du Tonkin, appartenant au genre Rana. *Bull. Mus. Nation. Hist. Nat. Paris* 1928(5): 319-320. 1928.—*Rana* (*Rana*) **delacouri** (p. 319), type in Paris Mus.

8897. CANNELLIER, PIERRE Le. Triton marbré. *Bull. Soc. Linn. Normandie* 1: 91. 1928(1929).—A record on *Molge marmorata.*

8898. FLORESCO, N. Locomotion de la grénouille. *Bul. Fac. Stiinte Cernauti* 3(1/2): 248-257. 1929.—The flat form of the frog acts like a plane on the surface of the water. The skin by its integrity and humidity preserves the general condition of the animal. The hind legs function for swimming and jumping; the fore legs for balancing and horizontal movement.—*N. Floresco* (*transl. by A. M. Boring*).

8899. GAIGE, HELEN T. Notes on Syrrhophus marnockii Cope. *Copeia* 1931(2): 63. 1931.—Range of this sp. extended to the Big Bend region of Texas. Notes on habits and voice are given.

8900. GRANT, CHAPMAN. A new frog from Porto Rico. *Copeia* 1931(2): 55-56. 1 fig. 1931.—*Eleutherodactylus* **karlschmidti*** (p. 55), type in author's coll.

8901. GRANT, CHAPMAN. Notes on Bufo marinus (Linnaeus). *Copeia* 1931(2): 62. 1931.—This introduced sp. has increased both on the coast and inland in Porto Rico. Notes on color, measurements, and habits are given.

8902. HORIKAWA, YASUITI. A list of frogs from Formosa. *Trans. Nat. Hist. Soc. Formosa* 21(114): 139-145. 1931.—25 spp. are listed.

8903. [KARPINSKII, A. P.] КАРПИНСКИЙ, А. П. О проблематическом ископаемом из палеозойских слоев Северного Урала. [A problematical fossil from the Paleozoic of the northern Urals.] Доклады Академии Наук СССР., Сер. A. (*Compt. Rend. Acad. Sci. URSS., Sér. A.*) 1930(15): 387-390. 1930.—Two scale-like fossils from the Lr. Carboniferous or Up. Devonian are believed to be related to the early amphibians, and the name *Proamphibia problematica* is suggested for them.

8904. MYERS, GEORGE S. Ascaphus truei in Humboldt County, California, with a note on the habits of the tadpole. *Copeia* 1931(2): 56-57. 1931.

8905. PARKER, H. W. Some brevicipitid frogs from Tanganyika Territory. *Ann. and Mag. Nat. Hist.* 8(45): 261-264. 1931.—**PROBREVICEPS** (p. 262) (Brevicipitidae), near *Spelaeophryne*, type *P.* **macrodactylus** (*Breviceps m.* Nieden=*B. usambaricus* Barbour & Loveridge) (p. 262); *P. m.* **loveridgei** (p. 263), Tanganyika Terr., type in Brit. Mus.; *P.* **uluguruensis** (*Breviceps u.* Loveridge) (p. 264).

8906. SLATER, JAMES R. The mating of Ascaphus truei Stejneger. *Copeia* 1931(2): 62-63. 1931.—Observation in State of Washington.

8907. TRAUTMAN, MILTON B. Another record of Scaphiopus holbrookii for Virginia. *Copeia* 1931(2): 63. 1931.

8908. WOLTERSTORFF, W. Über fossile Frösche aus der Papierkohle von Burgbrohl (Laacher See). *Jahrb. Preuss. Geol. Landesanst.* 49(2): 918-932. 2 pl., 4 fig. 1928(1929).—Lower Miocene, *Palaeobatrachus* cf. *diluvianus.* 29 specimens are described, ranging from adults to unmetamorphosed larvae. Notes are given on the systematics and biology of the genus.—*A. S. Romer.*

REPTILIA

8909. BURT, CHARLES E. The status of the spotted race-runner, Cnemidophorus sexlineatus gularis (Baird and Girard.). *Proc. Biol. Soc. Washington* 44: 73-78. 1931.—*Cnemidophorus sexlineatus sackii* (Wiegmann) (=*C. gularis* B. & G.).

8910. COOK, LORENZO H. Notes on an Arizona elegans occidentalis Blanchard. *Copeia* 1930(4): 158. 1930.—A specimen collected in California fed on lizards and mice in captivity.

8911. COTTE, J. Indigénat de la Tortue grecque en Provence. *Ann. Mus. Hist. Nat. Marseille* 22(4): 83-93. 7 fig. 1930.—The present distribution of *T. graeca* in Var and Bouches-du-Rhône and also fossil indicate that it is endemic, rather than intro

man. The marked variation in the plates of *T. graeca* and *T. ibera* and the tendency toward intergradation of their characters are discussed. If one regards them as 2 subspp. becoming more distinct, one may "create for them a conventional sp., called *Testudo* tyrrhenica" (p. 93), for which either *T. graeca* or *T. ibera* is suggested as "type."

8912. **ESTIVAL, G. Un cas de morsure par Cerastes vipera L.** *Arch. Inst. Pasteur Algérie* 7(2): 220-221. 1929.—Probably the first published case of poisoning by *C. vipera*, at least for northern Africa.

8913. **FLOWER, STANLEY S. The occurrence of the "black-and-white cobra," Naja melanoleuca, in the Sudan.** *Ann. and Mag. Hist.* 7(41): 499-500. 1931.

8914. **GERTSCH, WILLIS J., and LOWELL A. WOODBURY. Spiders found in the stomachs of Sceloporus graciosus graciosus (B. & G.) (Araneina).** *Ent. News* 41(10): 318. 1930.—A list of 7 species eaten by this lizard in Utah.

8915. **H[ERKLOTS], G. A. C. Varanus albigularis.** *Hong Kong Naturalist* 1(4): 193. 1930.—A *Varanus* previously reported from Hong Kong (*Ibid.* 1(2): 76-78. 1930) proves to be *V. albigularis*, evidently imported from Africa.

8916. **JENYNS, SOAME. The tortoise and the turtle in Kwongtung.** *Hong Kong Naturalist* 1(4): 161-163. 1930.—Chiefly history and folk-lore.

8917. **ROULE, LOUIS. Les lézards géants de l'époque actuelle.** *Rev. Gén. Sci. Pures et Appl.* 42(10): 295-296. 1931.

8918. **SMEDLEY, NORMAN. Ovoviviparity in sea-snakes.** *Nature [London]* 127(3192): 13. 1931.—There is no evidence to show whether the Hydrophiinae are viviparous or ovoviviparous. Both conditions are found in the Laticaudinae, perhaps within a single sp.

8919. **STEINHEIL, FRITZ. Die europäischen Schlangen; Kupferdrucktafeln nach Photographien der lebenden Tiere.** 9. pl. 41-45. Gustav Fischer: Jena, 1931. —The species figured are *Vipera ammodytes ammodytes*, *V. a. transcaucasiana*, and *Tropidonotus natrix persa*.

8920. **WITTE, GASTON FR. de. Description d'un Vipéride nouveau du Kivu (Atractaspis schoutedeni sp. n.).** *Rev. Zool. et Bot. Africaines* 19(2): 224-225. 3 fig. 1930.—Type in Congo Mus.

LUDLOW GRISCOM, *Editor*

(See also in this issue section Economic Ornithology; and Entries 6098, 6101, 6257, 6259, 6838, 7393, 8413, 8509, 8510, 9035, 9051, 9056, 9057)

GENERAL OR POPULAR

8921. **ALLEN, A. A., L. A. FUERTES, and M. D. PIRNIE. General ornithology laboratory notebook for the recording of observations made in the field and studies made in the laboratory on the birds of Eastern North America.** illus. Comstock Publishing Co.: Ithaca, N. Y. [1930] Pr. $4.

8922. **ALLEN, ARTHUR A. The book of bird life. A study of birds in their native haunts; with photographs by the author.** xix+426p. 1 col. pl., 275 fig. D. Van Nostrand Co., Inc.: New York. 1930.—This book is a guide to bird habits rather than an identification manual; it outlines the principles of ornithology and suggests methods of study. Part I deals with history, classification, distribution, ecology, migration, courtship, home life, plumage, and economic relations. There is a special discussion of the balance of nature and the conservation of wild life. Part II deals with methods of study, field trips, keeping of records, banding, methods of attracting birds, nests, photography, songs, birds as pets, and an outline for intensive study of a species. Much of the material has already appeared in the School Department of Bird-Lore. The book is profusely illustrated with photographs of wild birds by the author. At the end of each chapter are references to suggested reading.

8923. **CLARKE, HARRY. Birds killed by automobiles.** *Bird-Lore* 32(4): 271. 1930.—More than 1 dead bird per mile was found along Iowa roads. Red-headed woodpeckers were chief sufferers.

8924. **COLE, SANFORD D. Oil pollution.** *Royal Soc. Protect. Birds Ann. Rept.* 39: 37-40. 1929.—An address on the killing of birds by oil pollution of the sea and on preventive measures.

8925. **CORSAN, G. H. The W. K. Kellog bird sanctuary.** *Aviculture [Chicago]* 2(9): 216-219. 2 pl. 1930.

8926. **CRANDALL, LEE S. Three very rare Amazons.** *Aviculture [Chicago]* 2(9): 211-213. 1 col. pl. 1930.—Notes on the following 3 parrots: *Amazona imperialis**, *A. guildingi**, and *A. versicolor**.

8927. **DROST, RUDOLF. XI. Bericht der Vogelwarte der Staatl. Biologischen Anstalt Helgoland (1926-1928). [Eleventh report of the bird observatory of the State Biological Institution of Helgoland.]** *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung* 1(1): 2-13. 1930. —An account of the activities of this observatory. In the past 20 years the observatory and its collaborators have banded 102,095 birds belonging to 228 species, from which there have been 2119 return records.

8928. **DROST, R. Aufruf zur Schaffung eines internationalen Stationsnetzes zur Beobachtung des Vogelzuges an allen Küsten der Nordsee. [Call for the organization of an international chain of stations for the observation of bird migration on the coasts of the North Sea.]** *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung* 1(1): 43-45. 1930.

8929. **DROST, [R.]. Rückmeldung eines deutschen Rotrückigen Würgers (Lanius c. collurio L.) aus Aegypten. [Return record of a German red-backed shrike in Egypt.]** *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung* 1(1): 47-48. 1930.

8930. **DROST, RUDOLF. Zum Zug deutscher Stelzen (Motacilla L.).** *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung.* 1(2): 86-88. Map. 1930.—Young birds of *Motacilla f. flava*, *M. c. cinerea*, and *M. a. alba*, banded in Germany, have been recovered in the fall in southwestern France. One record of *M. a. alba* indicates that it winters in Spain.

8931. **FEHRINGER. Die Vogelwarte Rappenwört, Karlsruhe (Baden).** *Ornithol. Monatsschr.* 55(2): 24-29. 1930.—The author discusses the steady decrease in bird life and human shortsightedness in judging birds on a merely utilitarian basis. As a means of public education on this subject, the city of Karlsruhe has established a bird observatory. Courses of instruction, economic investigations, and studies of migration are planned. Living birds are kept for observation.

8933. **GLEGG, WILLIAM E. A correction.** *Ibis* 6(2): 379. 1930.—Letter correcting a notice of his paper "The Thames as a bird-migration route" in the *Ibis* for Jan., 1930.—*W. W. Bowen.*

8934. **GREY of FALLODON. The habits and breeding of mandarin and North-American (Carolina) wood ducks.** *Nat. Hist. Mag. [London]* 2(16): 249-257. 5 fig. 1930.—Observations on protected and semidomesticated birds in England. The 2 spp. resemble each other in plumage and habits, but not in voice, and do not seem to hybridize. The mandarin* is a more alert, enterprising, and vital sp. than the wood duck*.

8935. **GROTE, H. Ueber den gegenwärtigen Stand der Vogelberingung in Russland.** *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung* 1(1): 40-43. 1930.—In late years 78,000 birds have been banded in Russia, from which there have been 295 recoveries of 38 species. Many

of them had wandered to foreign countries, including 5 *Corvus frugilegus* taken in Germany and France, 1 *Nycticorax nycticorax* in central Africa, 1 *Dafila acuta* in Egypt, and 2 *Larus argentatus* in Denmark and Norway.

8936. **HADLEY, ALDEN H. Oil pollution and sea-bird fatalities.** *Bird-Lore* 32(3): 241-243. 2 fig. 1930.—Great numbers of sea birds along the Massachusetts coast are killed by oil wastes on the water.

8937. **HENNINGS, H. Aus der Arbeit Vogelberingung.** *Aus der Heimat* 43(5): 155-156. 1930.—Recoveries of birds banded along the lower Elbe, Germany, are as follows: stork, in Poland, lapwings, in Portugal, Spain, France, and Italy; hen harriers, in Belgium, France, and Portugal. A swallow returned to the same nest for three years. A hen harrier and several lapwings have been observed in subsequent years in the area where originally banded.

8938. **HOFFMAN, E. C. Weighings of the northern form of the eastern song sparrow.** *Bird-Banding* 1(2): 80-81. 1930.—Late fall and early spring migrants in Ohio weigh more than the resident birds of this sp.

8939. **INGRAM, GEOFFREY C. S., and H. MORREY SALMON. Storm-driven birds in South Wales, December 1929.** *British Birds* 23(10): 276-277. 1930.—Records of numbers of sea birds that had succumbed to storm.

8940. **KIP, HERBERT Z. Concealment as a factor in nest-building.** *Bird-Lore* 32(3): 181-184. 1930.—That birds carefully and deliberately conceal their nests is, in the author's opinion, a myth.

8941. **KNORR, B. Auffälligkeiten am Kranichzug.** *Ornithol. Monatsschr.* 55(6): 81-83. 1930.—Sudden disorder in migrating flocks of cranes is discussed. Altered appearance of a familiar landscape, and search for the regular line of flight after straying, are among the causes suggested.

8942. **LANGE, HALFDAN. Bestemmelse af flyvende Fugle. [Identification of birds in flight.]** *Flora og Fauna [Copenhagen]* 1929(2): 41-62. 42 fig. 1929.—A key is given for part of the birds of Denmark, as a means of identifying birds in flight. Small birds and rare birds are not included.

8943. **LA TOUCHE, J. D. D. A handbook of the birds of Eastern China (Chihli, Shantung, Kiangsu, Anhwei, Kiangsi, Chekiang, Fohkien, and Kwangtung Provinces). Part V. (Containing families Motacillidae, Alaudidae, Zosteropidae, Nectariniidae, Dicaeidae, Pittidae, and Eurylaimidae.)** 1(5): xx+399-500. 2 pl. Taylor & Francis: London, 1930.—Part V concludes vol. I and the account of the Passeres. This volume includes 378 birds of 31 families from eastern China. The accounts of the various forms include English common names, synonymy, description, distribution, and notes on taxonomy, migration, and habits. Corrigenda and addenda and a systematic as well as an alphabetical index are supplied.

8944. **LONGSTREET, R. J. Chimney swift banding experiences in Florida.** *Florida Nat.* 3(4): 100-104. 1930.

8945. **MADSEN, HARRY. Quelques remarques sur la cause pourquoi les grands oiseaux au Soudan planent si haut au milieu de la journée.** *Vidensk. Meddel. Dansk Naturhist. For. København* 88: 301-303. 1929/1930.—At Timbuktu, in summer, the temp. from 11 a. m. to 4 p. m. rises to about 35-45° C. Small birds then remain in the shade. Large birds, such as *Milvus migrans parasiticus, Necrosyrtes monachus monachus, Corvus scapulatus,* and *Abdimia abdimii,* escape the strong radiation from the superheated ground by soaring at an estimated altitude of 700-1000 m. At 1000 m. the temp. is almost constant, and equal to that on the ground at sunrise.

8946. **MATHEWS, GREGORY M. Note on the dates of issue of the parts of G. R. Gray's "Birds" in the zoology of the voyage of H. M. S. "Erebus" and "Terror" during the years 1839 to 1843, and other bibliographical remarks.** *Ibis* 6(1): 120-123. 1930.

8947. **MICHAEL, ENID. Bird intelligence.** *Yosemite Nature Notes* 9(7): 69-70. 1930.—Note on blue-fronted jays.

8948. **MOREAU, R. E. On the age of some races of birds.** *Ibis* 6(2): 229-239. 1930.—For the purpose of this discussion "races" are assumed to be of genetical significance. On different lines of argument it appears that 2 races, *Galerida cristata nigricans* and *Columba livia dakhlae,* have developed in the last 10,000 years. *Galerida cristata brachyura* and *Prinia gracilis natronensis* have probably differentiated in less than 5000 yrs. The fact that no Passerine races have developed in Mesopotamia may indicate that the lower figure, namely 5000 yrs., is not far from the minimum required for the development of an ornithological race.—*From author's summary.*

8949. **NAUNDORFF, ELISABETH. Über einsichtiges Verhalten, Gemütsleben und Abrichtung einer Dohle.** *Zool. Garten [Leipzig]* 2(10/12): 299-303. 1930.—This captive jackdaw could speak a few words and tried to mimic every noise. It became tame under careful handling. It was trained to find hidden food and to do various tricks. Eventually it was allowed to fly in the open, and returned only at the sight or the call of the author. It was jealous and flew in the face of persons it disliked. It was frightened by a stuffed kite. It died, during a brief absence of the author, without visible cause.

8950. **NICE, MARGARET MORSE. Do birds usually change mates for the second brood?** *Bird-Banding* 1(2): 70-72. 1930.—Data assembled on 12 spp. of Passeres show that 7 pairs of 3 spp. changed mates in one season, while 20 pairs of 11 spp. did not. There is ordinarily no change of mates within a season when the 2 nesting cycles overlap. There is more apt to be a change when there is a longer interval between the 1st and 2nd broods.

8951. **PETERS, NICOLAUS. Über eine Hornbildung beim Jagdfasan.** *Zool. Anz.* 88(7/8): 221-223. 1 fig. 1930.—A pheasant in Germany was found with a hornlike process firmly attached to the basal part of the mandible. This malformation may have had its origin in an earlier fracture of the mandible.

8952. **REBOUSSIN, ROGER, with descriptions by J. RAPINE. L'oiseau chez lui. Livre couleur du temps.** (Continuation.) Fasc. 7. p. 49-54. 1 col. pl., 11 crayon sketches; Fasc. 8. p. 57-64. 1 col. pl., 9 crayon sketches; Fasc. 9. p. 65-72. 1 col. pl., 12 crayon sketches. Les Presses Universitaires de France: Paris, 1930.—Fasc. 7. Illustrations and descriptions are given of the following: Limicolae, Charadriidae: *Numenius arquata arquata* (L.), *Limosa l. lapponica* (L.), *Philomachus pugnax* (L.), *Charadrius hiaticula hiaticula* L., Passeres, Motacillidae: *Anthus spinoletta petrosus* (Montagu.). Fasc. 7 is concluded with a general discussion of dunes and their bird fauna. Fasc. 8. Laridae: *Sterna a. albifrons* Pallas. Charadriidae: *Charadrius apricarius altifrons* Brehm; *C. a. alexandrinus* L. Anatidae: *Tadorna tadorna* (L.). Motacillidae: *Anthus pratensis* (L.). Fasc. 8 is concluded with a general discussion of steppes and lagoons with their bird fauna. Fasc. 9 contains a general discussion of lagoons and their bird fauna.

8953. **SALZMANN, WALTER. Ardea p. purpurea L. in Hessen-Nassau.** *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung* 1(1): 46. 1930.—A young bird, banded in Holland in June, 1929, was captured the following Sept. in Germany.

8954. **SCHÜZ, E. Aufgaben der Vogelzugsforschung.** *Aus der Heimat* 43(5): 134-138. 2 map, 3 fig. 1930.—A discussion of bird-banding and other ways of studying migration in Germany.

8955. **SCHÜZ, E. Vom Zug des Blässhuhns, Fulica atra L., an Hand der Beringungsergebnisse.** *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung* 1(1): 14-20. Map. 1930.—Fifty-two return records for the coot are detailed. In Britain, Switzerland, and Hungary the species seems largely non-migratory, but in north central Europe the migratory instinct is well marked. Birds nesting in Sweden winter in Spain and Austria; those of eastern and northern Germany winter in Austria, Switzerland, Netherlands, and northern France; those of Hungary go in part to Italy. The longest migration ascertained is from Sweden to Spain (2400 km.). Ap-

parently the species migrates to escape the cold. In certain cases the daily average distance covered in migration has ranged from 185 to 262 km. Some birds may fly over the Alps and the Sudetic Mts. In winter the coots often gather in great flocks on open water, especially near cities, where they are fed. The greatest age ascertained for a banded bird is 9 years, 1 month.

8956. SCHÜZ, E. Woher kommen unsere Winter-Saatkrähen? *Naturforscher* [*Berlin*] 7(1): 13-16. Map, 2 fig. 1930.—Returns from banded individuals of *Corvus frugilegus* show that breeding birds of central Russia winter in Germany and France, while those of England and France migrate comparatively short distances.

8957. STENHOUSE, J. H. Birds of historic interest in the Royal Scottish Museum. III. Birds of Franklin's overland expeditions. *Scottish Naturalist* 1930(183): 75-84. 1930.—Of about 80 spp. brought back by Richardson from the first expedition (1819-22), 40 specimens were presented to the Mus. of the Univ. of Edinburgh in 1823. Of these, only 2 specimens of *Pediocaetes* [sic] *p. phasianellus* are still extant. From the second expedition (1825-1827) about 325 birds were brought back, of which 58 are extant. A list of these is given. Included are type specimens of *Pyrgita* (*Pipilo*) *arctica* Swainson, *Picus* (*Apternus*) *arcticus* Swainson, *Tetrao* (*Lagopus*) *leucurus* Swainson & Richardson, *Larus franklinii* Richardson. The museum also contains probably the type specimen of *Tetrao franklinii* Douglas.

8958. STENHOUSE, J. H. Birds of historic interest in the Royal Scottish Museum. IV. Birds collected by Captain Sturt in 1830, on the "Banks of the River Murray." *Scottish Nat.* 1930(184): 101-104. 1930.—At least 9 of the original 18 birds sent from Australia are still extant, among them the type of *Ibis spinicollis* Jameson.

8959. STEVENS, O. A. Some secondary results of bird-banding. *Bird-Banding* 1(2): 67-69. 1930.—Data on banded birds (chiefly Harris's and White-throated Sparrows) in N. Dakota indicate a large number of repeat records on the day before a departing flight. Early migration records are secured better by trapping than by field observation.

8960. [TUGARINOV, A. Ya.] ТУГАРИНОВ, А. Я. Миграции птиц северной Азии. [Migration of birds of northern Asia.] Природа (Priroda [*Leningrad*]) 1930 (5): 507-543. 6 maps. 1930.—Based on literature and the author's personal observations, bird migration of the region cited is discussed. A list is given of the birds according to their migration routes. These routes are as follows: (1) Birds crossing the continent in various way; (a) in a general southerly direction; (b) converging from the entire northern width of the continent toward the Khingan Mts.; (c) passing through Turkestan to India, Afghanistan, Persia, Arabia, and Africa (this route is followed by the great majority of Asiatic birds); (d) passing to Arabia and western India, by a small group of central Asiatic birds. (2) Birds, frequently not ecologically related to the water, following sea shores in one of the following ways; (a) along the Arctic coast westward and southward to the Atlantic coast of Europe; (b) along the Asiatic coast of the Pacific; (c) along the American coast of the Pacific by way of Bering Sea. (3) A small group of birds not following the same route in spring and fall migrations, passing in spring from the coast of Japan across the Amur region to Yakutsk, in the fall going east to Bering Sea and along the coast to Japan.

8961. VÄLIKANGAS, ILMARI. Phänologische Beobachtungen über Raubvögel mit Hilfe eines Uhus. [Phenological observations on birds of prey with the aid of an eagle owl.] *Ann. Soc. Zool.-Bot. Fennicae, Vanamo* 8: (25)-(28). 1929.—Migration data on various species of hawks in Finland, based on individuals shot while attacking an eagle owl (either stuffed or captive).

8962. WENDEHORST. Erfolgreicher Säbelschnäblerschutz an der Nordseeküste. *Ornithol. Monatsschr.* 55 (6): 95-96. 1930.—These colonies of avocets are now protected.

8963. WITHERBY, H. F. The "British Birds" marking scheme. Progress for 1929. *British Birds* 23(10): 258-265. 1930.—Over 25,000 British birds were ringed in 1929, making a total of 258,791 for the period 1909-1929. A number of return records from various parts of Europe and Africa are mentioned.

8964. ANONYMOUS. Banded herring gull found with beak fastened shut. *Bird-Lore* 32(3): 250. 1930.—A bird banded in Maine found in Florida.

SYSTEMATICS

8965. BAKER, E. C. STUART. [Changes in nomenclature.] *Bull. British Ornith. Club* 50(342): 79. 1930.—*Muscicapella* Bianchi (=*Briania* Chasen & Kloss). *Chalcoparia singalensis rubinigentis* Baker (=*C. s. assamensis* Kloss).

8966. BOYD, A. W. Melanic nestlings of the lapwing. *British Birds* 24(4): 109. 1930.—Two out of 4 downy young *Vanellus vanellus* in Cheshire were melanic.

LIFE HISTORY

8967. BENTHAM, HOWARD. Black-throated diver in Surrey. *British Birds* 23(10): 277-278. 1930.—A *Colymbus arcticus* was seen to dive and emerge beneath a great crested grebe, besides attacking it otherwise.

8968. BOOTH, H. B. Night soaring of swifts. *British Birds* 24(4): 111. 1930.—*Apus a. apus*, after high vesper flights, returns to its roosting quarters.

8969. BRAUN, RUDI. Beiträge zur Biologie der Vögel von Angola. *Jour. Ornith.* [*Berlin*] 78(1): 47-49. 1930.—Notes on breeding and other habits of 11 spp.

8970. BROWN, R. H. Fledging-period of the barn-owl. *British Birds* 23(10): 274-275. 1930.—This period lasted from 64 to 68 days for *Tyto a. alba* in a case observed in Cumberland.

8971. BUTLER, A. L. Pigeons alighting on water to drink. *Ibis* 6(2): 383-384. 1930.—Between Senj and Fiume on the Adriatic coast the limestone rock falls abruptly to the sea; the water-shed is on the inland side of the range, and on the seaward side there is little or no fresh water excepting that which percolates through the sand at the foot of the range and bubbles up in numerous springs 30-50 yards out to sea. Pigeons regularly alight and drink, when the tides are fairly low, on these fresh-water areas in the sea.—*W. W. Bowen.*

8972. CHAFFER, NORMAN. The cicada bird. (Edoliisoma tenuirostre.) *Australian Zoologist* 6(3): 203-204. 1 pl. 1930.—Account of song and nesting.

8973. COLLENETTE, C. L. Hawfinch [Coccothraustes c. coccothraustes] building three nests in a season. *British Birds* 24(4): 103. 1930.

8974. COLTHRUP, C. W. Westward migration of swallows and martins in north Kent in autumn. *British Birds* 24(1): 28-29. 1930.—*Hirundo r. rustica* and *delichon u. urbica*.

8975. COMTE, A. Les ébauches de nids d'oiseaux. *Bull. Soc. Zool. Genève* 4(2): 152-154. 1930.—Many Swiss birds begin nests without finishing them, because they find the site unsuitable or for other reasons.

8976. DIETRICH, ERICH. Ueber die Begattung bei der Amsel, Turdus m. merula L. *Mitteil. Ver. Sächs. Ornithologen* 2(5): 232. 1929.—An account of the mating of this species, observed in Saxony.

8977. DOBBRICK, W. Fichtenkreuzschnabeldurchzug bei Oestl. Neufähr 1929. *Der Vogelzug* 1(2): 95-96. 1930.—The Crossbill migration near Danzig, 1929 from June to Nov., was chiefly toward the west.

8978. DROST, R. Schnepfenzug im Februar auf Helgoland. *Der Vogelzug* 1(2): 97-98. 1930.—Numbers of *Scolopax rusticola* appeared in early Feb., apparently driven by frost and snow from Scandinavia and Denmark.

8979. EDWARDS, V. C. WYNNE. Ecological studies of birds in Devon. *Bull. British Ornith. Club* 50(341): 65-67. 1930.—Summary.

8980. ELLIOTT, J. S. Cuckoo removing another cuckoo's egg from a nest and its sequel. *British Birds* 24(2): 53-54. 1930.—A *Cuculus canorus* while visiting a nest of *Motacilla alba yarrellii* to lay in it, evidently

devoured another cuckoo's egg already there. Later the second cuckoo's egg was destroyed, perhaps by the wagtail.

8981. **GARNETT, R. M.** Little gull feeding on earthworms. *British Birds* 23(10): 278-279. 1930.—*Larus minutus*, in a field being ploughed in England.

8982. **GREENAWAY, WM. HARRY.** Blackbird nesting on ground in Foula. *Scottish Nat.* 1930(184): 110. 1930.

8983. **HALDY, B.** Vogelbeobachtungen am Futterplatz. *Aus der Heimat* 43(1): 13-17. 1 fig. 1930.—Experiences in the winter-feeding of various birds in Germany.

8984. **HAMILTON, DAVID.** Linnets nesting among grass. *Scottish Nat.* 1930(184): 116. 1930.—In Haddingtonshire.

8985. **HOLLOM, P. A. D.** Number of young in nests of swallow and martin in Somerset. *British Birds* 23(9): 248-249. 1930.—In 38 nests of *Hirundo r. rustica* and 27 nests of *Delichon u. urbica* the average number of nestlings was, respectively, 4.48 and 3.1.

8986. **KUMMERLÖWE, H.** Schlafgemeinschaften von Schwalben. *Mitteil. Ver. Sächs. Ornithologen* 2(6): 288-289. 1929.—Thousands of swallows and sand martins roosting together in reed beds at Sempach, Switzerland, in Aug.

8987. **LACK, DAVID L.** Double-brooding of the Nightjar. *British Birds* 23(9): 242-244. 1930.—The author's observations in Norfolk indicate that *Caprimulgus e. europaeus* normally rears 2 broods during the summer. The ♂ begins brooding the chicks when they are 10-14 days old, at which time the ♀ has evidently begun to incubate a 2nd set of eggs.

8988. **MEIKLEJOHN, A. H.** Extraordinary display by a pair of hedge-sparrows. *British Birds* 23(9): 255. 1930.—Mating behavior.

8989. **PETTINGILL, OLIN S. Jr.** Observations on the nesting activities of the hermit thrush. *Bird-Banding* 1(2): 72-77. 3 fig. 1930.—In Michigan.

8990. **PITMAN, C. R. S.** Some notes on the breeding of the dwarf goose Nettopus auritus (Bodd.) in Uganda. *Oologists' Rec.* 10(2): 26-27. 1 fig. 1930.

8991. **PITMAN, C. R. S.** The eggs of the standard-wing Nightjar, Macrodipteryx longipennis (Shaw). *Oologists' Rec.* 10(2): 27-28. 1930.—Measurements and description of eggs are given.

8992. **PITMAN, C. R. S.** Additional notes on the breeding of the long-tailed Nightjar, Scotornis climacurus (Vieill.). *Oologists' Rec.* 10(2): 29-32. 1930.

8993. **POWELL, T. G.** Ringed plover's double brood. *British Birds* 24(4): 109. 1930.—*Charadrius h. hiaticula*, in Suffolk.

8994. **PREBLE, EDWARD A.** Our owls in fable and fact. *Nature Magazine* 15(3): 143-148. 1 pl. 11 fig.; 188-189. 1930.—Notes on the habits of 16 American spp.

8995. **QUANTZ, B.** Weiteres zur Gestalt des Flugloches der Schwarzspecht-Nisthöhle. *Ornithol. Monatsschr.* 55(6): 94-95. 1930.—The orifices of the black woodpecker's nest-hole tend to be circular in western Europe, more oblong in more eastern localities.

8996. **ROBIEN, PAUL.** Opfer des Vogelzuges an der Küste. [Casualties of bird migration on the coast.] *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung* 1(1): 47. 1930.—A list of many birds, apparently victims of cold or stormy weather, which were found on the coast of Pomerania.

8997. **ROBINSON, H. W.** Starlings nesting in fork of tree. *British Birds* 23(9): 253. 1930.—In England.

8998. **ROTHSCHILD.** [Breeding of Grus antigone.] *Bull. British Ornith. Club* 50(341): 67-68. 1930.—In captivity.

8999. **RÜPPELL, WERNER.** Vom Frühjahrszug des Weissen Storches 1930. *Ornithol. Monatsschr.* 55(8): 116-118. 1930.—In this year the white stork, *Ciconia ciconia*, migrated in unusual numbers in west-east direction along the Kurische Hoff, East Prussia.

9000. **RUSSELL, G. R.** Flocks of cuckoos on migration. *Scottish Naturalist* 1930(183): 94. 1930.—In Scotland, April 27.

9001. **RYVES, B. H.** Late breeding of magpies. *British Birds* 23(9): 248. 1930.—On a Cornwall farm, where magpie nests are regularly destroyed, a brood did not leave the nest till about Nov. 10. This indicates the tenacity of the species in reproduction.

9002. **SERLE, WILLIAM.** Fly-catching action of skylark. *British Birds* 24(4): 105. 1930.—*Alauda a. arvensis* in Holland.

9003. **STADLER, HANS.** Die Stimme des Habichtskauzes (Syrnium uralense Pallas). *Ornithol. Monatsschr.* 55(8): 113-116. 5 fig. 1930.—A detailed study of the notes of the Ural owl in East Prussia, especially in comparison with those of the tawny owl.

9004. **STANBERY, C. B.** A strange nest. *Bird-Lore* 32(3): 202. 1930.—Bronzed Grackle nesting in a box, in Tennessee.

9005. **STEVENS, O. A.** "The white-throated sparrow." *North & South Dakota Hortic.* 2(9): 13-15. 1930.—Note on migration.

9006. **TALLIS, T. R.** Young kestrels killing smallest of brood. *British Birds* 24(4): 107. 1930.—*Falco t. tinnunculus*, in Breconshire.

9007. **THOMAS, EDUARD.** Fangballspiel einer Saatkrähe. *Aus der Heimat* 43(1): 29. 1930.—A rook in flight repeatedly tossed a small object from its bill and caught it again in the air.

9008. **WHARTON, WILLIAM P.** A white-throated sparrow return-4 W. *Bird-Banding* 1(2): 84. 1930.—A banded bird recorded for 5 successive winters at Summerville, S. Carolina.

9009. **W[HITTLE], C. L.** An old white-breasted nuthatch. *Bird-Banding* 1(2): 83. 1930.—A banded bird in New Hampshire at least 7½ yrs. old.

9010. **W[HITTLE], C. L.** A wood thrush return-1 S. *Bird-Banding* 1(2): 83. 1930.—A banded *Hylocichla mustelina* recorded in 2 different summers at New Haven, Connecticut.

9011. **WHITTLE, C. L.** A song sparrow return and recovery. *Bird-Banding* 1(2): 83-84. 1930.—A banded bird recorded in Massachusetts in late summer, 1925 and 1926, and in western New York in Sept., 1929.

LOCAL AND FAUNISTIC

9012. **CLELAND, J. B., et al.** [Notes on birds.] *S. Austral. Ornithol.* 10(4): 124-143. 1929.—Articles dealing with records of and notes on the birds of various localities in S. Australia and the Western District of Victoria, and on additions to the collection of the S. Australia Mus. A description is given of the flesh of the Yellow-nosed Albatross (*Diomedea chlororhyncha*) and measurements of Giant Petrels (*Macronectes giganteus*).—*J. B. Cleland.*

9013. **KÖHLER, RICH., und RUD. ZIMMERMANN.** Eine noch unbekannte Siedlung der Saatkrähe, Corvus fr. frugilegus L., in Sachsen. *Mitteil. Ver. Sächs. Ornithologen* 2(6): 283-284. 1929.—A recently discovered rookery, containing about 200-250 pairs, is the second one known at present in the lowland of northern Saxony.

9014. **KUBLI, HANS.** Zwei seltene Brutvögel im st. gallischen Rheintal. *Jahrb. St. Gallischen Naturwiss. Ges.* 64: 74-81. 1 pl. 1928(1929).—In recent years the author has found in the Rhine Valley in St. Gallen, Switzerland, several colonies of *Turdus pilaris**, which is extending its breeding range southward. Details of the nesting are given. *Sterna hirundo** has become quite rare, owing to the scarcity of nesting sites and frequent destruction of nests by floods.

9015. **[LORETS, V. F.]** ЛОРЕЦ, В. Ф. Список птиц окрестностей Сарепты. [An annotated list of the birds in the vicinity of Sarepta, southeastern European Russia.] Известия Саратовского Общества Естествоиспытателей. (*Ber. Saratower Naturforscherges.* [*Saratow*]) 3(1): 73-95. 1929.—Two hundred and seventy spp. are listed, common names in Russian, German, and Latin being given.

9016. **PETIT, L.** Observations ornithologiques faites

au cours de l'hiver 1929. *Bull. Soc. Zool. France* 54: 270. 1929.—The unusually cold winter of 1929 caused the death of thousands of small birds and drove various northern water birds into the interior of France.

9017. **PRINZ, H. Das Vorkommen der Wasseramsel, Cinclus c. aquaticus (Bechst.), als Brutvogel an der Roten und Wilden Weisseritz.** *Mitteil. Ver. Sächs. Ornithologen* 2(5): 194-201. Map. 1929.—A record of nesting dippers on these 2 streams in the years 1924-28.

9018. **SCHAUB, S. Über einen neuen Riesenvogel aus den Teredinasanden von Monthelon bei Epernay. [A new gigantic bird from the Teredina sands of Monthelon near Epernay.]** *Verhandl. Schweizer. Naturforsch. Ges.* 110: 195. 1929.—Descriptions of tarsal and toe elements, provisionally referred to *Diatryma*, Ypresian (Lr. Eocene).

9019. **SCHORGER, A. W. The birds of Dane County, Wisconsin.** [To be concluded.] *Trans. Wisconsin Acad. Sci. Arts & Lett.* 24: 457-499. 2 pl. 1929.—Introductory remarks on physiography, principal trees, life zones, and seasonal distribution are followed by a systematic list of spp., including notes on status, habits, food, voice, breeding, etc. The present instalment covers the families from Gaviidae to Picidae.

9020. **SCHOUTEDEN, H. Un genre de Ploceides nouveau pour la faune congolaise.** *Rev. Zool. Bot. Africaines* 17(3): 379-380. 1929.—*Ploceipasser superciliosus brunnescens* Grote was taken at Mahagi, on Lake Albert, and *P. rufoscapulatus* at Elizabethville, Katanga.

9021. **SCHÜZ, E. Vom Frühjahrs-Durchzug des Polar-Seetauchers, Colymbus arcticus L., auf der Kurischen Nehrung.** *Mitteil. Ver. Sächs. Ornithologen* 2(6): 289-294. 1 pl., 1 fig. 1929.—From May 19 to 25 migrating flocks of the black-throated diver passed over in late afternoon, chiefly in a northwesterly direction.

9022. **SEEMAN, ERNEST. A catalogue of the birds of Durham County, North Carolina.** *Jour. Elisha Mitchell Sci. Soc.* 45(1): 150-163. 1929.—The report is based upon observations made during a period of 31 years; 143 spp. and varieties are listed.—*R. E. Coker.*

9023. **SPENSE, REGINALD, S. H. PRATER, and SALIM A. ALI, editors. Migration of wildfowl.** *Jour. Bombay Nat. Hist. Soc.* 33(3): 719-720. 1929.—A note.

9024. **[VELIKOKHAT'KO, F.]** ВЕЛИКОХАТЬКО, Ф. Про деяких рідких птахів Білоцерківщини. **[Some rare birds of Bila Zerkva, Ukraine.]** [German summary.] Всеукраїнська Академія Наук, Труды Фізично-Математичного Відділу (Збірник Праць Зоологічного Музею ч. 7) (*Acad. Sci. Ukraine, Mém. Cl. Sci. Phys. et Math.*) (*Trav. Mus. Zool. No. 7*) 13(1): 195-202. 1929.—Notes on 20 spp.

9025. **VIETINGHOFF-RIESCH, A. Materialien zur Ornis der sächsischen und preussischen Lausitz.** *Mitteil. Ver. Sächs. Ornithologen* 2(6): 256-283. 1929.—Notes on the distribution and habits of numerous spp.

GERRIT S. MILLER, *Editor*

REMINGTON KELLOGG, *Associate Editor*

(See also in this issue Entries 6101, 6401, 7558, 7564, 7677, 8181, 8212, 8213, 8231, 8232, 8235, 8266, 8330, 8337, 8859, 9051, 9056)

9026. **CABRERA, ÁNGEL. Sobre el supuesto antropóideo de Venezuela. [The supposed anthropoid from Venezuela.]** *Physis* [*Buenos Aires*] 10(35): 204-209. 1930.—*Ameranthropoides loysi*, recently described by Montandon as a representative of a new family, is in reality a member of the Cebidae (subfamily Atelinae). It represents a new sp., and possibly a new genus, but contributes nothing new to the question of the phylogeny of the Primates, as supposed by Montandon.

9027. **CASTELLANOS, ALFREDO. Nuevos restos del hombre fósil. (Nota informativa.) [New remains of fossil man.]** *Physis* [*Buenos Aires*] 10(35): 175-181. 3 fig. 1930.—A mandible*, from the Middle Pleistocene(?) and presumably from the Province of Buenos Aires, is described. It provides further evidence of the existence of *Homo sapiens* in South America much earlier than in Europe.

9028. **DAL PIAZ, GIAMBATTISTA. Nuovo genere e nuove specie di Artiodattili dell'oligocene veneto. [New genus and new species of Artiodactyla from the Venetian Oligocene.]** *Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. e Nat.* 12(1/2): 61-64. 1930.—**ANTHRACOCHOERUS** (p. 62), *A.* **stehlini** (type) (p. 63), and *A.* **fabianii** (p. 63), both from Lower Oligocene (Sannoisian), types in Mus. Geol. Padova. These forms show some resemblance to the Anthracotheridae and the Suidae, but apparently belong to some group distinct from either family.

9029. **EHRENBERG, K. Zur Frage der systematischen und phylogenetischen Stellung der Bärenreste von Hundsheim und Deutsch-Altenburg in Niederösterreich.** *Palaeobiologica* [*Wien*] 2(4/5): 213-221. 2 pl. 1929.—Investigation of the material in the Museum of Natural Sciences in Vienna, carried on with especial view to an analysis of dental components, led to the conclusion that the bear from Hundsheim, previously studied by Freudenberg, manifested individual spelaeoid features common to arctoid habits, whereas the bear from Deutsch-Altenburg should be classed as a typical *Ursus spelaeus* with distinct arctoid characteristics. In conclusion the work points to the concurrence of this fact with the opinion expressed elsewhere by the author on the phylogenesis of brown bears.—*K. Ehrenberg* (*transl.*).

9030. **GILLESPIE, ALEX. S. Some observations of the chamois. Rupicapra rupicapra Linn. (R. tragus Gray).** *No. Western Nat.* [*Scotland*] 5(3): 148-150. 1930.—Field note.

9031. **HATT, ROBERT T. The biology of the voles of New York.** *Roosevelt Wild Life Bull.* 5(4): 513-623. 17 pl. (1 col.) 1930.—An extensive review is given of the life histories of *Microtus pennsylvanicus, Clethrionomys gapperi, Pitymys pinetorum scalopsoides,* and *Synaptomys cooperi.* It is concluded that the voles are highly beneficial except where locally over-abundant. Adequate protection from the voles may be afforded by elimination of their habitats and encouragement of their enemies. Extensive bibliography.—*R. T. Hatt.*

9032. **HATT, ROBERT T. The relation of mammals to the Harvard Forest.** *Roosevelt Wild Life Bull.* 5(4): 625-671. 11 pl. 1930.—The Harvard Forest at Petersham, Mass., consists of various natural forest types and plantations which are chiefly pure stands. Red squirrels damage plantations of European larch, Scotch pine, Norway spruce. Porcupines injure larch, Scotch pine and hemlock. Microtines girdle Scotch pine in plantations. Deer feed on ash growing in natural stands. Injury has resulted chiefly from putting small plantations of tree species subject to mammal damage adjacent to natural forests in which the winter food supply is inadequate. The planting of pure stands has proved inadvisable as such stands have a high amount of mammal and insect damage and where there is extensive destruction of the trees the plantation becomes a total loss. Notes on other mammals of the Forest are recorded.—*R. T. Hatt.*

9033. **HUGUES, ALBERT. [Two local mammals.]** *Bull. Soc. d'Étude Sci. Nat., Nimes* 44: 155. 1926.—*Myotis nattereri,* new to Gard; beaver spreading up the Gardon River.

9034. **KELLOGG, REMINGTON. A new fossil toothed whale from Florida.** *Amer. Mus. Novitates* 389. 10p.

3 fig. 1929.—**KOGIOPSIS** with *K.* **floridana*** (p. 2), is based on the symphysial portion of the lower jaws, from land pebble phosphate deposits (Upper Miocene or Lower Pliocene) of Polk Co., Florida. This genus resembles *Kogia* in the implantation of the teeth, but differs in being of larger size, and in having a broader mandibular symphysis, which bears 6 instead of 8 teeth. *Kogiopsis* is referred tentatively to the Kogiidae.—*L. S. Russell.*

9035. MAXSON, JOHN H. A Tertiary mammalian fauna from the Mint Canyon formation of southern California. *Carnegie Inst. Washington Publ.* 404. 77-112. Map. 17 fig. 1930.—The fauna is probably near the Middle of the upper Miocene. It includes 2 Testudinata; a fragment of a bird; *Aelurodon* sp.* [Carnivora]; *Hypolagus* ? cf. *apachensis** [Lagomorpha]; *Trilophodon* sp.* [Proboscidea]; *Parahippus* ? aff. *mourningi**, *Merychippus sumani**, *M.* sp., *M. intermontanus**, *Protohippus* sp.*, *Hipparion* ? sp. *A**, *H.* ? sp. *B**, and *H.* ? aff. *mohavense** [Equidae]; fragment of a rhinocerotid; *Prosthennops* ? sp.* [Dicotylidae]; *Miolabis* **californicus*** (p. 106), type in Univ. of California, and *Alticamelus* ? sp.* [Camelidae]; *Merycodus* aff. *necatus** and antilocaprid indet. [Antilocapridae]; oreodont cf. *Merychyus** [Oreodontidae].

9036. MILLER, GERRIT S. Jr. A note on the skeletons of two Alaskan porpoises. *Smithsonian Misc. Coll.* 82(13) : 1-2. 1 pl. 1930.—The peculiarities in the skeleton of *Phocoenoides dalli** are pointed out, comparison being made with *Phocaena phocoena**.

9037. MILLER, GERRIT S. Jr. The supposed occurrence of an Asiatic goat-antelope in the Pleistocene of Colorado. *Smithsonian Misc. Coll.* 82(14) : 1-2. 2 pl. 1930.—The leg bones upon which *Nemorhoedus palmeri** Cragin was based prove to be those of *Ovis canadensis** Shaw.

9038. MILLER, GERRIT S. Jr. Three small collections of mammals from Hispaniola. *Smithsonian Misc. Coll.* 82(15) : 1-10. 2 pl. 1930.—Remains of 8 mammals were obtained in a crevice in Haiti, probably once the nesting place of the giant Haitian barn owl. *Rattus rattus* is the only introduced European rodent represented. Canines of *Nesophontes* exhibit sexual dimorphism, a condition perhaps unique among insectivores. Comparison of the skull of *Brotomys* with that of the mainland *Proechimys* shows that they are no more than generically distinct. A collection of 6 forms from caves on Gonave Is. includes most of the genera of extinct mammals found in caves of the Haitian mainland. The author also reports on 7 forms derived from owl pellets (probably of the small living barn owl) and on 6 forms (besides remains of 3 European mammals) from an Indian deposit in the Dominican Republic. The presence of remains of *Nesophontes*, *Brotomys*, and *Isolobodon* in fairly fresh owl pellets indicates that members of these supposedly extinct genera may be still alive. The presence of remains of *Cavia porcellus* in the Indian deposit raises the question whether this South American animal was introduced by early native trade or by the Spaniards.

9039. OGNEV, S. J. Übersicht der in der russischen Fauna einheimischen Springmäuse der Gattung Dipodipus. *Zool. Anz.* 91(5/8) : 207-216. 2 fig. 1930.—The author treats 4 subspp. of *Dipodipus sagitta*, giving synonymy, type locality, description, and geographic distribution of each. The sp. ranges from southern Russia to Turkestan and Siberia. *D. s.* **innae** (p. 207), southern Russia, type in author's coll.

9040. PARODI, RODOLFO. Contribución a la osteología de los grandes felinos vivientes de la Argentina. [Osteology of the large living cats of Argentina.] *Physis [Buenos Aires]* 10(35) : 74-84. 2 pl., 2 fig. 1930.—The author proposes to unite *Felis onca, F. leo,* and *F. tigris* in the subg. *Panthera*, but disagrees with Pocock's conception of the genus *Panthera* and subfamily Pantherinae. He gives a detailed description and comparison of the skulls of *F. onca** and *F. puma**, with a few notes on other skeletal parts. There are also brief remarks on the skulls of *F. concolor* and *F. pardalis.*

9041. REGAN, C. TATE. The evolution of the Primates. *Ann. and Mag. Nat. Hist.* 10th Ser. 6(34) : 383-392. 1930.—Five sub-orders are recognized: (1) Lemuroidea (Lemuriformes auct.); (2) Lorisoidea (Lorisiformes auct.+Omomyidae); (3) Tarsioidea; (4) Platyrrhina; (5) Catarrhina. The Lemuroidea include the Madagascar lemurs, and the Eocene Adapidae, which are the most generalized Primates known. The Catarrhina originated in Africa direct from Lemuroidea, which group also gave rise to the Lorisoidea, and these in turn to the Tarsioidea in Europe and to the Platyrrhina in South America. The structure and distribution of recent and extinct Primates is discussed.—*C. T. Regan.*

9042. ROMER, ALFRED S. A fresh skull of an extinct American camel. *Jour. Geol.* 37(3) : 261-267. 5 fig. 1929.—The author describes a skull of the camel, *Camelops hesternus**, found in a cave at Fillmore, Utah. No replacement of the bone has taken place; the ventral surface still retains traces of the rectus capitis muscles; the mastoid and paroccipital are seen to be closely united for much of their length, the glenoid is situated well up the side of the brain case, there are large post-temporal openings, and the specimen well illustrates the characteristic difference in position of the orbits in the extinct and the living genera. The author concludes from this evidence that a native American camel, supposedly extinct since the early Pleistocene, existed until recently in the Great Basin region.—*D. J. MacNeil.*

9043. RUSCONI, CARLOS. Sobre anomalías dentarias numéricas en algunos guanacos vivientes (Lama guanicoe Müller). [Supernumerary teeth in some living guanacos.] *Physis [Buenos Aires]* 10(35) : 199-203. 3 fig. 1930.—Two cases of supernumerary premolars* in *L. guanicoe* are described. This anomaly is interpreted as numerical rather than atavistic and reversional.

9044. ST. LEGER, J. A short description of two new species of Dendromus from S. W. Africa. *Ann. and Mag. Nat. Hist.* Ser. 10 6(35) : 622. 1930.—*D. mesomelas* **major** and *D. nigrifrons* **shortridgei** (p. 622), Ssanukanu Village, Grootfontein District. Types in Brit. Mus.

9045. SCHWARZ, ERNST. Die Wildkatze der Balearen. *Zool. Anz.* 91(5/8) : 223-224. 1930.—*Felis catus* **jordansi** (p. 223), type in Mus. König, Bonn.

9046. SODY, H. J. V. On some new or insufficiently known mammals from Java, Borneo and Celebes. *Natuurkundig Tijdschr. Nederlandsch-Indië* 90(2) : 258-273. 1 pl. 1930.—An annotated list containing notes and descriptions, as follows: *Pithecus aygula fredericae**, *Callosciurus nigrovittatus madsoedi, Crocidura minuta, Cynopterus brachyotis angulatus, Hipposideros galerita galerita,* new to Celebes, *H. a longicauda. Miniopterus* **ravus** ♀ (p. 271), Java, *M.* **witkampi** ♂ (p. 272), Borneo, and *M. medius.*

9047. TRATMAN, E. K. Report on excavations in Ireland in 1928. *Univ. Bristol. Proc. Spelaeolog. Soc.* 3(3) : 109-125. 3 pl., 4 fig. 1928(1929).—A cave at Kilgreany was occupied by man in the Neolithic period and in the bronze and iron ages. Remains of a late Pleistocene fauna, including a field vole new to Ireland, were found.

9048. [VINOGRADOV, B. S., and S. I. OBOLENSKII.] ВИНОГРАДОВ, Б. С. и С. И. ОБОЛЕНСКИЙ. Вредные насекомые и другие животные в СССР. I. Вредные грызуны. Данные по биологии и систематике. II. Борьба с грызунами в СССР. в 1925-1928 гг. **[Injurious insects and other animals in USSR. I. Habits and classification; II. Rodent control in USSR. in 1925-1928.]** [English summary.] Всесоюзная Академия С. Х. Наук им. Ленина. Труды по Прикладной Энтомологии (*Lenin Acad. Agric. Sci. Works of Appl. Ent. Leningrad*) 13(5) : 257-324. 1930—Paper 1 contains abstracts of various papers published during 1925-1928. Paper 2 is based on reports of Plant Protection Stations and Depts. of Agric. Among the rodent pests the following are mentioned: in the north, rats and mice in stores, water-rats, and rabbits in gardens; spermophiles and

field mice are common pests in the central region; spermophiles, mice, water-rats, rabbits and others are the best known pests in the Volga region, Ukraine and North Caucasus; spermophiles are absent in Transcaucasia, but mice are very noxious; in central Asia the *Nesokia, Hystrix, Spermophilopsis, Citellus,* and many spp. of mice and rats are common; in Siberia squirrels, water-rats, mice, *Myospalax,* hamster (*Cricetus cricetus*), and chipmunk are of economic importance; and in the Far East, the caraco-rat (*Rattus norvegicus caraco*) is very injurious to rice.

9049. WALLIS, C. W. K. Notes on British bats—with special reference to those of the Midland Plateau. *Proc. Birmingham Nat. Hist. and Philos. Soc.* 16(1): 1-12. 1930.—Eight spp. are recorded from the Midland Plateau, and 4 others are recognized on the British list. The author gives a brief description of each and detailed notes on flight, feeding, roosting, and other habits.

9050. YOUNG, C. C. On the mammalian remains from Chi Ku Shan near Chou Kou Tien. [Chinese summary.] *Geol. Surv. China. Palaeontol. Sinica* C 7(1): 5-19. 2 pl., 1 fig. 1930.—The following are described: *Canis** sp. and *Vulpes* **chikushanensis*** (p. 7) [Canidae]; *Meles* cf. *leucurus** [Mustelidae]; Muridae indet.; *Hystrix* sp. [Hystricidae]; *Lepus* cf. *oiostolus** [Leporidae]; *Cervus* sp. [Cervidae]. The Chi ku Shan deposits apparently correspond to the near-by *Sinanthropus* deposits. The location was probably a fissure, where rodents were brought in by carnivores. There is a bibliography of 12 titles.

SYSTEMATIC ZOOLOGY

(GENERAL)

9051. BANZHAF, WALTER. Zur Fauna der Greifswalder Oie. *Dohrniana* [*Stettin*] 11: 190-236. 11 fig. 1931.—A description of this small island off the coast of Pomerania is followed by annotated lists of insects, mollusks, amphibians, reptiles, birds, and mammals found during a visit in July.

9052. GRAHAM, DAVID. A collecting trip to Washan and Mount Omei. *Jour. West China Border Res. Soc.* 3: 30-33. 1926/29[1930].—Narrative of a zoological expedition to mountains of Szechwan in 1925.

9053. JOANNIS, J. de. Les règles internationales de nomenclature zoologique. *Amateur de Papillons* 5(13): 193-201; 5(14): 209-217; 5(16): 245-252. 1931.

9054. MacGINITIE, G. E. Notice of extension of range and of new species of various invertebrates. *Ann. & Mag. Nat. Hist.* 6(31): 68. 1930.—Of 14 spp. mentioned as occurring at Monterey Bay, 8 were known from other parts of California, one, *Phyllaplysia taylori,* had been known only from Brit. Columbia, and 5 have been recently described as new.

9055. MARR, J. E. Fossil vertebrates. *Nat. Hist. Wicken Fen* Pt. 4. 298-299. 1928.—In the fens of Cambridgeshire have been found skeletons of 12 birds, 7 ungulates, 2 rodents, 6 carnivores, and of man.

9056. MEER MOHR, J. C. van der. Notes on the fauna of Pulau Berhala. *Treubia* 12(3/4): 277-298. Map. 3 fig. 1930.—The topography and vegetation of this group of 2 small islands off the E. coast of Sumatra are briefly described. The various faunal elements are discussed, and lists are given of 4 mammals, 24 birds, 16 reptiles, 1 amphibian, 20 ants, 8 Hemiptera, 20 Orthoptera, 27 spiders, 4 Acari, 10 mollusks, and 5 Oligochaeta.

9057. MÜLLER, ARNOLD. Contribuţiuni la cunoaşterea faunei Insulei Şerpilor. [The fauna of Serpent Island (Black Sea).] *Intâiul Congr. Nat. Naturalişt. România* 1: 337-344. 1928(1930).—Two birds, 1 reptile, and 35 arthropods are listed.

9058. SCHULZE, F. E., W. KÜKENTHAL, K. HEIDER, fortgesetzt von R. HESSE, Schriftleiter: TH. KUHLGATZ. Nomenclator animalium generum et subgenerum. Band 3. 1939-2098. Preussischen Akademie Wissenschaften: Berlin, 1931.—Includes letters Macroglossap.—Microto.

9059. TOLMER, L. Notes sur la faune marine de la région de Luc-sur-Mer. Juillet-Septembre 1928. *Bull. Soc. Linn. Normandie* 1: 77-80. 1928(1929).—Records of collecting certain Coelenterata, Echinodermata, Vermes, Nemertea, Crustacea, and Mollusca.

9060. WOLFF, MAX, und ANTON KRAUSSE. Die wirbellosen Tiere. Eine systematische Uebersicht. [Invertebrate animals. A systematic review.] 350p. 337 fig. Gustav Fischer: Jena, 1930. Pr. 20 M.

9061. ANONYMOUS. Plymouth marine fauna. 2nd ed. Compiled from the records of the Laboratory of the Marine Biological Association. 371p. Marine Biological Assoc. of the United Kingdom: Plymouth, England, 1931. Pr. 2s. 6d.—The first section of this volume consists of a description of the grounds and of the physical conditions that obtain in certain typical areas of the Plymouth district, together with a brief characterization of the fauna of these particular areas. The second section contains a detailed list of the various species of animals (Protozoa, Porifera, Coelenterata, Ctenophora, Platyhelminthes, Nemathelminthes, Nemertea, Annelida, Rotatoria, Sipunculoidea, Gephyrea, Phoronidea, Crustacea, Pycnogonida, Insecta, Mollusca, Echinodermata, Bryozoa, Prochordata and Pisces) that have been recorded from the entire district. The information thus supplied in the 2 sections, when combined, furnishes for each species a general idea of the conditions under which it lives.—*C. Juday.*

9062. ANONYMOUS. Regole per la nomenclatura zoologica italiana. [Rules for Italian zoological nomenclature.] *Boll. Zool. Unione Zool. Italiana* 1(2): 83-88. 1930.

HISTORY AND BIBLIOGRAPHY

9063. **ADAMS, J. A bibliography of Canadian plant geography to the end of the year 1920; 1921-1925.** *Trans. Roy. Canadian Inst.* 17(2): 227-265, 267-295. 1930.—The present installments contain citations 1755-2765, arranged alphabetically, comprising the literature of 1911-1925. Citations on fungi, plant diseases, algae, and bryophytes are included.

9064. **BOTHA, C. GRAHAM. An 18th century ms. on agricultural improvement at the Cape.** *S. African Jour. Sci.* 27: 573-575. 1930.

9065. **BRAUER, LUDOLPH, ALBRECHT MENDELSSOHN-BARTHOLDY, et al. Forschungsinstitute, ihre Geschichte, Organisation und Ziele. [Research institutes—their history, organization, and aims.] Band 1 und 2. 470p. Paul Hartung: Hamburg, 1930. Pr. 80 M.**

9066. **CORNING, HOWARD (editor). (Foreword by RUTHVEN DEANE.) Journal of John James Audubon, made during his trip to New Orleans in 1820-1821. 234p.** The Business Histor. Soc.: Cambridge, 1929.—This journal covers the period from Oct. 12, 1820, to Dec. 31, 1821. On the former date Audubon embarked at Cincinnati on a flat boat bound for New Orleans, which was reached on January 7. As he himself states his situation: "Without any money My Talents are to be My Support and My enthusiasm my Guide in My Difficulties, the whole of which I am ready to exert to [meet] keep, and to surmount." The journal, which is published exactly as written, is not a continuous narrative but a series of jottings strung together practically without punctuation. The spelling is sometimes curious and by no means consistent. Notes of events and records and descriptions of birds are indiscriminately mingled, and the lack of punctuation often obscures the meaning. On the trip down the Mississippi frequent hunting excursions ashore were made, and there are many references to birds and animals seen. Many of the birds killed are carefully described and notes made of measurements, wt., food, and habits. There are many notes of birds now rare or extinct in that region; turkeys in abundance, ivory-billed woodpeckers common far north of their present range, and flocks of Carolina paroquets. In March, 1821, near New Orleans, he records the passage of millions of golden plover and the way they were being unmercifully hunted. After his arrival in New Orleans Audubon supported himself by giving drawing and music lessons. He complains frequently of being in low spirits, and also of the unappreciativeness of persons to whom he showed his drawings. As much time as possible was spent on his drawings, and the market was visited almost daily in search of birds. In June, 1821, he went to a plantation where he acted as drawing master to the family, remaining there or at similar places until Oct. After his return to New Orleans, the journal is principally a record of lessons given and anxiety for the arrival of his family; with references to money difficulties and birds obtained and drawn. Soon after the arrival of his wife and sons the journal ends. The whole gives a rather vivid picture of Audubon the man and of his work in preparing the "Birds of America."—*M. T. Cooke.*

9067. **CORNING, HOWARD (editor). (Foreword by FRANCIS H. HERRICK.) Journal of John James Audubon, made while obtaining subscriptions to his "Birds of America" 1840-1843. 173p.** The Business Histor. Soc.: Cambridge, 1929.—Audubon was at this time soliciting subscriptions for the octavo edition of the "Birds of America" and the "Quadrupeds," occasionally selling copies of the large work. For this purpose he undertook a series of journeys through New York, New England, Canada, and as far south as Richmond. Records of the books sold and money received are given as well as many interesting comments on persons visited, many of whose names are very familiar. While in Canada he was especially interested in obtaining specimens of animals new to him. The few comments on wild life deal mostly with mammals instead of with birds as heretofore, his interest being now centered on the preparation of the "Quadrupeds." The journal covers the period from Aug., 1840, when he was already in Boston, to Oct., 1842. In form it is quite different from the New Orleans journal, being a more connected record of events addressed to his family.—*M. T. Cooke.*

9068. **DUDYCHA, GEORGE J. Ideas of origin among the ancient Egyptians and Babylonians.** *Sci. Month.* 32(3): 263-269. 1931.—Although it is customary for writers who deal with the history of evolutionary thought to begin with the Greeks, there are the more ancient significant ideas of the Egyptians and Babylonians. Among the Egyptians Beb-er-tcher, the creator god, suggests "the boundless" of Anaximander; and Nu, the great watery abyss, in which all things are potential and to which all things return, suggests not only Anaximander but Augustine. They also emphasized the primacy of fire, the potentiality of all things in divine intelligence, and an epigenetic process through which souls pass on their way towards materiality. Among the Sumites and Semites water is considered the primal source of all things. The idea of conflict and subsequent triumph of the creator, which suggests Empedocles, was originated by the Semitic-Babylonians. Thus the Greeks were not the first to speculate about the origin of things.—*G. J. Dudycha.*

9069. **FULTON, JOHN F. A note on the origin of the term "physiology."** *Yale Jour. Biol. and Med.* 3(1): 59-62. 1930.—The word "physiologia" and its Greek original were used by classical writers as synonymous with "natural philosophy"—the study and description of all natural objects. The English derivative was used

in this sense down to the end of the 18th century. The first to employ the term "physiology," or its Latin original, in the more restricted sense, i.e., "the science of the normal functions and phenomena of living things," was apparently the French physician, Jean Fernel. In 1554 he published a volume entitled "Medicina" which, with a singularly modern air, was divided into 3 parts: "Physiologiae," "Pathologiae," and "Therapeutice." In the part devoted to physiology the structure and functions of the human body were set forth. Fernel's usage was taken up by other medical writers, and for a time the word was used to include the study of structure as well as function, and it was not until the beginning of the 19th century that "anatomy" and "physiology" were regularly used separately to designate different parts of a medical curriculum.

9070. **GUNDER, J. D. North American Institutions featuring Lepidoptera. XVII. Bishop Museum, Honolulu, T. H.** *Ent. News* 41(8): 249-252. 3 pl. 1930.

9071. **HÖFER. Der Einfluss von tierischen Erkrankungen auf Kriegsausgänge. Eine literarische Studie.** [Influence of animal diseases on the outcome of wars.] *Ergänzungsbände Zeitschr. Veterinärk.* Heft 2. 1-64. 1931.—A study from the Middle Ages to modern time, with bibliography.

9072. **[JULLY.] Communication sur les lettres adressées par Chapelier en mission à Madagascar au citoyen préfet de l'Ile de France (de Décembre 1803 à Mai 1805) extraites des archives de Port-Louis et annotées par M. Jully 1.** *Bull. Acad. Malgache* 4: 1-56. 1905/06(1928).—Several letters of Chapelier, who succeeded Michaux in natural history work in Madagascar, are printed. They include descriptions of new genera and sp. of plants, and notes on other branches of natural history. Apparently Chapelier made use of documents left by Michaux.

9073. **LABERNADIE, V. De l'ancienneté de la lèpre d'après les Védas.** *Bull. Soc. Path. Exotique* 24(3): 175-176. 1931.—Evidence is offered to show that (contrary to Jeanselme) leprosy is not mentioned in the most ancient of the Vedas, or before the Christian era.

9074. **LAMY, EDOUARD. Les conchyliologistes Bruguière et Hwass.** *Jour. Conchyliol.* 74(1): 42-59. 1930.—Biographic and historical notes are collated. The Hwass collection, which was utilized in preparation of the plates for the Encyclopédie Methodique, is now in the Geneva Museum.—*H. B. Baker.*

9075. **LEATHES, J. B. The Harveian oration on the birth of chemical biology.** *Brit. Med. Jour.* 2(3642): 671-676. 1930.—In the 17th century modern physiology was born with the work of Harvey and the work on respiration after Harvey's death by John Mayow [1643-1679], the all-but-forgotten author of "De respiratione." This tract corrected many of the current errors with regard to the physiology of respiration, defined a "something in the air" absolutely necessary for life which enters the blood in respiration (current theory taught that the air merely cooled the blood), and thereby anticipated Priestley and Lavoisier by more than a century in the recognition of the existence of O.

Virolleaud of the Phoenician cuneiform alphabet of Ras Shamra indicates that the symbols for the letters were roughly taken from representations of the position of the lips and tongue and confirms the writer's interpretation of the mouth symbolism in Sumerian cuneiform.

9084. **PAINTER, CHARLES F. The medical museum. Its rôle in the teaching of medical history.** *New England Jour. Med.* 204(20): 1047-1051. 1931.

9085. **PIRES de LIMA, J. A. Fora da aula.** [From the lecture halls.] 334p. Araújo & Sobrinho, Suc.: Porto, 1929.—This is a description of the progress of science in Portugal within the last 50 yrs., written in appraisal of the work done by a small group of men. The work of Portuguese scientists has been appreciated by France, So. America, Belgium, and has also found acknowledgement in the U. S. A. Good investigations have been made on tropical diseases, promoted more recently by contacts with scientists in African, French, and Portuguese colonies. At the close of the last century studies of anatomy, biology, histology, and surgery were in the foreground. As early as 1641 a surgeon worked at Porto, but political and economic difficulties stunted the growth of the sciences until within the last 30 yrs. The names luminescent among others are Ramón y Cajal; Ferreira da Silva; Carlos Ribeiro, and the geologist, Paulo Choffat.—*B. Bickel.*

9086. **POP, EMIL. Contributii la istoria botanicei Romanesti.** [History of Rumanian botany.] [With German summary.] *Bull. Grad. Bot. Muz. Bot. Univ. Cluj* 10(1/4): 185-196. 1930.—The first floristic researches in Wallachia begin with I. G. H. Kramer, who was a physician in Timişoara about 1720. He also described some plants collected during a journey through Oltenia. A later traveler, Abbate Domenico Sestini, described 30 plants from Wallachia and 46 collected while journeying through Siebenbürgen and the Banat. The first reliable floristic information we have from the Banat comes from Griselini in 1775-1776. He also describes drug and dye plants used by the natives. D. J. Leonhard (1786-1853), Professor in Sibiu (Hermannstadt), later preacher in Orăşti (Broos) gives, in his "Lehrbuch," an incomplete enumeration of the plants of Siebenbürgen, and also about 100 Rumanian plant names.—*Author's summary (transl. by B. S. Dodge).*

9087. **RAMSBOTTOM, JOHN. Aquatic fungi.** *Jour. Quekett Microscop. Club* 16(97): 151-166. 3 fig. 1931.—An address, dealing in a popular fashion with the early history of knowledge of aquatic fungi, particularly Saprolegniaceae, and with some facts regarding aquatic fungi, of interest chiefly to amateur microscopists.

9088. **SARTON, GEORGE. The history of science and the new humanism.** 178p. Henry Holt & Co.: New York, 1931. Pr. $2.00.—The common ground between humanism and science is the "new humanism" and its field of activity includes the history of science. This forms a natural bridge between the antagonistic literary and humanistic group which regards science as technique devoid of cultural values, and the scientific one which sees less value in the humanities, especially in the classics. Three chapters deal respectively with the history of science and the history of civilization, the East and the West, and the new humanism. In the 1st chapter the author notes the great significance of scientific discovery in diverting and moulding the course

of civilization. It has a permanence and continuity and therefore an aspect of progress not so clearly discernible in art, politics, or religion; but it also has an inseparable human quality which places it on a par with these other 3 aspects of human activity. It originates in curiosity and emerges in great scientific discoverers, whose ideas influence a multitude of others and thus permeate civilization. Opposition to a new idea is a measure of its destructive and constructive force and both useful and indispensable in its clarification and in giving it momentum. The 2nd chapter contrasts the contributions of the East and the West. "Ex oriente lux, ex occidente lex." From the point of view of experimental science in its present stage of development the opposition of the East and the West is extreme. However, historically the seed of science, including the experimental method and, in fact, the seed of all forms of science, came from the East. Greek science was sadly deficient in the experimental spirit, outside of medicine. Under the influence of Arabic alchemists and opticians and later of Christian mechanicians and physicists, it grew, though but slowly, until the 16th century. Four phases are distinguishable in the history of science: the empirical one of Egyptian and Mesopotamian knowledge; Greek rationalization; the period of mediaeval groping occupied by the pseudo-problems of the reconciliation of Greek philosophy with religious dogmas, during which science grew and then waned under Islamic influences; and the experimental period. Of these the 1st and much of the 3rd were oriental; the 2nd and 4th are western. The 3rd chapter is a defence of the cultural values of science as a factor in the new humanism. The intellectual conflict is not between romanticists and classicists, but between mystics and rationalists. Mysticism is sterile, but science not only conquers the material world, but reveals an immaterial one transcending that of poets and dreamers. Disinterestedness and humility characterize the scientific method. This method is of more importance than the discoveries made by it. The function of the history of science is to reveal the growth of this method. An outline of a proposed course in the history of science is given and its relations to a wider scheme for education incorporating the idea of the new humanism is discussed. The new humanism is thus a double Renaissance; a scientific one for men of letters, and a literary one for men of science.—*C. A. Kofoid.*

9089. SMOCK, J. C. The Greek element in English words. 2 parts: xiv+267p.; vi+356p. Macmillan: New York, 1931.—This book is a word register of above 130,000 English words derived (directly or indirectly) or coined (wholly or in part) from Greek. About 50,000 of these words are not accessible in general dictionaries and represent the newer terms in science. The 2 parts of the book are alphabetical lists: 1st, of the English words with their Greek originals beside them; 2nd, of these Greek words followed by columns of the English words formed from them. Thus under "genetic" are listed above 150 terms, chiefly from biology, chemistry, and medicine, and under the various forms of "gamos" about 300. Abbreviated labels designate the fields of thought in which the English scientific words are primarily current. Full entries of combining forms assist specialists seeking to coin new terminology and provide a clue to the meaning of future coinages. The meanings of the Greek words are supplied; or, when these meanings may be gathered from the English words, a Greek author's name is supplied to whose influence the use of the word is presumably due.—*E. F. B. Fries.*

9090. SWIFT, R. H. The sacred beetles of Egypt. *Bull. Southern California Acad. Sci.* 30(1): 1-14. 4 pl., 1 fig. 1931.—In Egypt, the habit of "keper," the beetle (*Ateuchus sacer*), of rolling the egg in dung until it becomes a great ball, later to incubate in the hot desert sun and bring forth young, led to "kheperā" meaning "he who turns" or "rolls," the personified symbol of the Sun. Since the dung ball became covered with clay, later to bring forth young, "kheperā" was the Creator, "he who creates all out of clay." The Sun's evident part in all growth soon elevated Kheperā to a primal part in the personification of life giving force. Emblems representing the scarab early came to be used as amulets and seals.

9092. THIENEMANN, AUGUST. Tjibodas, der javanische Berggarten. [Tjibodas, the Javanese alpine garden.] *Bericht Senckenbergisch. Naturforsch. Ges.* [*Natur u. Mus.*] 61(1): 40-48. 7 fig. 1931.—A sketch of the history, equipment, and surroundings of this institution.

9093. VERLAINE, L. L'âme des bêtes. Quelques pages d'histoire. 202p. Félix Alcan: Paris, 1931. Pr. 25 fr.—This is a summary of the development of the subject of animal behavior. The authors discussed, aside from those of the classical and mediaeval periods, are almost wholly restricted to the French or to those whose works have been translated into French. The work falls into 3 main subdivisions, treating respectively the classical, mediaeval, and modern periods. The classical period is dominated by the Aristotelean concept of the entelechy or soul with its vegetative, sensitive, and reasoning aspects. In the mediaeval period zoology was rehabilitated by Cantimpré, Beauvais, and Albert, the last named the teacher of Thomas Aquinas, to whose concept of the "estimative" is attributed the long prevalent idea of fixed and immutable instincts among the Neo-Thomistes. The modern period is regarded as beginning with Montaigne, Cardanus, and Bruno, and continued by Descartes and Malebranche. It was not until Leibnitz that there was a return to the ideas of Aristotle, but the influence of Thomas Aquinas continues through Reamur and Bonnet, down to Buffon. The precursors of transformism, Benoît de Maillet, Robinet, Bonnet, and especially La Mettrie, prepared the way for Condillac with his revolutionary ideas on the interrelations of habits and instincts, and the experimental method introduced by his pupil Leroy. Reactionary tendencies appear in the creationists represented by Virey, Fr. Cuvier, Flourens, Fée, and Fabre. Anthropomorphic interpretations are chargeable to Charles Darwin and his followers, Romanes and Espinas. A return to the fundamental ideas of Condillac involving the inheritance of habit is traced through Romanes, Edm. Perrier, and Espinas to Wallace, whose presentation meets the author's fullest approval. The modern experimental school; the theories of tropisms and trial and error; and Driesch's views are only briefly discussed.—*C. A. Kofoid.*

(See also in this issue Entries 9076, 9227, 9413, 9995, 10355, 10452, 10453, 10972, 11024, 11124, 11182, 11195, 11215, 11281, 11362, 11399)

GENERAL

9128. **BLAKESLEE, ALBERT F.** The genetic viewpoint. *Science* 73(1900): 571-577. 1931.—The establishing of fruitful viewpoints, not the amassing of facts, is the goal of advanced research. The genetic viewpoint is the most important biological contribution of the 19th and 20th centuries. Genetics would show the fallacy of the assumption that all men are equal, and emphasize the value of the exceptional individual in man as well as in economic plants and animals. It would help evaluate the relative influence of heredity and environment, direct attention to genetic causes of biological phenomena, and do away with many beliefs regarding inheritance of acquired characters. For biologists, it would teach the value of biological controls. A blending of viewpoints in cooperative investigations is suggested, and for the oncoming generation we can strive to strengthen genetic education.—*M. R. Salmon.*

9129. **MARCELLO, ALESSANDRO.** Il problema della eredità considerato dal punto di vista chimico-fisico. *Nuovo Giorn. Bot. Ital.* 37(2): 402-434. 1930.—Hereditary characters are dependent upon a necessary chemical condition, and heredity is the transmission of this condition of mobile equilibrium between reversible reactions, fluctuating and mutable under the action of modifying agents. It may be called chemical, or, more precisely, hereditary energy.—*From author's summary.*

PLANT

9130. **ANDERSSON-KOTTÖ, IRMA.** Variegation in three species of ferns. (Polystichum angulare, Lastraea atrata, Scolopendrium vulgare.) *Zeitschr. Indukt. Abstamm.- u. Vererb.* 56(2): 115-201. 2 pl., 5 fig. 1930.—Gametophytes of *P. angulare* var. *variegatum* are: green, pale non-viable, and two types of variegated, prothallia, one of which gives true-breeding green and variegated sporophytes behaving like parent. Phenotypical change from green to pale green coincides with a genotypical change. Breeding of the other 3 types has been observed. The mutated cell is oriented in regard to the actively growing point. The mutations are considered due to changes in the factor determining chlorophyll development, and this factor is assumed to exist in 7 states (C, c_1-c_6). Alteration in this gene is not quantitative and assumed to be periodic. *Lastraea atrata* shows variegation in sporophytes, but only dark gametophytes. The species is apogamous, both generations having the same number of chromosomes. *Scolopendrium vulgare* shows variegation in both generations. Dark gametophytes selfed or crossed give only green sporophytes which give dark gametophytes. Pale gametophytes selfed or crossed with any other pale or dark, give variegated sporophytes like parent sporophyte, and these again give dark and pale gametophytes. Reciprocal crosses are similar. Character of sporangium is not always determined by character of sporophytic tissue from which it arises. Each single sporangium gives but one kind of gametophyte. The mutation in sporophyte is reversible and probably does not occur later than the first archesporial cell.—*H. D. Hill.*

9131. **BRINK, R. A. A red-to-white mutation in maize. A probable somatic mutation of the gene for red pericarp in maize.** *Jour. Heredity* 20(7): 333-334. 1 fig. 1929.—An ear of maize with red pericarp and red cob, but showing a patch of white seeds and red cob, is described. The plant which produced the ear was a red-white heterozygote and was pollinated by white. In a progeny test the red seeds gave approximately equal numbers of reds and whites. Eleven seeds from the white patch gave all whites. The white area probably arose as a result of mutation in a vegetative cell of the gene for red pericarp.—*R. A. Brink.*

9132. **CHAUDHURI, H. Nutritive saltation in fungi.** *Jour. Indian Bot. Soc.* 10(2): 154. 1931.—Most saltations are nutritive phenomena due to cultivation on synthetic media, and can be made to revert to the original forms under proper conditions.—*W. Dudgeon.*

9133. **CLARK, CHARLES F. A Solanum hybrid resulting from a cross between Solanum fendleri and S. chacoense.** *Jour. Heredity* 20(8): 391-394. 1 fig. 1929.—A study was made of the F_1 generation. Dominance was clearly expressed in several of the characters which constitute the wide morphological differences between the parent species. These included habit of growth, color and pubescence of stems, pubescence of leaflets, shape of calyx and corolla lobes, color and shape of corollas, and size and taste of tubers. Hybrid vigor was very pronounced. A high degree of sterility was found in both ♂ and ♀ germ cells; which made an F_2 impossible.—*C. F. Clark.*

9134. **CONNORS, C. H. Further notes on peach breeding.** *Proc. Amer. Soc. Hort. Sci.* 25: 125-128. 1928.

9135. **DAVIES, P. A., and EDNA BENNETT. Abnormal branching in Ailanthus.** *Jour. Heredity* 20(7): 348-349. 1 fig. 1929.—In an abnormal branch from a normal tree, the branching is regular and from a flattened fan-shaped stem. The pith is continuous from stem to branch.—*L. M. Dickerson.*

9137. **HABER, E. S. Inbreeding the Table Queen (Des Moines) squash.** *Proc. Amer. Soc. Hort. Sci.* 25: 111-114. 1928.—It is possible to build up a pure line with fruits of uniform size, shape, and quality without diminishing their size. The next step is to secure uniformly high yielding strains. This will be comparatively easy since other desirable characteristics are already homozygous. Inbreeding may not necessarily decrease vigor and yielding capacity of the squash or pumpkin.—*Author's conclusions.*

9138. **HARLAN, HARRY V. The weedishness of wild oats.** *Jour. Heredity* 20(11): 515-518. 3 fig. 1929.—Observations on the extremely effective adaptability of wild oats.—*L. M. Dickerson.*

9139. **HARLAN, HARRY V., and MARY L. MARTINI. Earliness in F_1 barley hybrids.** *Jour. Heredity* 20(12): 557-560. 2 fig. 1929.—Earliness, measured by awn emergence, of 351 hybrids representing all but one of the possible combinations between 27 different parent strains was compared with the earliness of the parents. Wide variations were found, some being earlier and others later than the parental strains.—*L. M. Dickerson.*

9140. **HUBER, J. A. Vererbungsstudien an Gerstenkreuzungen. II. Zur Genetik der Gerstenähre.** *Zeitschr. Zücht. Reihe A, Pflanzenzücht.* 16(3): 394-464. 11 fig. 1931.—Multiple allelomorphs are assumed for row number where $Z'Z'$ represents *deficiens*, ZZ *distichum* and zz *polystichum*. Four gene pairs, secondary to the foregoing, are concerned with formation of side spikelets but the data do not permit definite statements as to segregation. In awning, 1 gene pair, *Ar-ar*, is concerned

either with presence of awns or with "caput" formation. Barbing of the awns is due to 2 gene pairs with a cumulative effect. A gene, *Gw*, is suggested for deciduousness of awn. Ear density is conditioned by a series of 4 gene pairs, 3 of which, L_{1-3}, result in a loose ear when in a dominant condition. A gene, *Zeoc*, is responsible for the "zeocritium" head appearance, while another gene *Q* acts contrary to the foregoing in thickening the head in the distal portion. Three genes were worked out for glume color, *M* for black, *O* for orange and *P* for purple, all of which are paired with lack of color. At least 2 genes bring about kernel color; *Sch* colors the seed coat black while *Al* (and perhaps another) colors the aleurone layer blue. A gene, *N*, determines tightness of hull, the naked condition being recessive. A gene was found determining hairiness of the basal bristle and adjacent parts. Two genes, *G* and *G'*, acting together determine the toothed condition of the nerves upon the dorsal portion of the outer glumes; the toothed condition is dominant. Data are presented to show the existing of 2 genes, *Macr* and *Plat*, working independently which influence the width and ruggedness of the inner glumes. The segregation of one cross indicated a single gene, *V*, for branching of the head of certain varieties. Besides the genes indicated, others are listed which have been worked out by others; a few, previously listed by others, are given new terminology, and a modification of their reaction is noted. Most of the genes for which data are given are unifactorial.—A system of gene groupings is attempted, following the earlier ideas of Kuckuck. Four of the 7 possible groups are as follows: I. (8 genes) *Ar*, awn inhibitor; *Q*, thick head form; *Z*, number of head rows; *W*, side-spikelet inhibitor; *G*, outer glume serrations; *V*, branched head axes; *Macr*, broadening of inner glumes; L_3, looseness of ears. II. (4 genes) *M*, black glume color; *Sch*, black pericarp; *Gr*, serration of awns; *A*, pubescence of basal bristles. III. (7 genes) *T*, formation of side spikelets; *S*, extension of pubescence of the outer glume; *Zeoc*, 3-angled ears; *C*, ear thickness; *N*, tightness of glume; *Plat*, intensity of glume broadening; *G*, awn length. IV. (2 genes) *K*, "caput" glumes; *Al*, blue aleuron. The 2 genes L_2 and L_3 were not located.—*L. R. Waldron.*

9141. JENKIN, T. J. Inheritance in Lolium perenne L. III. Base-colour factors C and R. *Jour. Genetics* 22(3): 389-394. 1930.—Confirmatory evidence is presented that complementary factors *C* and *R* are concerned with the production of red base color in *Lolium perenne*. In the absence of either of these no red base-color is developed. —*R. J. Garber.*

9142. JENKINS, MERLE T., and MARTIN A. BELL. The inheritance, interactions and linkage relations of genes causing yellow seedlings in maize. *Genetics* 15 (3): 253-282. 1930.—Reports two new lethal factors, L_2l_2 and L_4l_4, for yellow seedlings in maize which interact with other chlorophyll factors similarly to L_1l_1. No indications were found of linkage of L_3 with certain genes of the *R-G, B-Lg, Y-Pl*, and *Ra-Gl*$_1$ groups. Gene L_4 showed linkage with 3 genes of the *R-G* group, the order appearing to be L_4-*R*-W_2-L_2, with L_4 probably some 36 units to the left of *R*.—*F. D. Richey.*

9143. JONES, DONALD F. Dioecious maize. *Science* 73(1894): 432. 1931.—A recessive gene, silkless, makes the pistillate inflorescence of maize sterile, but does not affect the staminate inflorescence. Such plants are functionally males. Another recessive gene, tassel-seed, changes the terminal inflorescence from a pollen to a seed-bearing structure. These plants are functionally females. Crossing tassel-seed by silkless produced normal hermaphrodites. In later generations double recessive plants were obtained, indistinguishable in appearance from tassel-seed plants. These double recessive females when pollinated by males homozygous for silkless and heterozygous for tassel-seed produced progenies having male and female plants only, and the union of these two types is expected to give only male and female plants in following generations. In this way an hermaphroditic organism has been changed to a separate-sexed organism.—*D. F. Jones.*

9144. KELLY, J. P. Single and semi-double flowers in Phlox. *Jour. Heredity* 20(12): 549-554. 4 fig. 1929.—Three single-flowered varieties of *Phlox drummondii* were each crossed with the same type of semi-double *P. drummondii*. The F_1 groups varied. There was complete dominance of the single-flower in one type of family, i.e., no extra petals were seen. The second F_1 group comprised plants whose floral average was roughly one extra petal, while the third F_1 group was intermediate between single and semi-double, since its floral average showed about 2.5 extra petals. The effect of units for semi-doubleness varied according to the complex of genes accompanying the singleness or depended possibly on the kind of singleness met with. F_2 descendants from these F_1 groups indicated that semi-doubleness (i.e., 4 or 5 extra petals per flower) rests on two independent pairs of genes acting quantitatively. Some singles may carry inhibitors of doubleness.—*J. P. Kelly.*

9145. KIESSELBACH, T. A. The use of advanced generation hybrids as parents of double cross seed corn. *Jour. Amer. Soc. Agron.* 22(7): 614-626. 1930.—An improved method of producing double cross seed corn is described which greatly reduces the time and labor required without affecting the performance of the hybrids. Although the 2nd and 3rd generations of single crosses are significantly less productive than the 1st, F_1's of double crosses between 1st, 2nd, or 3rd generation single crosses were found to be essentially equal in yielding ability and in vegetative development. Use of this information in commercial production of double-cross seed corn permits great simplification of field technique. The proposed advanced-generation-parent method consists of producing but once in several years the two single crosses which serve as parents of the double-cross seed; and the use of a single seed plot for double-cross seed annually. The single crosses are planted in alternating blocks and one of the parents is detasseled before pollination. The detasseled plants provide the double-cross seed, and the tasseled plants produce advanced-generation seed of the single cross. Seed produced by the ♂ parent one year serves as the female parent the next, and this is mated with 2-year-old seed of the other hybrid parent. The basic selfed strains need be grown only in occasional years to produce a new supply of uncontaminated single-cross seed stock.—*H. B. Sprague.*

9146. KLEMM, M. Vergleichende morphologische und entwicklungsgeschichtliche Untersuchung einer Reihe multipler Allelomorphe bei Antirrhinum majus. [English summary.] *Bot. Arch.* 20(5/6): 423-474. 187 fig. 1927.—The morphology of flowers in all stages of development from primordia to maturity was studied comparatively in normal *A. majus*, in the *A. majus* mutants *chlorantha, nicotianoides*, and *globifera*, and in the hybrids *chlorantha nicotianoides, chlorantha globifera*, and *nicotianoides globifera*. The deviations from the normal development of sex organs which are found in normal plants are essentially different from those deviations found in the mutants of the allelomorphic lines here discussed. Deviations (phyllody, enlargement) appear most frequently in the shape of the 5th stamen (staminodium). The form of the fertile stamens is changed more rarely. In the formation of the gynecium no other changes could be perceived. Variations in the development of sex organs in these mutants occur chiefly in ♂ organs. These variations are initiated by the various mutants in quite different stages of their development. While some mutants develop nearly normal stamens, in others it was not possible to find even the primordium of sporogenous tissues. The ♀ organs become changed in a few cases only (*globifera, nicotianoides globifera*). The phenocritical phase (that is, the period in which differences between normal and abnormal flowers first become evident), is dependent on the character of the variation, and on the development of the organs which are subject to the variation:

in a complete metamorphosis of ♂ organs into ♀ ones, the phaenocritical phase occurs earlier than in partial variations; in the variation of vegetative blossom organs, it occurs as a rule much later than in a metamorphosis of generative ones. It is not a case of dominance of an hereditary factor over the others, but of a more or less perceptible surpassing of one factor over the other. The variations of the floral organs here described (especially the pistilloidy of the stamens) have been previously observed on other plants (*Papaver, Sempervivum*). The similarity of the pistilloid forms to those occurring in *Digitalis* is especially noteworthy.—*Author's summary.*

9147. **LESLEY, J. W. A few-seeded bud sport of tomato.** *Jour. Heredity* 20 (11) : 531-533. 3 fig. 1929.—Bud-variant branches of tomato were found having nearly seedless fruits of inferior size and eating quality, smaller glandular hairs and fewer long trichomes than the normal. Partial sterility of the variant was due, mainly, to defective female organs. The variant was a chimera, of which the subepidermal layer probably was unchanged, but fertility was affected by the presence of a variant epidermal layer.—*J. W. Lesley.*

9148. **MARSDEN-JONES, ERIC M. The genetics of Geum intermedium Willd. haud Ehrh., and its back-crosses.** *Jour. Genetics* 23 (3) : 377-395. 1 map. 4 pl. (1 col.). 1930.—A description is given of the wild collected plants used in the research. On crossing *Geum urbanum* with *rivale* a generation was obtained quite indistinguishable from natural hybrids observed in the wild. It was impossible to obtain viable seed when *rivale* was used as the seed parent. Although *G. intermedium,* the natural hybrid of *G. urbanum* and *G. rivale,* appears intermediate between its parents, it is not really so. Twelve characters were studied, 3 only were as in *intermedium,* 6 were dominant *rivale* characters, in 2 the *urbanum* characters appeared in the majority of plants, and in 1 there was loss of a character. Taking all characters into account *rivale* is the more dominant parent. On selfing *intermedium,* segregation took place, in many cases not conforming to simple Mendelian expectation. Four distinct types of plants appeared. On crossing *G. intermedium* with *rivale,* a generation was obtained in which the *rivale* characters strongly predominated, no distinct types stood out as in the F_2 generation from the selfing of *intermedium,* and the appearance of the plants in the beds gave the impression that they were a batch of *rivale.* No segregation took place comparable with that resulting from back-crossing of *intermedium* with *urbanum.* Two groups were made on petal shape, 10 plants having obovate and 30 oblate petals. *G. intermedium* × *urbanum* and the reciprocal gave identical results. There were 2 plants of *urbanum* and 2 of *intermedium,* the remainder were superficially very like *urbanum,* but analysis showed much segregation. A new character appeared, viz., short plumose hairs. A plant of back-cross origin, *G. intermedium* × *rivale,* was selfed, no segregation occurring, only minor fluctuations such as are found within the range of a species. A study was also made of a *Geum* population in a wood at Bradfield, Berkshire; and without the data obtained from the experimental work it would have been impossible to interpret the parentage of the plants aright. *G. urbanum, rivale* and all the possible combinations were found, but the chief interest lay in the fact that in the wet part of the wood which should have been the *rivale* habitat, comparatively few plants of this sp. were found, the predominant population being the back-cross *rivale* × *intermedium.* From the examination of this *Geum* population, it would appear that, in that locality at least, the back-cross has become stabilised and very largely replaced *rivale,* an example of a wild population of a new type arising from inter-specific hybridisation.—*E. M. Marsden-Jones.*

9149. **MICHAELIS, P. Zur Kenntnis einiger Digitalis-Bastarde.** *Biol. Centralbl.* 51 (3) : 124-134. 16 fig. 1931. —In crossing experiments with *Digitalis purpurea, lutea,* and *ambigua,* reciprocal crosses were successful between *purpurea* and *lutea* only. The hybrids were reciprocally different, and the degree of difference is dependent on environmental conditions mostly, but on the origin of the maternal *D. purpurea* plants also. The reciprocal differences in size and form of cotyledons are conditioned only by the size of seed of the maternal plants. The matroclinous "false hybrids" reported by Haase-Bessel are regarded as due to error. The diploid chromosome numbers are: *D. purpurea, ambigua,* and their hybrids, 56; *lutea,* 96; and the hybrids of *lutea,* 76.—*P. Michaelis (transl. by N. A. Pettinger).*

9150. **MUTH, HEINZ. Untersuchungen über die Befruchtungsverhältnisse bei Vicia sepium L. (Zaunwicke) und Lathyrus pratensis L. (Wiesenplatterbse).** *Zeitschr. Zücht. Reihe A, Pflanzenzücht.* 16 (3) : 465-504. 17 fig. 1931.—Seed of both species was obtained from an experimental field planted from the wild. *V. sepium* showed greater variation than *L. pratensis.* Both were easily propagated by rhizome cuttings and fairly so by slips in sand. Experiments in fertilization and seed production showed higher success from free-blooming, as compared with strictly guarded, plants, with guarded plants shaken daily, or with guarded plants artificially pollinated; this was especially true with *L. pratensis.* Among the various species of hymenopterous insect visitors, *Bombus terrestris* was perhaps most common. This bee tended to drive away other (pollen-gathering) insects; flowers were pierced and nectar secured illegitimately. Clones of the 2 species were given 5 treatments as to isolation and pollination. Individuals of *Bombus* were enclosed daily with isolated plants. Under free-blooming conditions of *V. sepium,* self-fertilization by means of insects is most common. Plants isolated with *Bombus* set less seed than when free-blooming; and this was true also when artificially cross-pollinated are compared with free-blooming plants. *L. pratensis* shows less inclination to self-fertility than *V. sepium.* Attempts made to cross *V. sepium* with other *Vicia* spp. were futile, as were similar attempts with *L. pratensis* and other *Lathyrus* species. Failure to cross was not due to faulty emasculation technique. Studies were made with *V. sepium* as to the relationship between seed setting and temperature and humidity. Plants were grown in the open and in cages variously screened. Fertile pods formed freely at a temperature of 14°C. but none set at 42.9°. In general, seed setting increased with a decrease of relative humidity although striking exceptions were found. Seed setting probably increased with decrease of absolute humidity. Self-fertilization in *V. sepium* did not result in decrease of vigor in the offspring, but such decrease did take place in *L. pratensis.* Seed setting in both is comparatively low. Possibilities of improvement in both seem excellent.—*L. R. Waldron.*

9151. **NEWTON, MARGARET, T. JOHNSON, and A. M. BROWN. A study of the inheritance of spore color and pathogenicity in crosses between physiologic forms of Puccinia graminis tritici.** *Sci. Agric.* [*Ottawa*] 10 (12) : 775-798. 1 pl., 2 fig. 1930.—Crosses were made between physiologic forms having abnormal colors. One with orange-colored urediniospores was crossed with 2 possessing grayish-brown urediniospores. The F_1 hybrids from both crosses were normal (red) in urediniospore color. The F_2 hybrids from one of the crosses were found to fall into 4 classes: red, greyish-brown, orange, and white. It is suggested, although not definitely proven, that two pairs of Mendelian factors determine this color inheritance. A study was made of inheritance of pathogenicity in these crosses. A cross between forms 9 and 36 produced an F_1 identified as form 17. 126 F_2 hybrids from this cross were identified as one or another of 7 physiologic forms, namely, 1, 11, 15, 17, 36, 57, and 85. Another cross, form 9 × form 15, produced F_1 hybrids identified as 9. F_2 hybrids from this cross were identified as forms 9, 15, 57, and 85. In many of the crosses, the inheritance of pathogenicity is governed by Mendelian factors. In some crosses, however, there is evidence that Mendelian, is supplemented by cytoplasmic, inheritance.—*T. Johnson.*

9152. NEWTON, W. C. F. Genetical experiments with Silene otites and related species. *Jour. Genetics* 24(1): 109-120. 1 pl., 1 fig. 1931.—When *Silene pseudotites* as ♀ parent is crossed to *S. otites* the F_1 consisted of 209 ♀♀, 4 ♂♂ and 4 hermaphrodites. The reciprocal cross gave a normal sex ratio of 1 ♂: 1 ♀. The F_2 of both crosses had an excess of males. No satisfactory hypothesis for the facts has been suggested. Both ♀ and ♂ parents carry a subsidiary factor for sex determination. Females of a similar origin give similar sex ratios with 1 ♂ and ♀♀ of dissimilar origin give dissimilar sex ratios. Different ♂♂ with 1 ♀ give different sex ratios. Reasons are given which indicate that the occurrence of intersexes depend on factors carried by *S. pseudotites*, perhaps by *S. umbellata* but not by *S. otites*.—*F. W. Sansome.*

9153. NOACK, KONRAD L. Über eine buntblättrige Form von Borrago officinalis. *Zeitschr. Indukt. Abstamm.- u. Vererbungsl.* 58(3/4): 372-392. 4 fig. 1931.—A description is given of a variegated *B. officinalis* the leaves of which are irregularly mottled with green and white up to the inflorescence, the degree of mottling being approximately uniform from the first foliage leaf to the flowers. The main mass of mesophyll consists of wholly green and wholly white cells intermingled with cells in which there are green and colorless plastids in all ratios. Both parents transmit the variegated patterns, and in their descendants varying numbers of green and variegated individuals appear. Pure white seedlings were not found. While the morphological observations and the results of selfing and crossing favor the plastid theory, the inconsistencies indicate that the origin of the variegations cannot be explained along these lines alone. It may be assumed that anomalies in the physiological exchange of materials may condition the observed appearances.—*Author's summary (transl. by I. Hein).*

9154. OEHLER, ERNST. Untersuchungen über Ansatzverhältnisse, Morphologie und Fertilität bei Weizen-Roggenbastarden. *Zeitschr. Zücht. Reihe A, Pflanzenzücht.* 16(3): 357-393. 20 fig. 1931.—The wheats used were mainly varieties of *Triticum vulgare*, although forms of *T. spelta, T. compactum, T. turgidum, T. durum, T. polonicum, T. dicoccum, T. monococcum* and *T. aegilopoides* were utilized. Various cultivated ryes were used and also forms of *Secale cereale, vulpinum* and *fuscum*. During the 3 years of the work, 807 emasculated heads of *Triticum* were used, a total of 21,290 florets were pollinated with rye pollen and 1494 seeds harvested. The plants were grown in pots, either in cages or in culture houses. The *vulpinum* and *fuscum* pollen was as effective as that from cultivated ryes. The hexaploid wheats were by far the most successful parents. Germination of the F_1 generally was very poor. Detailed measurements and observations are given of the 3 filial generations, particularly of F_1. In general, F_1 plants inclined toward the wheat parent, in accord with the greater wheat chromosome complex. The F_1 plants were evidently all completely self sterile; F_2 seeds were obtained by natural or artificial back crosses with wheat; those with rye were ineffective. Only 10 seeds were obtained by artificial back-crossing of 12,625 florets, or 0.08%. About the same % of seed was obtained when plants were exposed to natural back-crossing in the open. With continuous back-crossing, the hybrids approached the wheat standard in morphology and fertility.—*L. R. Waldron.*

9155. PEEBLES, ROBERT H. Hairy bolls and nectaries in a hybrid cotton. *Jour. Heredity* 20(7): 340-347. 7 fig. 1929.—Segregates from Pima Egyptian × College Upland crosses having intra-carpellary hairs are described. Apparently two factors are involved in the inheritance.—*L. M. Dickerson.*

9157. ROBINSON, T. RALPH, and GEO. M. DARROW. A pink Poinsettia chimera. *Jour. Heredity* 20(7): 335-339. 3 fig. 1929.—Results of root-cutting experiments on *Euphorbia pulcherrima* indicate that the pink form is a chimeral sport of red. White is apparently a mutation from red.—*L. M. Dickerson.*

9158. SIEGLINGER, JOHN B. Tenuous kaffir plants. *Jour. Heredity* 20(12): 565-566. 2 fig. 1929.—The occurrence and description of grass-like, or tenuous, plants in a cross of Sunrise and Red kaffir (*Holcus sorghum* (L.)) is noted. The condition appears to be caused by a single recessive factor. The defective plants produced no pollen or seed.—*J. B. Sieglinger.*

9159. STUBBE, HANS. Untersuchungen über die experimentelle Auslösung von Mutationen bei Antirrhinum Majus. II. (Samen- und Keimlingsbehandlung mit Röntgenstrahlen und Chemikalien.) *Zeitschr. Indukt. Abstammungs- u. Vererbungslehre* 56: 202-232. 1930.—Seeds and seedlings of *Antirrhinum majus*—Races 2232 ($pal_{rhod}del$) and 2249 ($pal_{tub}del$) were treated with x-rays of various strengths and with chemicals of different inorganic groups. As a result of the treatments, mutations appeared in the F_1 which differed widely from the spontaneous mutations hitherto recorded for these plants. The mutations manifested themselves as marked deformation of foliage. Phenotypically some of these resembled the "radiomorphoses" described by Miss Stein. The percentage of induced exceeded that of spontaneous mutations. Under certain conditions, especially treatment with arsenic preparations, mutations appeared in the parental generation in small percentage, but after treatment with most substances and with x-rays the mutations first appeared in F_1 and without plan or clear relation to strength of dose. Within each of the races, the same forms (in general) appeared, no matter what the treatment. "Crisp"-like plants appeared only in F_1, only after irradiation of the seeds with x-rays and only in race 2249, no matter what the dosage. There appears to be no specific effect of any one stimulus, but the reaction of each race is specific; that is, each race reacts with a new form characteristic for that form after any stimulus. No conclusion can be drawn from these results as to the nature of the mutations. Radiomorph-like plants with extreme crisping of leaves were peculiarly analogous to those having the albo-maculatio character. A few mutations appeared to be linked.—*C. S. Gager.*

9160. TSCHERMAK, E. von. Über Xenien bei Leguminosen. *Rept. & Proc. Internat. Hort. Congr. London* 9: 340-347. 1930.—Under xenia are distinguished: (a) seed-xenia, viz., patroclinal modification of the color, shape, size and chemical constitution; (b) Fruit-xenia, or vegetative effects of fertilization, viz., increase in growth rate of the pods, as well as patroclinal modifications of the shape and chemical constitution of fruit. The following cases of seed-xenia are described and discussed: (1) color-xenia in peas, beans (*Phaseolus vulgaris* and *P. multiflorus*), lentils, bitter vetches, vetches, lupins, rye, barley and stocks; size-xenia, which occurs in crosses between certain bean races but is lacking in other, similar crosses. (2) Fruit-xenia in wallflowers, beans, cucumbers and melons. Stress is laid on the practical value of color-xenia and seed heterogeneity as an index for certain other seed qualities (apparently orange color and good flavor in lentils, possibly light color and low degree of bitterness in vetches and lupins, and yellow color and high brewing value in winter barley) and as an indication of the occurrence of cross-fertilization in spp. usually regarded as self-fertilized. The occurrence of secondary, along with primary, segregation in seed-color is recorded, and attributed to polymeric differentiation in catalytic-cumulative factors acting with a chief color factor. In a cross between certain races of beans, one combination gave size-xenia and consequent seed-heterogeneity, the reciprocal an F_2 segregation into plants of different seed size, constant for each individual plant. In other kinds of beans, such a result was obtained in both cases. A distinction is drawn between independent and dependent inheritance of seed characters. The latter is attributed to internal secretory

subordination or to a chemical determining influence, in which case a substance, originating anywhere in the plant-body, spreads through the latter and compels the ovules to attain the shape and size typical of the race and to remain uninfluenced by foreign pollen.—*Author's summary.*

9161. WEATHERWAX, PAUL. The morphological nature of teopod corn. *Jour. Heredity* 20(7): 325-330. 4 fig. 1929.—The various characteristics of this unusual type of variation are described in detail. Apparently 6 constant morphological structures and at least 5 more variable characters are controlled by this single dominant gene complex.—*L. M. Dickerson.*

GENERAL

9163. CHOPARD, L. Aperçu sur la flore et la faune des Açores. *Compt. Rend. Som. Séances Soc. Biogéogr.* 65: 34-36. 1931.—The comparative poverty of the Azores islands in endemic spp., and the marked affinities with temperate European flora and fauna favor the hypothesis of a former connection between the Azores and Europe, before the eruptions at the end of the Miocene, rather than an oceanic origin of the biota.

9164. EWALD, KARL, (transl. from the Danish by HERMANN KIY). Tiere unter sich. 9th ed. 158p. Franckh'sche Verlag.: Stuttgart, 1929. Pr. 5.60 M.—This selection from the popular natural history writings of the Danish author Ewald deals with spiders, bacteria, life on marine piling, animal visitors to the pond, mistletoe, eider ducks, plant lice, and the life of forest and heath.—*C. A. Kofoid.*

9165. GARDINER, J. STANLEY. Photosynthesis and solution in formation of coral reefs. *Nature* [*London*] 127(3214): 857-858. 1931.—Two primary biological forces are at work shaping coral reefs: photosynthesis, which gives an extraordinary biological efficiency to the reef building organism and causes an incredible rapidity of formation of limestone; and the solution of limestone by boring organisms. A few seaweeds such as *Halimeda* with precipitated lime in their fronds assist in forming deposits, but the main reef-builders are about 12 spp. of 5 genera of Lithothamnioneae, which possess dense skeletons of lime in the composition of which Mg up to about 20% may play a part. The sedentary animal builders are all Coelenterates. The special difficulties in respect to the nutrition of the coral-building sedentary animals are met by the symbiotic relations with unicellular green flagellates (*Zooxanthellae*) which produce the O needed by the corals, and consume the waste N and CO_2 of the animals. The boring process and solution of the lime is carried on both by animals and boring algae.

9166. LLOYD, HOYES. Water and water-fowl. *Trans. 16th Amer. Game Conference* p. 122-127. 1930.—Remarks on the relation of sunspots to tree growth, rainfall, migration of birds, abundance of varying hares, etc.

9167. MARTONNE, EMMANUEL de. Conditions physiques du peuplement des hautes montagnes. [Physical conditions of the population of high mountains.] In: *Peuplement des Hautes Montagnes. Mém. Soc. Biogéogr.* [*Paris*] 2: 7-11. 1928.

9168. MATHIASSEN, THERKEL. Contributions to the physiography of Southampton Island. *Rept. 5th Thule Exped. 1921-24.* [*Copenhagen*] 1(2): 1-30. 3 maps, 3 fig. 1931.—This report contains brief preliminary accounts of the flora and fauna of the island (Canada, lat. about 62° 50′-66° N., long. 80-87° W.).

9169. PARKER, ERIC. English wild life. [*The English Heritage Series.*] 180p. Longmans, Green & Co.: New York, 1929.

9170. PEARSE, A. S. Environment and life. 85p. English +104p. Japanese. 1 fig. Ryobundo: Tokyo, 1930. Pr. $1.60; 117p. C. C. Thomas: Springfield, Illinois, 1930. Pr. $2.00.—This is a popular book containing 6 chapters on Animals and environment; Where animals live; Interdependence of plants and animals; Environment and evolution; Man and environment; and Science, commerce, and religion.—*A. S. Pearse.*

9171. PEARSE, A. S. The beaches at Misaki. *Jour. Pan-Pacific Res. Inst.* [*Honolulu*] 6(2): 3-6. 1931.—A general account of marine and maritime life about the Biological Station of the Univ. of Tokyo. Many spp. are mentioned, with notes on habits and habitats.

9172. THOMPSON, THOMAS G., ROBERT C. MILLER, GEORGE H. HITCHINGS, and SELDON P. TODD. Studies of the sea water near the Puget Sound Biological Station during the summer of 1927. *Publ. Puget Sound Biol. Sta.* 7(1): 65-99. Map, 1929.—An analytical study of tidal changes and interrelationships of certain physico-chemical conditions of sea water based on a series of hourly observations through a 25 hr. tidal cycle, and

supplemented by additional observations at flood and ebb tides at various localities in the San Juan Archipelago, showed that chlorinity, I number, temp., and pH are more or less correlated with tidal changes, while dissolved O and CO_2 are related primarily to rate of photosynthesis. In vertical section, surface to bottom, Cl and total CO_2 increase; while temp., dissolved O, and pH values decrease. Marked horizontal stratification occurs where sea water meets more dilute ebb water north of San Juan Island; at the surface a sharp line of demarcation of temp., chlorinity, CO_2, and pH was observed.—*H. B. Sewell.*

9173. **THOMSON, WALLACE A. The photo-electric measurement and photographic recording of daylight.** *Canadian Jour. Res.* 4(6): 559-564. 1931.—A method is described by which illumination intensities were measured by a photo-electric cell and galvanometer, and a continuous photographic record obtained of the variations of intensity over a period of time during which the ground was covered with snow. A remarkable increase in the illumination was caused by the presence of cloudiness with full sunshine, in many cases 20-30% and on one occasion as high as 40%. When there was a cloud over the sun, with most of the sky clear, the decrease in illumination varied up to 35%, depending on the density of the cloud, and on many occasions the increase in indirect illumination due to overhead cloudiness more than balanced the decrease of direct illumination when the sun was partly hidden. It is concluded that the intensity may be greater with the sun partly hidden than at the same time of day with a clear sky.—*Author's summary.*

9174. **WARDLAW, H. S. HALCRO. Some aspects of the adaptation of living organisms to their environment.** *Proc. Linnean Soc. N. S. Wales* 55(1): i-xxv. 1930.—This presidential address is preceded by a review of the work of the Society during the yr. and brief sketches of the lives of Prof. Walter Baldwin Spencer [1860-1929], biologist and anthropologist; and Arthur Andrew Hamilton [1855-1929], botanist and horticulturist.

ANIMAL

9175. **ALLARD, H. A. The chirping rates of the snowy tree cricket (Oecanthus niveus) as affected by external conditions.** *Canadian Ent.* 62(6): 131-142. 3 fig. 1930.—The history of the studies correlating the synchronous chirping of the crickets with temp. are reviewed. Original records corroborate earlier statements of increase of chirps per min. with increase of temp. at 55-70° F, and also show a slight correlation with increased humidity at 80-95%; but there are too many unsolved factors to permit the statement of a definite correlation factor.

9176. **ALLARD, H. A. The photoperiodism of the firefly Photinus pyralis Linn.; its relation to the evening twilight and other conditions.** *Proc. Ent. Soc. Washington* 33(3): 49-58. 1 fig. 1931.—Observations made from June 13th to Aug. 7th on the time of appearance of fire flies in the evening are correlated with open and shaded places, wind velocity, ground conditions, air temp. at grass level, and relative humidity. A distinct correlation is observed between time of arising and time of sunset. In the open or clear nights they rise 8.7 min. after sunset and in the shade 2.8 min. before sunset.

9177. **ALLEE, W. C. Animal aggregations. A study in general sociology.** 431p. 35 fig. Univ. of Chicago Press: Chicago, 1931. Pr. $5.—The book contains 20 chapters which are organized in 5 groups. The first 5 chapters, included under "Introduction," are largely theoretical and treat of the philosophy of classifying animal aggregations, the causes of their formation, and the general conditions obtaining in them. The next 3 chapters are grouped as "Harmful effects of aggregations" and treat of the effects of crowding upon growth; the retarding influence on the rate of reproduction; and the increased death rate. The 3rd group of chapters (IX-XVI), "The beneficial effects of aggregations," treats of the stimulation of growth; stimulation of rate of reproduction; effect of crowding on survival and O consumption; protection from toxic reagents; resistance to hypotonic seawater; relation between density of population and insect survival; communal activity of bacteria; and mass physiology of spermatozoa. The 4th group, "General effects of aggregations," treats of the influence of crowding upon sex determination; and of the morphological effects of crowding. The last 2 chapters (XIX and XX) are grouped under the heading "Conclusion" and are essentially philosophical; they treat of the animal aggregations and social life, and of the principles of co-operation.—*R. N. Chapman.*

9178. **ANDREWS, E. A. The mound-building ant, Formica exsectoides F., associated with tree-hoppers.** *Ann. Ent. Soc. Amer.* 22(3): 369-391. 5 fig. 1929.—Near Baltimore the ant feeds on living and dead insects and on honey-dew excreted not only by aphids but by coccids and membracids. Food associations are formed with *Eulecanium tulipiferum* on *Liriodendron tulipifera* and with *Vanduzea aquata* and *Thelia bimaculata* on *Robinia pseudacacia*. The membracids, chiefly when young, supply to the ants acid honey-dew from May into Oct., being attended day and night by them. The tree hoppers seem remarkably inert to the presence of the ants and make no exertion to gain their attention; they may live in the absence of ants and then cast off honey-dew with greater effort and more force. Rate of flow is increased by the presence of ants. It is suggested that the primary influence of membracids upon the ant is through some sort of skin exudation. Succursals made by the ants at the bases of small trees when used by *Thelia* are roofed over by the ants as tents that protect and to some extent limit the freedom of the young *Thelia* for a time. Ants attempt to maintain a monopoly of the tree-hopper honey-dew but several sugar flies obtain some by avoiding the ants: *Callopostromyia annulipes* licks up honey-dew that has fallen; *Rivellia quadrifasciata* drums very rapidly with the front legs before taking off honey-dew from the *Thelia* larvae.—*M. W. Boesel.*

9179. **ARTHUR, STANLEY C. Winter requirements of migratory waterfowl.** *Trans. 16th Am. Game Conference* 98-102. 1930.—Louisiana marsh lands that are left in a natural condition for the production of muskrats form some of the most important wintering grounds in the U. S. A. for ducks and geese.

9180. **BOWEN, EZRA. An hypothesis of population growth.** 238p. Columbia Univ. Press: New York; P. S. King & Son: London, 1931.—The book supports the thesis that the main forces operating upon the growth of human populations are wealth and living standards. The chapter headings are: A formula ("Populations tend to increase, directly with wealth, and inversely with prevailing levels of living standards"); Malthus, a revaluation; Critics of Malthus; The theories of East and Pearl; Other post-war theories; The life "struggle"—man appears; The struggle continues; Animal increase; Biology of population growth; Death rates; Migration; Birth rates; The dysgenic trend; In sum; In prospect.—*C. S. Gager.*

9181. **FOSBERG, F. RAYMOND. Preliminary notes on the fauna of the giant kelp.** *Jour. Ent. & Zool.* 21(4): 133-135. 1 fig. 1929.—The most interesting clinging animals found were the nudibranch, *Melibe leonina* Gould, and some isopods not yet determined.—*W. A. Hilton.*

9182. **GUNN, D. L. Temperature and humidity relations of the cockroach.** *Nature [London]* 128(3222): 186-187. 1931.—The cockroach loses water at a rate proportional to the drying power of the air. At 30° C. in dry air they lose daily an average amount of water equal to about 9% of their original wt. With reduction of % of water in the body, the roach goes toward lower temp.

9183. **HANDSCHIN, EDUARD. Die Temperatur als Faktor lokaler Tierwanderung im Boden.** *Verhandl. Naturforsch. Ges. Basel* 40(2): 486-504. 5 fig. 1929.—Experiments in an apparatus producing a temp. gradient in a column of soil 2-4 cm. thick showed that soil animals migrate from a region of 30° or above to one of 26-30°.

The migrants tend to congregate at this temp. Low temp. limit activity and hence migration; 26-30° is considered optimal. Daily and seasonal soil temp. changes cause vertical migrations. *Lumbricus terrestri* and Enchytraeidae were some of the forms used.—*G. W. Goldsmith.*

9184. **HENDRICKSON, GEORGE O. Subterranean insects of marsh grass (Spartina michauxiana Hitchcock).** *Canadian Ent.* 63(5): 109-110. 1931.—From 15 sq. ft. of sod, 8 in. deep, were collected 1 sp. of Neuroptera, 2 Orthoptera, 2 Homoptera, 13 Coleoptera, and 8 Hymenoptera.

9185. **JACOT, ARTHUR PAUL. Zoögeographical status of the North China plain.** *Peking Nat. Hist. Bull.* 5(3): 41-44. 1931.—The distribution of various amphibians and reptiles in this region shows that (in agreement with R. Mell) the Tsinling-Funiu Shan range is the divide between the Shansian and the Yangtzian life zones. Mell made the Yellow River the eastern boundary, but since the entire North China plain is the delta of this river, the boundary should be considered as the fringe of the Chili hills.

9186. **[KASHKAROV, D. N.]** КАШКАРОВ, Д. Н. Метод количественного изучения фауны позвоночных и анализа полученных данных. **[The quantitative method in the field study of vertebrate fauna and analysis of the data obtained.]** [English summary.] Труды Средне-Азиатского Государственного Университета, Сер. VIII-a. Зоол. (*Acta Univ. Asiae Mediae, Ser. VIII-a. Zool.*) 1. 3-24. 1927.—Principles are given for quantitative census of animals found in a given area. The unit of study is the association, which is broken up into smaller areas. The number of each sp. listed and its frequency with respect to other sp. and locality as well as its adaptation are determined. The association is then studied; its coefficient of community and the number of constant, usual, and accidental sp. are considered. This method of study is useful for ecological and genetical analysis.—*B. R. Weimer.*

9187. **KRÜGER, E. Ein Beitrag zur Mimikryfrage.** *Ent. Rundschau* 47(4): 13-14; (5): 17-19; (6): 22-24; (7): 27-28. 1 fig. 1930.—Studies in insect mimicry.

9188. **MacDONALD, RODERICK. The form of faecal pellets and specific identification.** *Nature* [*London*] 128(3219): 68. 1931.—By a special apparatus a bottom sampler withdraws a core of mud from the sea bottom. There is a distinct stratification in this core of identifiable fecal pellets derived from different sp., making possible a history of the nature of population in a specific area over a period.

9189. **MARTINI, E., und I. ACHUNDOW. Versuche über Farbenanpassung bei Culiciden.** *Zool. Anz.* 81 (1/4): 25-44. 7 fig. 1929.—The larvae of *Anopheles maculipennis, A. bifurcatus, Theobaldia annulata, Aëdes salinus,* and *Culex pipiens* reared in black or brown vessels are darker than those reared in green, white, or gray vessels. This difference is also noticeable in the early pupa and in the imago. *Corethra* larvae reared in a dark vessel are smoky colored, the pigment cells on the air sacs are fairly broad; 4-, 5-, or 6-angular cells cover the entire air sac. Larvae reared in white vessels appear a bright glassy color, and the pigment cells on the air sacs appear as small black pigmented granules and as pigment clumps. The head (except for the occiput, the teeth of the mandibles, and eyes) does not contain pigment cells. Changing the larvae from a black to a white vessel, and vice versa, results in a rapid redistribution of pigment cells. *Corethra* pupae also show color differences. The ♀ adult from a dark vessel has a darker dorsal surface, while the ♂♂ are dark from both vessels. The brain appears to play a part in this adaptation.—*D. Ludwig.*

9190. **MELL, R. Leitgedanken zu einer Ökologie südchinesischer Lepidopteren.** *Congrès Internat. Xe Zool. à Budapest 1927. Part 2.* 1053-1059. 1929.—Holo-arctic, Pacific-palaearctic, Indo-Malayan, Indo-Ethiopian, and eastern Himalayan elements are recognized. The number of generations in these respective groups; prevailing rhythm in the cycle of their development, i.e., whether continuous, alternating, or fractionary (where the development of a single individual of the same generation is accelerated or retarded); color of caterpillars; sculpture of tegument of pupae; physiological energy of the sexes in a case of decreased numbers of individuals, i.e., the predominance of one sex over the other; time of emergence and flying period; production of eggs; progressive and regressive development of morphological, physiological, and sensitive characters; the ability of the Lepidoptera to react to meteorological factors; and the fluctuation of sp. at the boundary of their habitats are also considered.—*C. Zeimet.*

9191. **SAVAGE, R. E. The influence of Phaeocystis on the migrations of the herring.** *Min. Agric. and Fish., Fishery Invest. Ser. 2* 12(2): 5-14. 4 fig. 1930.—Variations in amounts of herring expected on fishing grounds, or occurrence in unusual locations, caused investigations to be made to ascertain if any unusual distribution of the plankton might be correlated with these movements. Large areas of a gelatinous, colonial flagellate, *P. poucheti,* were discovered, in such amounts and position that they probably formed effective barriers to the movements of the migrating herring schools, and hence caused deflections of their courses. Position and extent of these *Phaeocystis* areas were determined by qualitative studies, and were plotted on charts, upon which also were indicated the probable course of herring migrations. These data supply most suggestive explanations for the observed phenomena.—*R. H. M'Gonigle.*

9192. **SCHADE, FR. Im Quellgebiet des Monday. [At the sources of the Rio Monday, Paraguay.]** *Ent. Rundschau* 47(2): 6-7; (3): 12; (4): 16. 1930.—Observations of insect and other animal life.

9193. **SKWARRA, ELISABETH. Die Ameisenfauna des Zehlaubruches.** *Schriften Phys.-ökon. Ges. Königsberg i. Pr.* 66(2): 3-174. 2 pl., 12 fig. 1929.—This monograph comprises a study of the ants of living sphagnum bogs and their vicinity. The distribution of the faunistically interesting sp. *Formica fusca-picea* Nyl and *F. uralensis* Ruzsky was established; in Siberia both inhabit the Steppes, but westward they become high moor sp. On the basis of distribution of ant sp., they can be divided into those absent from, those invading, and those limited to the bog habitat. The last 3 chapters deal with the nest ecology of the bog ants (similar terrains show a certain uniformity of nest structure), the methods of hibernation, and the relatively few inquilines found in the ant nests. An extensive bibliography is appended.—*E. Skwarra* (*transl. by H. G. Good*).

9194. **STADLER, HANS. Vorschläge zur zweckmässigen und einheitlichen Gestaltung örtlicher Avifaunen, erläutert an Beispielen aus der Vogelwelt Unterfrankens. Ein Wort an die Avifaunen schreibenden Zeitgenossen.** *Verhandl. Ornith. Ges. Bayern* 19(1): 110-148. 7 maps. 1930.—The treatment of local avifauna from an ecological point of view is suggested: the division of the whole area into its ecological subdivisions, with an account of other vertebrates and also invertebrates found in each; a discussion of climate and geological conditions, of changes in the fauna due to man or to other causes, and of distributional limits of various sp.; and a detailed account of migration. Finally, a systematic account of the sp. is indispensable. Numerous examples of this method of treatment are drawn from an area in the Main Valley of northern Bavaria.

9195. **SUNDSTROM, KURT-ERIK. Ökologisch-geographische Studien über die Vogelfauna der Gegend von Ekanäs [Finland].** *Acta Zool. Fennica* 3: 1-170. 17 maps, Portrait, 13 pl. 1927.—This paper is prefaced with an anonymous biographical sketch of the author (1900-1925) and a portrait. The 1st part includes a discussion of ecological factors and methods of determining the numbers of individuals of the bird fauna; a description of the area investigated (a portion of the reef-dotted coast of southwestern Finland) and of the 5 ecological

subdivisions of this area; and a review of previous work on the local avifauna. The systematic account treats of 179 sp., of which 116 were nesting; it includes technical and Swedish names, and notes on geographical and ecological distribution, frequency, details of nesting, song, migration, and general habits. Maps indicate the local distribution and frequency of many breeding sp. Censuses are given of the breeding birds of 25 selected areas of limited extent. Tables show the estimated bird population of the whole area (about 1000 sq. km.) by sp.; of the total of about 25,000 pairs, there are 10,000 pairs of *Fringilla coelebs*; 1,500 of *Phyllo-scopus trochilus*; and 700 each of *Sturnus vulgaris*, *Emberiza citrinella*, and *Turdus pilaris*.

9196. THOMAS, C. A. The predatory enemies of Elateridae (Coleoptera). *Ent. News* 42(5): 137-140; (6): 158-167. 1931.—This is a compilation of recorded predators on Elateridae, including Acarina, Pseudoscorpionida, Araneida, Hemiptera, Homoptera, Coleoptera, Diptera, amphibia, lizards, birds, and mammals. The bibliography contains 70 references.

9197. THOMPSON, WARREN S. Ratio of children to women, 1920. A study in the differential rate of natural increase in the United States. 242p. U. S. Government Printing Office: Washington, D. C. 1931.—This study throws light on the differential rates of increase in the city and the country, and the differences in contribution to population growth between the native and foreign born. On the whole, foreign born women have higher ratios of children than native women. In 1870, 19.9% of the population was 40 yrs. of age and over; and in 1920, 26.9% of the population was in this age group. A continuation of this trend will result in an age constitution approximating that of a stationary population. Whereas the 1920 ratios of children to women are in excess of "temporary replacement" needs among both native white and foreign born white women, but particularly among the latter, they are deficient for "permanent replacement" needs among the native white women (except in rural parts of the country). In the light of the increasing restriction upon immigration, the higher average age of the population, etc., it appears probable that population growth will show a rapid decline in the near future, and will become stationary within a few decades.—*W. S. Thompson.*

9199. UVAROV, B. P. Insects and climate. *Trans. Ent. Soc.* [*London*] 79(1): 1-247. 53 fig. 1931.—Data culled from over 1150 papers are presented on the influence of climatic factors on insects. Investigators interested in insect epidemiology should pay more attention to climatic factors and less to biotic relationships. Physiological studies in the laboratory are the basis for practical investigations in the field. The 1st part is a summary of such studies. The 2nd part contains a survey of the facts relating to the influence on insects of the natural climatic environment. A discussion of temp. occupies most of the 1st section, with shorter divisions on humidity, light, and atmospheric pressure. While an increase in temp. shortens the length of development, up to a certain point, a short exposure to temp. below developmental zero may have the same effect. Those who aim to express the relation between temp. and development by very exact formulae should not base their speculations on external temp., since these may differ considerably from the body temp. of the insects, and that difference is not constant. The 2nd section begins with weather and the activities of insects. Such examples are cited as the mass migration of locusts at high temp., the increase in the population of the herb stratum after a rain, and the influence of wind on the flight of insects. As to the cyclical phenomena, it is shown that the daily activities of the insects are directly dependent on the daily rhythm of the weather, and that they are to be explained not by any one factor but by combinations of several meteorological factors. Seasonal cycles, and the problems of diapauses, are discussed in detail. Moisture is of great importance in hibernation, and of governing importance in aestivation. Climate affects distribution and abundance. Wind is important in dispersal. Temp. affects dispersal through its effect on activity, and may also be a limiting factor, more at lower ranges than high. Temp. and humidity are much more important than any other factors in limiting distributions; ecoclimates and microclimates are more important than general meteorological conditions. Data on the control of numbers by climatic factors show that destruction of a high % of insects occurs at a given stage; the stage and governing factors vary greatly in different sp. The commonly accepted theory that fluctuations in numbers of insects are regulated by interrelation between the insect and its natural enemies, and that there is stable equilibrium, is severely criticised. Forecasts of outbreaks should be based on a thorough understanding of the physiological responses of the insect and the environmental factors to which it may be subjected. Control methods may be phenological, ecoclimatic, and by direct utilization of climatic factors.—*G. Shaw.*

9200. WARDLE, ROBERT A. Significant variables in the blowfly environment. *Ann. Appl. Biol.* 17(3): 554-574. 1930.—The environmental factors affecting the development of the blowfly, *Lucilia sericata*, include those which influence the biotic potential and the length of the developmental stages; those which influence the biotic potential but not the length of the stages; and those which influence behavior only. During the pre-imaginal stages of the insect, atmospheric and soil temp. outside the range 30-37° C. are of greatest importance. Relative atmospheric humidity values outside the range 90-100% and soil moisture content outside the range 40-60% are effective only during the season of adult activity. During the hibernation or aestivation period these values are 10-30° C. for temp., and 40-60% for soil moisture. Next to these factors in importance is the ratio between ♀ population and oviposition. Parasites and predators are less important factors. Formulae expressing the developmental rates for the different developmental stages of the insect separately and for the same stages taken as a unit, are presented; that for the entire pre-imaginal period is $y = 100/0.3x - 1.6$, where y denotes the length of the period and x the temp. Threshold temp., indicated by the reciprocals of the developmental curves, agree with the observations except in case of eggs above 14° C., where the indicated threshold is 9.5° C., obviously too high. A suggested explanation is that the velocity of development at this temp. is accelerated by the increased mass of atmospheric moisture per unit of saturated air.—*L. M. Peairs.*

DISEASES CAUSED BY FUNGI

9201. **BERGAMASCHI.** Une nouvelle maladie des fruits du prunier. *Soc. Internaz. Microbiol. Boll. Sez. Italiana* 3(1): 25-26. 1931.—Preliminary report on *Microstroma tonellianum* causing a disease of fruits of *Prunus domestica.*

9202. **CARON, OMER.** The cucumber gall. *Ann. Rept. Quebec Soc. Protect. Pl.* 20(1927-1928): 69-70. 1928. [French version: *Rapport Ann. Soc. Québec Protect. Pl.* 20(1927-1928): 73-74. 1928.]—*Cladosporium cucumerinum,* first noted at Sorel, Quebec, in 1925, is inconspicuous on the leaves, but on the stems and young fruit dark spots with drops of a viscous fluid are formed, later becoming whitish and then green, due to the sporulation of the fungus. The organism has been obtained in pure culture and successful inoculations made.—*W. A. Whitney.*

9203. **HOPKINS, J. C. F.** A Phytophthora from Antirrhinum causing a stem rot of tobacco. *Proc. Rhodesia Sci. Assoc.* 30: 49-52. 1930/1931.—Cultivated *Antirrhinum* in Rhodesia is attacked by *P. parasitica,* causing collar rot and wilt. Experimental infection of tobacco was obtained. This is believed to be the first record of the fungus on *Antirrhinum.*

9204. **IKATA, SUEHIKO, and TSUYOSHI HITOMI.** A new leaf-blight disease of the grape-vine. [In Japanese, with English summary.] *Ann. Phytopath. Soc. Japan* 2(4): 357-373. 2 pl. 1931.—The disease and its causal fungus, *Acrospermum* viticola* (p. 372), are briefly described. The conidial stage belongs to the genus *Spondylocladium* on *Acrothecium.* On culture media the fungus grows well, constantly producing conidia; perithecia have never been found. By artificial inoculations with conidia or ascospores, infection is obtained on American varieties (*Vitis labrusca*) but not on European varieties (*V. vinifera*). Incubation period is about 15-20 days from inoculations with ascospores, 15-16 days in the case of conidia. Infection results only when the under leaf surface is inoculated. Penetration is through stomata by means of germ-tubes. The primary infection is perhaps solely due to ascospores, because the conidia do not survive beyond May. Production of perithecia begins in November, a sclerotioid body first being formed; ascospores are formed in June-July. Optimum growth of the fungus is at 20-25° C.—*Authors' résumé.*

9205. **LIESE.** Starke Schäden durch den Pappelkrebs. *Deutsche Forstzeitg.* 46(19): 465-466. 2 fig. 1931.—Canadian poplar in western Westphalia recently suffered extensive damage by *Nectria coccinea* var. *sanguinella,* and probably also by *N. galligena* var. *major.* This wound parasite is characterized by an unusually rapid development of cankers, which appear even on 2-3-yr. old twigs.—*W. N. Sparhawk.*

9206. **MAIRE, R.** Algeria: Rhizoctonia medicaginis. *Internat. Bull. Plant Protect.* 5(7): 113. 1931.—Disease on lucerne new to north Africa.

9207. **MENDIOLA, VICTORIA B.** The Fusarium disease of corn. *Philippine Agric.* 19(2): 79-106. 2 pl., 1 fig. 1930.—A summary of this disease of maize caused by *F. moniliforme,* with special reference to its history in the Philippine Is.

9208. **MULLER, H. R. A.** Voorloopige mededeeling over een schimmel, geïsoleerd uit instervende koffieboomen in Zuid-Sumatra. [A mold isolated from coffee trees in south Sumatra.] *Arch. Koffiecult. Nederlandsch-Indië* 3(3): 167-181. 7 fig. 1929.—A fungus was consistently isolated from coffee trees infected by the "top disease" as well as from trees attacked by a die-back disease. The latter malady affects the branches of older trees, but shows much resemblance to the top disease of young trees. The identity of the fungus isolated from young trees with that obtained from old trees indicates the probability of the 2 diseases having a common cause. No fructifications of the fungus have been seen, but from the mycelial characteristics it belongs to the genus *Rhizoctonia.—From author's summary.*

9209. **ZÖHRER, FRIEDRICH.** Die Schäden durch Holzrücken im Hochgebirge. *Forstwiss. Centralbl.* 53 (14): 481-498. 1931.—In getting logs out of thinned or partially-cut stands in the mountains many of the standing trees are wounded, and most of these are later attacked by fungi. The rate of vertical and horizontal spread of rot in several hundred spruce trees was investigated and correlated with crown classes and age of the wounds. The average vertical spread ranged from 16.4 cm. a year in suppressed trees to 22.5 cm. in dominants, and the horizontal spread ranged from 8.5 sq. cm. a year in suppressed trees to 17.6 sq. cm. in dominants.—*W. N. Sparhawk.*

DISEASES CAUSED BY BACTERIA

9210. **FOSTER, W. R.** Bacterial fruit blight of the loganberry. *Scientific Agric.* 11(8): 529-534. 5 fig. 1931.—For a number of years, a blight of the immature fruits of the loganberry caused considerable loss in British Columbia, especially in 1930. In many of the fields 50-80% of the fruits were blighted. The symptoms are a necrosis or a desiccated condition of the fruit. A bacterial organism was isolated and its pathogenicity proved by inoculation and re-isolation in the field and in the laboratory. The same organism was also isolated from the wild blackberry and thimbleberry. When immature fruits of the raspberry and thimbleberry were artificially inoculated, typical symptoms developed. The organism has the S. A. B. index number 5210, 32100, 1000. and has been named *Bacillus* desiccans* (p. 533).—*From author's summary.*

9211. **REID, D. W.** The diagnosis of fireblight in New Zealand. *New Zealand Jour. Sci. and Tech.* 12(3): 166-172. Map, 2 fig. 1930.—This discusses the distribution in New Zealand, symptomatology, morphology, and cultural relations of the causal organism, which is a peritrichiate rod, differing somewhat in size, number of flagella, and rate of gelatin liquefaction, from *Bacillus amylovorus* as currently described in the U. S. A. *Eriobotrya japonica* (loquat) and *Pyracantha angustifolia* are new hosts.

DISEASES CAUSED BY ANIMAL PARASITES (INSECTS, NEMAS, PROTOZOANS, ETC.)

9212. **FUKUSHI, TEIKICHI, and HIDESAKU SAITO.** Angular leaf spot of Zinnia elegans Jacq. caused by eelworms. (Preliminary report.) *Tottori Nōgaku-Kwaihō (Trans. Tottori Soc. Agric. Sci.)* 2(1): 45-56. 1 pl. 1930.—This new disease, characterized by brown angular leaf spots bounded by small veins, occurs in the Province of Inaba and is caused by *Aphelenchus ritzema-bosi,* the chrysanthemum nematode, which also affects *Phlox drummondii* and *Dahlia cariabilis* in other countries. When artificially inoculated, it readily infests healthy

leaves of *Zinnia* and *Dahlia* and multiplies in the affected tissues. Results of inoculation experiments on chrysanthemum leaves are inconclusive, although a few naturally infested chrysanthemums were found growing near the affected zinnias.—*Authors' summary.*

9213. MARTIN, W. H. Brown ring disease of the sweet potato. *U. S. Dept. Agric. Bur. Plant. Indust. Plant Dis. Reptr.* 15(5): 41-42. 1931.—Summary of the disease, caused by *Tylenchus dipsaci*, as it has occurred in New Jersey since 1929.—*W. A. Whitney.*

9214. STEINER, G. Tylenchus dipsaci, the bulb or stem nema parasitizing strawberry plants in North Carolina. *U. S. Dept. Agric. Bur. Plant Indust. Plant Dis. Reptr.* 15(5): 42. 1931.—Records briefly the occurrence of a stem and fruit fasciation instead of the customary symptoms.—*W. A. Whitney.*

9215. STEINER, G. Rhabditis lambdiensis Maupas associated with a disease of mushrooms. *U. S. Dept. Agric. Bur. Plant Indust. Plant Dis. Reptr.* 15(5): 43. 1931.—This nema, associated with a pileus decay, is thought to carry decay-producing bacteria (perhaps *Bacterium tolaasi*) during sprinkling periods, and not to have any primary relation to the disease.—*W. A. Whitney.*

NON-PARASITIC DISEASES AND TERATOLOGY (INCLUDING DISEASES OF UNKNOWN CAUSE)

9216. FISHER, D. F., C. P. HARLEY, and CHARLES BROOKS. The influence of temperature on the development of watercore. *Proc. Amer. Soc. Hort. Sci.* 27: 276-280. 1930(1931).—Watercore of apples is a result of premature and non-uniform starch conversion that may be induced by the effect of comparatively high temp. on diastatic activity. High soluble sugar concentrations resulting from this hydrolysis apparently set up abnormal osmotic relationships, resulting in the guttation of the affected tissues with water.—*Authors' conclusion.*

9217. KOMURO, HIDEO. Über die Gewebeabnormität infolge von Riesenkern- und Riesenzellentstehung durch Tauchung in Kohlenteerlösung bei Pisum sativum-Wurzelspitze. [Tissue abnormality in consequence of the initiation of giant nuclei and giant cells by immersion of pea root tips in aqueous tar extract.] *Proc. Imp. Acad. [Tokyo]* 6(9): 375-378. 3 fig. 1930.

9218. [PINEVICH, L. M.] ПИНЕВИЧ, Л. М. Исследования над хлорозом табачных растений. [Chlorosis of tobacco.] Труды Детскосельской Акклиматизационной Станции при Ленинградском Сельско-Хозяйственном Институте. (*Bull. Sta. Acclim. Leningrad Agric. Inst. Detskoe Selo*) 4. 55-92. 8 fig. 1927.—In the experiments reported unavailability of Fe was the cause of chlorosis, and this disappeared when the plants were placed in an aqueous sol. of Fe salt. With distilled water favorable results were obtained when Fe was given in the form of ferric citrate, whereas with $FeCl_3$ the plants died, possibly because of excessive acidity. With Detskoje Selo tap water, which is rich in carbonates of Ca, good results were obtained with all the sources of Fe used. In the presence of carbonates of Ca, the solution of Fe salts is neutral or slightly alkaline, and the disappearance of chlorosis may be ascribed rather to the influence of Fe than to the acidity of the solution. The disappearance of chlorosis even when the reaction is slightly alkaline may be explained by the delayed hydrolysis of the Fe salts. In a solution of Fe salts in distilled water made alkaline by addition of NaOH up to pH 9.6, Fe may be discovered in the filtrate for many hours, the pH constantly decreasing. Plants that have recovered from chlorosis are again affected if transferred to neutral or alkaline Knop's solution. Chlorosis develops in alkaline Knop's solution and disappears when the solution is acid. In solutions of the same pH, the precipitation of Fe is considerably slower with Fe dissolved in water than in a complete nutrient solution. Chlorosis appears in plants grown in Knop's solution containing $CaCO_3$. The harmful influence of Ca carbonates is in direct proportion to their alkalinity and their buffer action, which maintains the solution at a more or less constant alkaline pH. The elimination of phosphates from a nutrient solution prepared with boiled water with the addition of $CaCO_3$ also induces chlorosis. Fe can not be found in an alkaline solution, containing soluble phosphates and Ca salts, but by eliminating one of these 2 components, Fe may be detected even in an alkaline solution for several hours. In Knop's solution made alkaline either by adding NaOH or $CaCO_3$ a colloidal precipitate of Ca phosphate is formed and removes dissolved iron. The decay and injury of the roots considered by some authors as the principal cause of chlorosis is not an essential condition, and there is no direct connection between the 2 phenomena. Often plants attacked by chlorosis possessed healthy roots, but in an acid reaction the plants remained green, even when the roots rotted severely.—*From author's summary.*

9219. SCHMIDT, ROBERT. Lettuce tipburn studies. *Proc. Ann. Convention Assoc. So. Agric. Workers [U. S. A.]* 31: 298-304. 1930.—In 1925 the heaviest injury occurred on the stiffer soils. Tipburn injury was not visibly influenced by fertilizer combinations, top dressings, organic or mineral nitrogen, or method of planting, except where growth was retarded, in which case the injury was less. Irrigation increased tipburn injury. Tipburn was severe in dense shade. The greatest injury occurred in periods of low evaporation immediately following periods of high evaporation. It is evident that field control of lettuce tipburn by cultural methods or fertilization is impossible. Injury can be reduced by methods which retard growth; but since this also gives a head of poorer quality, it is not desirable.—*Author's conclusions.*

INFECTIOUS CHLOROSES (MOSAIC, YELLOWS, CURL, ROSETTE, ETC.)

9220. DUFRÉNOY, JEAN. Condition d'hypotonie des cellules affectées par la mosaïque. *Compt. Rend. Soc. Biol.* 98(17): 1499-1500. 2 fig. 1928.—Neutral red in 9% sugar solution is isotonic with the affected cells in mosaic diseases (of *Sida, Phytolacca,* celery), confirming their hypotonicity.

9221. FOLSOM, DONALD. Virus diseases of the potato. *Proc. Ann. Meet. Potato Assoc. America* 17: 83-101. 1930(1931).—A review of work done in the U. S. A. and Europe, principally from 1928-1930. A long bibliography is given.

9222. SMITH, KENNETH M. Composite nature of certain potato viruses of the mosaic group. *Nature [London]* 127(3210): 702. 1931.—Recognizing that there are several virus diseases of potato which may be present together, leading to complexity of the diseases produced, 3 techniques for their separation are outlined: (1) utilization of the selective relationship between the aphis vector (*Myzus persicae*) and the tobacco plant; (2) by use of "filter" plants, e.g., by passage of a mixed virus through a plant susceptible to one of its components and immune to others; and (3) by taking advantage of the unequal rates of movement of the constituent viruses within the plant host.

9223. STOREY, H. H. A new virus disease of the tobacco plant. *Nature [London]* 128(3222): 187-188. 1931.—A virus disease was found at Amani, Tanganyika, of which the characteristic symptom is leafy outgrowths from the veins on the lower surface of the leaf. It has been transmitted by grafting and by transfer of an undetermined aleyrodid from diseased to healthy plants.

9224. VINSON, C. G., and A. W. PETRE. Mosaic disease of tobacco. II. Activity of the virus precipitated by lead acetate. *Contr. Boyce Thompson Inst.* 3(1): 131-146. 1931.—In juice from frozen diseased plants of *Nicotiana tabacum,* tobacco-mosaic virus was not completely inactivated at pH 1.8-1.9; activity falls off abruptly at pH 9.2-9.5. Norit or talc suspended in diseased juice greatly increases the infective power. The basic lead acetate precipitate obtained on clearing diseased juice, washed with successive portions of water, yields highly active suspensions. Decomposed with

H_2S, the pH of the suspension becomes too alkaline for the stability of the virus. The virus could not be recovered from the precipitate with oxalate, sulphate, or CO_2. From a neutral lead acetate precipitate from diseased juice, by elutriation with phosphate buffer at pH 6.5 or aqueous Na_2CO_3 in the presence of amyl alcohol, highly active preparations are obtained. Phosphate buffer at pH 4.5 elutes pigment but little virus. Directions are given for the preparation of a clear aqueous solution of the virus. Dilute Na_2CO_3 elutriates at pH 6.5 show 1-3% of the solid material of the original juice. Crystals obtained from aqueous sol. are inactive. From dilute acetone sol. at low temp. an active crystalline product is obtained.—*A. W. Petre.*

DISEASE RESISTANCE AND PARASITISM

9225. **BERKELEY, G. H., G. O. MADDEN, and R. S. WILLISON.** Verticillium wilts in Ontario. *Sci. Agric.* 11(11): 739-759. 10 fig. 1931.—The resting condition in the genus *Verticillium* is discussed and one type (torulose resting mycelium) is considered to belong to the *V. albo-atrum* group and the other (pseudo-sclerotium) to the *V. dahliae* group. Cross inoculation studies of the 2 type cultures (*V. albo-atrum* and *V. dahliae* on snapdragon, tomato, and potato) have shown *V. albo-atrum* to be a much stronger parasite in every case. *V. dahliae* is unable to produce wilt on snapdragon whereas *V. albo-atrum* is an active parasite. On tomato *V. albo-atrum* produces definite wilt whereas *V. dahliae* generally causes a slight stunting with yellowing of the lowest foliage but no wilt.—*G. H. Berkeley.*

9226. **HAMILTON, J. M.** Some relations of environment to apple scab and its control. *New York State Hort. Soc. Proc. Ann. Meet.* 76: 185-189. 1931.—The season of 1930 was not a particularly severe one for apple scab development. On May 16 about $\frac{1}{3}$-$\frac{1}{2}$ of the ascospores were mature. In general, the discharge of ascospores began on May 14 and ended about June 6. The main infection period occurred immediately after petal fall. There were 6 infection periods. The disease was found on the foliage on May 27 and was prevalent during the 1st week in June. Lesions did not appear on the fruit in any quantity until the 1st week in July. The experimental plots showed clearly that, where the trees had been well cared for and scab kept under commercial control, the milder treatments [dry-mix and Cal-Mo-Sul (calcium monosulphide)] were as effective as lime-sulphur. However, where there was a heavy source of inoculum, the weaker treatment was entirely inadequate. For practical purposes lime-sulphur and lime-sulphur+dry-mix (half and half) are approximately equally effective where scab is extremely severe. Dry-mix did not compare with sprays containing lime-sulphur. Best results were obtained with lime-sulphur continued through the calyx spray and the substitution of milder treatments for subsequent sprays. Lime-sulphur applied after infection periods of 43-47 hr. may effectively control scab under these conditions. —*J. M. Hamilton.*

9227. **HOLTON, C. S.** Hybridization and segregation in the oat smuts. *Phytopath.* 21(8): 835-842. 4 fig. 1931. —*Ustilago avenae* and *U. levis* are perfectly inter-fertile. Monosporidial lines of opposite sex fuse in culture and also produce smut on the host, regardless of whether crosses are made inter- or intraspecifically. Sporidial fusions do not occur within a monosporidial line of either species and neither do they occur in intra- or interspecific combinations of monosporidial lines of similar sex. When such combinations are used for inoculation, no smut is produced on the host. Intraspecific crosses produced the loose type of smut in the case of *U. avenae* and the covered type in the case of *U. levis* while the smut produced by the interspecific crosses was of the loose type. Intraspecific hybrid chlamydospore markings were characteristic of the species, but the interspecific hybrid chlamydospores were echinulate. Primary sporidia isolated from promycelia of germinating interspecific hybrid chlamydospores would not develop in culture with but rare exceptions. However, primary sporidia isolated from promycelia of germinating intraspecific hybrid chlamydospores developed normally. A cross between 2 monosporidial lines that originated from interspecific hybrid chlamydospores produced a buff type of smut which is apparently a new and previously undescribed type. The chlamydospores of this type were smooth and apparently colorless, in contrast to the dark brown chlamydospores of the common type of oat smut. Segregation for sex factors in *U. avenae* and *U. levis* was found to be on a 2:2 basis. There is strong evidence that a delayed segregation of factors for certain cultural characteristics occurs in *U. avenae* and *U. levis* since monosporidial lines originating from the same segment of the promycelium often exhibit striking differences in cultural characteristics.—*Author's summary.*

9228. **LEWIS, I. M.** The inhibition of Phytomonas malvaceara in culture media containing sugars. *Jour. Bacteriol.* 19(6): 423-433. 1930.—*Phytomonas malvaceara* fails to grow in culture media containing glucose, maltose, lactose, galactose, or levulose and various nitrogenous compounds when sterilized at 122° C. for 15 min. This is not due to lack of ability to assimilate the various sugars but to chemical changes caused by the high temp. of sterilization. Inhibition depends on the amount of peptone, sugar, and phosphate present; the reaction of the solution during the heating period; and the temp. and length of the period of sterilization. It is not due to changes in pH during sterilization. Inhibition occurs in culture media which, in the absence of the sugars, are suitable for growth. It is concluded that inhibition is due to conversion of the nitrogen compound into a form which is not suitable for assimilation by some species of bacteria.—*Author's summary and conclusions.*

9229. **LIMBOURN, E. J.** Flag smut of wheat. Variety resistance tests, 1926 to 1930. *Jour. Dept. Agric. Western Australia* 8(2): 214-217. 1931.

9230. **LINFORD, MAURICE B.** Transpirational history as a key to the nature of wilting in the Fusarium wilt of peas. *Phytopath.* 21(8): 791-796. 2 fig. 1931.—By following transpirational histories of diseased and healthy plants preliminary data have been obtained indicating that Fusarium wilt (*F. orthoceras* var. *pisi*) of peas may result not from a diminished water supply but from an excessive loss of water from the leaves, pointing to loss of normal powers of water retention by leaf protoplasts.—*From author's summary.*

9231. **LINFORD, MAURICE B.** Studies of pathogenesis and resistance in pea wilt caused by Fusarium orthoceras var. pisi. *Phytopath.* 21(8): 797-826. 9 fig. 1931. —*F. orthoceras* var. *pisi* can infect the pea plant and cause disease without the aid of other microorganisms or of gross mechanical injury. Peas grown in culture tubes on sterilized soil or on agar become infected readily upon inoculation. Wounding the root system slightly delays the appearance of symptoms in susceptible plants but does not lower the resistance of resistant peas. Dilution of highly infective soil with steam-sterilized soil leads to a greater retardation of the disease than a corresponding dilution with non-infested raw soil. A search for soil toxicity by the action of the wilt fungus gave only negative results. In the characteristic development of pea wilt under conditions favorable for the disease, there are definite changes in the affected plants which precede wilting and leaf necrosis. Pronounced dwarfing is accompanied by increased rigidity of the entire shoot, hypertrophy of the lower stem internodes, and rolling of leaf laminae. Before wilting begins, diseased pea stems lose water more slowly upon exposure to drying and have a higher content of dry matter with a proportionately increased ash content, an increased osmotic value of the cell sap, and an increased capacity for regeneration. These symptoms do not indicate general starvation or desiccation but suggest unbalanced nutrition and failure of translocation. Filtrates from cultures of the wilt fungus on Richards sol. produce a type of rapid necrosis in cut pea stems which appears comparable to the sudden wilting of young plants in

the early development of this disease. Varieties of peas differ in susceptibility to toxic culture filtrates, but experiments with 10 strains and varieties failed to reveal any correspondence between this and the resistance or susceptibility of the same varieties to Fusarium wilt. A shortage of water induced directly or indirectly by the fungus may sometimes be a factor in the wilting of large plants but probably not in the early collapse of young seedlings. In the main pathogenesis is attributed to toxic substances from the fungus within the host plant which lead first to a derangement of metabolic and growth processes and finally to death of the tissues. Actual wilting or slow necrosis is the culmination of a long series of changes.—*From author's summary.*

9232. **LINFORD, MAURICE B. Wound inoculation in relation to resistance in the Fusarium wilt of peas.** *Phytopath.* 21(8): 827-833. 2 fig. 1931.—By inoculation of young pea plants with *F. orthoceras* var. *pisi* through wounds in aerial parts, symptoms were obtained which partially simulated those typical of the pea wilt disease. A higher percentage of infection was obtained in this way in the resistant variety, Horal, than in the susceptible variety, Badger, and the course of the resulting disease was similar in both varieties. The results are taken to indicate that the expression of varietal resistance is largely localized within the root system.—*Author's summary.*

9233. **MITTER, J. H., and R. N. TANDON. A cultural study of two fungi found in an Indian hill apple.** *Jour. Indian Bot. Soc.* 8(3): 212-218. 1 pl., 3 fig. 1929.—Isolations from a decayed apple (probably from Kúlú) revealed 2 fungi, "A" and a species of *Sphaeropsis* (? *malorum*). Cultures of the fungi on various media confirmed their distinctness. Behavior in culture is described. Apples inoculated with "A" were only slightly affected, but those inoculated with *Sphaeropsis* sp. were completely rotted. This seems to be the first record from India of *Sphaeropsis* attacking apples.—*W. Dudgeon.*

9234. **RAEDER, J. M., and W. M. BEVER. Spore germination of Puccinia glumarum with notes on related species.** *Phytopath.* 21(8): 767-789. 3 fig. 1931.—A higher percentage germination of urediniospores of *P. glumarum* occurred in tap water than in distilled or rain water. The opt. relative humidity and temp. for retention of germinability of urediniospores of *P. glumarum* were 49% and 9-13°C., resp., at which spores remained viable 88 days. Urediniospores of *P. graminis phlei-pratensis* and *P. graminis tritici* remained germinable under the same conditions for 120 and 128 days, resp. Those of *P. triticina* were viable 124 days at 3-11° and a rel. humidity of 49%. Transferring spores which had been held at 49% rel. humidity at 29-30°, after all germination had ceased, to 9-10° for 48 hr. resulted in renewed germination in all 3 rusts. The spores of *P. glumarum* germinated 6 days longer; those of *P. graminis tritici*, 11 days; and those of *P. triticina*, 8 days. In like manner, the urediniospores held at 0° and 49% rel. humidity were transferred, after they had ceased germinating, to 23-26° for 48 hr.; thereupon spores of *P. glumarum* germinated 4 days longer, those of *P. graminis tritici* and *P. triticina* 6 days longer. Germination of teliospores of *P. glumarum* was first obtained in September, 1926, from newly collected material. At temp. prevalent in an ordinary ice refrigerator, teliospores retained their germinability longer than simultaneously collected spores held at 28-30°C. Teliospores incubated under these conditions apparently had lost their ability to germinate by the following spring but were revived by various stimuli. Many teliospores seemed to be impermeable to water. Lack of uniformity in germination is probably due to the age difference in the spores. Various stimuli produced inconsistent results in attempts to revive the capacity for germination. Immersing the spore-bearing material in a 1% sol. of citric acid for 15 min. induced spores to germinate after they had apparently lost this ability. Boric, hydrochloric, nitric, chromic, oxalic, sulphuric, lactic, and acetic acids, in 1% or weaker sol., seemed to stimulate germination. Induced germination of teliospores was not the result of any certain pH value of the acids. Fresh teliospores collected in 1927 did not possess the same germinating power as did those collected in 1926. Results obtained with ammonium thiocyanate, ethyl bromide, ethylene dichloride, an ethylene-oxygen mixture, and H_2O_2 were not conclusive of induced germination of teliospores. Alternate wetting and drying of teliospores at ordinary temp. did not induce germination, nor did freezing under air-dry conditions. Exposing teliospores to a combination of high humidity and freezing temp. resulted in a marked increase in germination. Abundant sporidia developed when teliospores were germinated in an exposed drop of water on a slide.—*From authors' summary.*

9235. **RIVERA, VINCENZO, e ENRICO CORNELI. Ricerche sullo sviluppo delle ruggini sul frumento in agro di Perugia. Memoria prima. [Development of wheat rust in the vicinity of Perugia.]** *Ann. Tecnica Agraria* 1 2(5): 545-588. 3 pl. 1929.—A rust map showing the areas where rust was epiphytotic and where it was moderate was prepared. A study of this map shows that clay soil induces susceptibility; that plants grown in soil of fine texture are much more disposed to rust than those grown in a coarse soil; and that a humid, shady locality is favorable for the development of an epiphytotic. Some of the different varieties of wheat included in the examination could be classified as to rust susceptibility; but with others, conflicting results, amounting to inversion of their usual resistance, were obtained. The problem of hibernation of the fungus is complicated due to the fact that the alternate host, *Berberis vulgaris*, is not attacked by *Puccinia* in this locality, and the teliospores appear not to form basidia. —*F. Gioelli (transl. by C. Chupp).*

DISEASE CONTROL (SEED TREATMENT, SOIL DISINFECTION, FUNGICIDES, AND SPRAYING)

9236. **SMALL, T. Tomato leaf mould.** *Exp. & Res. Sta. Nursery & Market Gar. Indust. Devel. Soc. Turner's Hill, Cheshung, Herts, Ann. Rept.* 16: 40-56. 1930 (1931). —Most fungicides gave better control of *Cladosporium fulvum* with Agral 1 than with saponin as a spreader. Effective control was had on pot plants by spraying with ammoniacal copper carbonate, colloidal sulphur A, and salicylanilide; the 1st was useful for spraying diseased crops. The disease was controlled by ethylene dibromide, quinone and thymol, in laboratory experiments, and by quinone in trials in a small glasshouse. Sulphur fumigation with Campbell's apparatus protected only the upper side of the leaves from infection and failed to kill the spores on the under side of diseased leaves. Inoculation tests showed that infection may occur on either side of the leaf. Large empty glasshouses may be practically freed from infection by fumigation with formaldehyde or SO_2. The min., opt., and max. temp. for germination of the spores of *C. fulvum* are: below 38°, 72-77°, and 89° F., resp. It is shown that the germ tubes can withstand considerable drying. The thermal death point of the spores is 115°F. Spores on diseased leaves were not killed by exposure to high temp. on several successive days.—*From author's summary.*

GENERAL AND MISCELLANEOUS PATHOLOGICAL LITERATURE

9237. **FRÖHLICH, JULIUS. Die wichtigsten Krankheiten der Bäume und Fehler des Holzes im südosteuropäischen Urwalde. [The principal tree diseases and defects of timber in virgin forests of southeastern Europe.]** *Forstwiss. Centralbl.* 53(8): 277-285. 5 fig. 1931.

9238. **HOPKINS, J. C. F. A list of plant diseases occurring in Southern Rhodesia. (June, 1930, to May, 1931.)** *Rhodesia Agric. Jour.* 28(7): 663-669. 1931.—List arranged by common names of hosts.

9239. **LEEFMANS, S. Ziekten en plagen der cultuurgewassen in Nederlandsch-Indië in 1928.** *Mededeel. Inst. Plantenziekten* 75: 1-96. 1929.—During 1928 the weather was on the whole wet. Cacao was attacked by

Helopeltis. On old *Hevea* trees in Sumatra and East Java white root fungus (*Rigidoporus microporus*) was most injurious; in West Java the red fungus (*Ganoderma pseudoferreum*) was more prevalent and the white root fungus attacked younger trees. In Sumatra a non-parasitic die-back of young trees occurred. Mites were harmful in all places. Nematodes attacked *Coffea* and, during wet weather, *Corticium salmonicolor* was prevalent. Injury by *Stephanoderes hampei* and *Xyleborus coffeae* was locally severe. For the 1st time the basidial fructification of *Fomes lamaoensis* was developed in culture. The mosaic and sereh diseases of sugar cane are being reduced by cultivating the variety P. O. J. 2878, which is however susceptible to 2 minor diseases, *Fusarium* and red stripe. Gum disease was serious. Of animal pests *Scirpophaga intacta* and *Oregma lanigera* were most important next to *Colobathristes saccharicida* and rats. Cinchona suffered from Psychidae and from Limacodidae as well as from *Helopeltis*. Slime disease destroyed 9% of the beds of tobacco and up to 36% of the older plants. Tobacco mosaic is prevalent and other virus diseases, as Rotterdam B and Kroepoek, were reported. In Java *Phytophthora nicotiana* was rather severe. The moth *Gnorimoschema heliopa* was the most injurious pest. Complaints were received of root fungi (*Ganoderma pseudoferreum* and *Rosellinia arcuata*) injuring tea. *Helopeltis* was generally found but was surprisingly absent from Central Java. For the 1st time *Rigidoporus microporus* was found on oil palm trees. In Java slime disease destroyed up to 50% of the potato harvest. In Sumatra virus diseases were bad. Next to these, potatoes suffered from *Epilachna*. *Arachis* was attacked by gapong disease (cause unknown). *Aproaerema* and *Cicadellinae* were important pests. A rat (*Mus rattus rufescens*) was reported to have destroyed many coconuts. Through the wet weather *Sclerospora javanica* on maize was very prevalent, the losses amounting to 50% of the crop. Cabbage suffered from *Pseudomonas campestris*. It was generally a good year for rice, with few diseases, though root rot occurred in Java. *Thrips tabaci* injured onions.—*H. L. G. de Bruyn.*

OSMOSIS, PERMEABILITY, PHYSICO-CHEMICAL PHENOMENA

9246. **BECK, WILLIAM A. The effect of drought on the osmotic value of plant tissues.** *Protoplasma* 8: 70-126. 1929.—The effect of drought on the osmotic value at incipient plasmolysis (O_s) was studied in 14 different experiments, on the various tissues of the leaf of *Hedera helix*. In the 2nd part of the work the data collected are so arranged that the effect of drought and the accompanying factors can readily be detected for the different tissues. The initial value of a tissue was characteristic for that tissue. The O_s rarely remained constant for a given tissue throughout the course of an experiment. The variation of O_s under the influence of a given combination of factors was characteristic for the epidermal tissues, the guard cells, and the assimilating tissues.—The O_s variations of the epidermis show the least range, speed, and regularity in its response to the

imposed influences in general and to drought in particular. In certain cases the guard cells responded best, but in most cases the assimilating tissues manifested greatest regularity, speed, and degree of response, particularly to drought. The epidermal tissues were very irregular in their response, which seems to indicate that the influence of the accompanying factors easily predominates over the influence of the drought. The reluctance in the epidermal tissues to respond is in harmony with its function as a protective tissue. To a slight extent the epidermis might act as a reservoir of water for the assimilating tissues; the results do not refute such a possible function. Drought causes a marked and rapid increment of the O_2 of the palisade cells. Light is the most effective accompanying factor. Full water supply, 100% relative humidity in the atmosphere, and darkness cause a decrement. Drought causes a marked and rapid increment of the O_2 of the conducting parenchyma. Light is less effective in this tissue than in the palisade cells. Full water supply, 100% relative humidity in the atmosphere, and darkness cause a decrement.—*From author's summary.*

9247. BOAS, FRIEDRICH. Das phyletische Anionenphänomen. Ein Beitrag zur Hylergographie. 94p. 12 fig. Gustav Fischer: Jena, 1927. Pr. 6 M.—"Hylergography" is defined as the study of the effects of substances ("hyles") on the functional capacity of cells with a view to furthering knowledge of cell structure, and is the biological branch of dynamic physical chemistry. The selective effect of common anions on microörganisms (the "anion phenomenon") is one phase of this study. It is well shown in the case of fungi and bacteria, one or the other of which may be entirely suppressed in mixed cultures by proper choice of the anions present; only fungi grow in the presence of 0.2 M NaSCN or KSCN, while in 0.2-1.0 M Na_2SO_4 extremely vigorous growth of bacteria takes place. Iodides (0.3-0.4 M NaI) act like sulfocyanides. Anions may be arranged as to their effects on fungus and bacterial growth in graded series of ascending effectiveness: bacteriotropic → SCN, I, Br, NO_3, Cl, SO_4, P_2O_5 ← mycotropic. Growth of bacteria in yeast-water sugar media is inhibited by Na salts in about the following molar concentrations: 0.2 NaSCN, 0.4 NaI, 1.0 NaBr, 1.6 $NaNO_3$, and 1.6 NaCl; Na_2SO_4 in such concentrations does not inhibit. This is the order of decreasing penetrability into cells and of decreasing toxicity and ionic hydration. The effect of sulfocyanide is increased by caffeine, salicylate, $CaCl_2$, and $MgCl_2$. Guanidine sulfocyanide is especially active. Iodide and sulfocyanide are synergic. The anion phenomenon is regarded as due to inhibition of growth by colloidal swelling of cells caused by anions, and therefore dependent in part upon differences in permeability of fungus and bacterial cells to different anions. Gram positive and Gram negative bacteria are discussed, and also the effects of bile salts which resemble those of sulfocyanide.—*F. Boas (transl. by S. C. Brooks).*

9248. FERNALD, EVELYN I. Freezing point depressions of asparagus shoots determined by a thermoelectric method. *Contr. Boyce Thompson Inst.* 3(4): 483-498. 3 fig. 1931.—Copper-constantan thermo-couples were inserted 1 cm. deep into portions cut from asparagus shoots. The portions were usually 2 cm. long and 1 cm. in diameter. The range of values had a tendency to be high at the tip, decreasing to a point near the soil line, where there was a slight rise, which was followed first by a decrease and then by an increase near the crown. The greatest values for the freezing point depressions were found in the majority of cases in regions 1 cm. and 3 cm. from the tip of shoots still below the surface of the soil. A similar distribution of values was observed in the majority of shoots whose tips had emerged from the soil 1.5 to 3.7 cm. The distribution of maximum and minimum values was less regular in shoots whose tips were more than 5 cm. above the soil.—*E. I. Fernald.*

9249. FREY-WYSSLING, ALB. Theorie des Blutens. *Ber. Deutsch. Bot. Ges.* 47(7): 434-450. 4 fig. 1929.—Bleeding is explained in correlation with osmotic conditions as set forth by the method of Ursprung and Blum. When the vessels are cut the turgor falls to zero, but their absorbing power increases, since in the equation: Absorption power of the cell = absorption power of the cell contents − turgor, the right side increases very rapidly. By reason of the increased absorbing power of the cells they can withdraw water from the adjacent parenchyma cells, which flows out as "bleeding sap." The dead vessels possess no wall pressure, so that their turgor endures only by reason of the external pressure brought to bear on them by neighboring cells. The bleeding pressure can, therefore, be defined as the external pressure acting upon the vessels. But in the phenomena of bleeding this pressure seldom acts alone; it is generally eclipsed by root pressure, which is defined as an excess filtration pressure, by which certain cells of the root parenchyma force water into the vessels.—*A. Frey-Wyssling (transl. by P. D. Strausbaugh).*

9250. MOORE, J. C., R. G. REEVES, and R. M. HIXON. Electrodialysis as a means of studying biochemical differences in abnormal apple tissue. *Plant Physiol.* 2: 313-324. 6 fig. 1927.—The dialyzable electrolytes were separated from the peelings of Jonathan apples using the Mattson electrodialysis cell. The course of the separation was followed by periodic titration of the accumulated acids and bases in the anode and cathode compartments. The anthocyanin pigment migrates as a positive ion necessitating the electrolytic titration of the basic constituents. The results vary according to the conditions of the experiment but they consistently indicate a higher ratio of basic radicals, as compared with the acidic radicals, in the peel of those apples affected by Jonathan spot.—*R. M. Hixon.*

WATER RELATIONS, SAP MOVEMENT

9251. APPLEMAN, C. O., W. D. KIMBROUGH, and C. L. SMITH. Physiological shrinkage of potatoes in storage. *Maryland Agric. Exp. Sta. Bull.* 303. p. 159-175. 1928.—The decrease in wt. of potato tubers during storage is caused largely by loss of water in transpiration, the loss of solids calculated from the CO_2 respired being much smaller. Measurable fluctuations in rate of shrinkage are attributed to changes in rate of transpiration caused by changes in internal physiology. Fluctuations were determined by comparing the loss in wt. of tubers with the evaporation from an atmometer. The rate of transpiration was high immediately after harvest, reaching a low level during the winter, and increasing again when the tubers started to sprout. Differences in 16 varieties were manifested only during early and late storage. Potatoes dug before they were mature transpired about twice as rapidly for a few weeks after digging as those allowed to mature in the field. The removal, at weekly intervals, of the sprouts from tubers sprouting in storage reduced the loss of water below that of those allowed to develop sprouts normally. The actual loss in wt. during storage was higher at low temp. than at high.—*J. Bushnell.*

9252. HUBER, BRUNO. Untersuchungen über die Gesetze der Porenverdunstung. *Zeitschr. Bot. (Festschr. Oltmanns)* 23: 839-891. 14 fig. 1930.—Because of the retarding influence of stomatal movement on evaporation, model evaporation systems were constructed with perforated metallic foils to aid in stomatal transpiration studies. Pore density, expressed as "relative pore area" (ratio of total pore surface area to total system surface area), and pore size were varied in these systems. Constant pore size with an increasing pore area, and constant pore area with the area made up of more but smaller pores, both increased relative evaporation (all evaporation values were converted to a free evaporation surface of equal size). The increase in evaporation from increased pore area is not linear but hyperbolic, due to the increasing counteraction on evaporation by the pores (stomates). The quantitative counteraction can be determined mathematically. Stefan's diameter law, which states that evaporation increases proportionally to pore diam. (not pore area), is valid for evaporation from

pores of different diam. except the smaller ones, for which it gives relatively high results. It is uncertain for small pores and for pores far apart because of their considerable countermovements to evaporation, and can only be demonstrated by mathematical extrapolation on the evaporation from undisturbed pores. The actual output of such pore systems is considerable; pores 50μ in diam. with 5% pore area evaporate 92% as much as a free surface. In wind, evaporation is relatively less, i.e., it increases less through the pore system than from a free surface. The extent of this reduction depends primarily on the pore area and secondarily on pore diam. The output of the pore system is relatively less in dry than in moist air.—*B. Huber* (*transl. by N. A. Pettinger*).

9253. **MASKELL, E. J., and T. G. MASON. Studies on the transport of nitrogenous substances in the cotton plant. IV. The interpretation of the effects of ringing, with special reference to the lability of the nitrogen compounds of the bark.** *Ann. Botany* 44(174): 233-267. 2 fig. 1930.—This paper deals with evidence from short period ringing experiments as to the form in which the longitudinal transport of organic N takes place. Response to ringing consisted of accumulation of substances in bark above ring (or decrease below); in some cases the substance involved was mainly protein N, and in others mainly crystalloid N. Interpretation is complicated by the fact that rate of conversion of crystalloid to protein N, and vice versa, in the bark may be very rapid compared with rate of longitudinal transport of N. Three types of conversion were observed: (1) A conversion of protein to crystalloid N, highly correlated with the decrease in sugar concentration brought about by defoliation or by isolation from the foliage region, paralleled by behaviors of the N in the wood; (2) Conversion of crystalloid to protein N during desiccation, the actual concentration of crystalloid N not diminishing; (3) A rapid conversion, during the day, of crystalloid to protein N, usually occurring when the initial value of the crystalloid: protein N ratio is much above the average. This type of rapid change involves principally asparagine and amino acid N, the residual N fraction being less affected. It was observed only in the bark and not in wood or leaf. The lability phenomena suggest that all N fractions, including labile protein, may contribute to longitudinal adrenal within the sieve tube system; but that movement into and out of the surrounding tissues may be restricted to some crystalloid fraction (possibly residual N) that does not take part in the rapid fluctuations of crystalloid: protein ratio in the bark. The type of ringing response observed, i.e., whether crystalloid or protein N, appears to depend on time interval since ringing (effect of increased sugar concentration on protein: crystalloid ratio), and, when rapid change in the protein: crystalloid ratio is in progress, on the mean level of that ratio during the experiment and the direction of change. Thus character of response is liable to be determined by chemical changes subsequent to transport. In addition, the N response is not, like the sugar response, mainly confined to the region of the sieve tubes but there is considerable spread to surrounding bark tissue and to the wood.—*E. J. Maskell.*

9254. **MASKELL, E. J., and T. G. MASON. Studies on the transport of nitrogenous substances in the cotton plant. V. Movement to the boll.** *Ann. Botany* 44(175): 657-688. 7 fig. 1930.—Two phases of the subject were studied in 1 experiment on each: (1) Effect of removing bolls on N and carbohydrate compounds in leaf, bark, and wood in upper and lower regions of the plant; and (2) uptake of N and carbohydrates by the young boll and the effect of fertilization of the boll. Removal of bolls was followed by increase of N and carbohydrates in leaf, bark, and wood in both regions. The dry wt., less 5.7 times the wt. of N, considered as non-nitrogenous compounds, mainly carbohydrates, increased significantly only in the upper region, whereas the increase in total N was everywhere significant, and the N response was very much greater than the carbohydrate response, except in the leaves of the upper region, thus confirming Murneek's findings that the developing fruits cause a bigger drain on the N than on the carbohydrate supplies of the plant. Polysaccharides accounted for a large part of the carbohydrate response. Protein N increased particularly in the leaves and upper region of the bark, whereas crystalloid N increased in all regions and in general more than protein N. Nitrates remained unchanged in the leaves but decreased in bark and wood of upper region. In general, removal of bolls gave results somewhat similar to those obtained by ringing the stem near its base. The pH value of the sap showed no significant changes on removal of bolls. In the 2nd experiment a marked difference in the uptake of N and carbohydrates by the fertilized and unfertilized bolls became apparent in both ovules and carpels on the 4th day after anthesis, as well as a definite divergence in the march of sap concentrations of certain compounds. No distinction could be drawn, however, between the effect on carbohydrate uptake and the effect on N uptake. Increased rate of utilization and increased rate of entry are 2 types of change that may account for the increased uptake by the fertilized bolls.—*M. C. Merrill.*

9256. **NEWTON, R., and W. M. MARTIN. Physicochemical studies on the nature of drought resistance in crop plants.** *Canadian Jour. Res.* 3(4): 336-383; (5): 385-427. 4 pl. 1930.—Hydrophilic colloids bind water and increase the concentration of aqueous solutions, as shown by freezing-point determinations. Dextrose is less effective than sucrose in demonstrating this phenomenon. Concentration, quality, and state of dispersion or coagulation of colloids affect the degree of water binding. The hydrolysis of sucrose added to plant juice in the bound-water determination was shown not to introduce serious errors. Storage of leaf tissue or press juice for a few hrs. even at 0° C. leads to changes in colloidal properties, but errors from this source are avoided by prompt handling. Cylindrical dialyser sacs of 100 cc. capacity required about 48 hrs. for dialysis of plant juice at 3° C., with the water changed every hr. A gradual partial coagulation of colloids took place during dialysis, as shown by a decrease in refractive index, by an increase in gold number, and by sedimentation when centrifugalized. Hydration and dispersion were not always related, though both were affected by pH value and salts. Acid and alkaline salts stimulated hydration less because of the opposing "salt effect." In the presence of the natural crystalloids, hydration was usually greater than in dialysed juice. The osmotic pressure of the tissue fluids of crop plants varied with physiological scarcity of water, but was not a reliable index of drought resistance. Bound-water content was more dependable; the cultivated wheats and several grasses have been on this basis satisfactorily arranged in the order of their drought resistance. The contrasting behavior of 2 poplar sp., with reference to leaf fall and frost resistance, has also been explained. The separation of the colloids by dialysis and the determination of their gold number have been used as aids in interpreting the bound-water values. The method of measuring imbibition pressure by direct pressure on masses of leaves proved unsuitable. The rates of water loss by evaporation from cactus segments and detached leaves of 2 grasses, under controlled humidity conditions, proved the remarkable ability of the cactus to retain moisture, but in the grasses showed no relation to drought resistance.—*R. Newton.*

9257. **[RICHTER, A. A., E. I. DVORETSKAĬA, and A. I. GRECHUSHNIKOV.]** РИХТЕР, А. А., Е. И. ДВОРЕЦКАЯ, А. И. ГРЕЧУШНИКОВ. О факторах устойчивости культурных растений. I. Транспирация

и дезассимиляция инфицированных грибком организмов. [Perseverance of cultivated plants. I. Transpiration and katabolism of organisms infected with fungous diseases.] Журнал Опытной Агрономии Юго-Востока. (*Jour. Exp. Landw. Südosten Eur. Russlands*) 7(2): 99-114. [German summary p. 150.] 1929.—Fungous infection leads to a noteworthy decrease in life processes of the infected plants by strongly influencing transpiration and respiration. Under similar external conditions, water excretion is more rapid in infected than in healthy plants. Results obtained in the measurement of transpiration (potometer method) correspond well with data obtained in studying the changes in the stomata. In infected plants the stomata showed a noticeable tendency toward excessive opening. A potometer study on diseased leaves showed a decreased internal ventilation. The katabolic processes in diseased organs are usually strongly accelerated and lead to an excessive excretion of CO_2. The decreased respiration observed in various badly diseased plants is apparently due to a prolonged deficiency of food stuffs. The "biological resistance" of plants infected by fungi is greatly diminished.—*Authors' summary (transl.)*.

9258. SCARTH, GEO. W. Sinkage studies IV. The mechanism of the absorption of water by wood blocks. *Canadian Jour. Res.* 3(2): 107-114. 1930.—Uniform blocks of white pine wood were allowed to absorb water under various conditions of external and internal pressure, and in the presence and absence of air. The results (shown graphically) give some idea of the quantitative relation existing between penetration of water into wood and the various forces operating. It is concluded that the rate of penetration of water into an immersed block of coniferous heartwood is fixed by the rate at which the air in the block can dissolve and diffuse out. Applied to log sinkage, these findings show that under most conditions the limiting factor is the rate of escape of air from the log.—*Author's abstract.*

9259. SEYBOLD, A. Die pflanzliche Transpiration. 2. *Ergebnisse Biol.* 6: 559-712. 40 fig. 1930.—This part treats of the physiological components of transpiration: the dependence of the transpiration system on water content, temp., light, wind, and wilting; the influence of chemical agents; correlation processes; transpiration and guttation. In addition, the most important ecological articles on the measurements of transpiration are critically compiled with a comprehensive citation to literature.—*A. Seybold (transl. by A. D. Moinat).*

9260. [STUL'NIKOV, M.] СТУЛЬНИКОВ, М. Влияние ассимилятов на интенсивность транспирации. [The influence of the assimilate on the intensity of transpiration.] [German summary.] Известия Саратовского Общества Естествоиспытателей. (*Ber. Saratower Naturforscherges.*) 2(2): 64-80. 1928.—Experiments were undertaken to determine the relationship between the intensity of transpiration and the accumulation of plastic constituents in leaves. The method employed was the comparison of evaporation of excised leaves and branches. Some were kept up to the time of the experiment under conditions favoring the accumulation of assimilate (in light in favorable surroundings and in sugar solutions); similar leaves were kept under conditions favoring a loss of assimilate (in darkness and in media deprived of CO_2). Leaves of various plants deprived of starch kept in darkness and then placed in diffused light lost less water by evaporation during the first hrs. than those which were kept in light prior to the test. In succeeding hrs. the intensity of transpiration of the 2 sets tended to become equal. Leaves which were kept for 2 days in light and in a medium deprived of CO_2 increased the intensity of their transpiration 2-3 times as much as leaves which have been kept in darkness. Leaves which for 2 days before the experiment had been kept with their petioles or with their surfaces in contact with 0.5% sucrose solution, varied the intensity of their transpiration to a certain degree. In such experiments, leaves of such plants as *Syringa vulgaris, Pelargonium,* and *Panicum miliaceum* transpired on the average 1½ times as much as similar leaves which had been kept in water prior to the experiment. The leaves of such other plants as *Amaranthus retroflexus* and *Solanum nigrum* lost considerably less by evaporation. Ringed branches (*Syringa vulgaris*), excised 9 days after ringing, lost by evaporation 2-3 times less than similar branches which had not been ringed. In experiments with ringed branches kept in darkness, the same phenomenon was observed; normal branches kept in light before the experiment evaporated more than ringed branches. It is concluded that there is no close relationship between the intensity of transpiration and the presence of plastic constituents in the leaves.—*Author's summary (transl.).*

9261. VALMARI, J., ja VILJO KANERVO. Kasvien vedenkäyttö ja säätekijät. [Water consumption of plants in relation to the weather.] [German abstract.] *Valtion Maatalouskoetoiminnan Julkaisuja* [*Helsinki*] 26: 1-90. 1930.—This is a general account of some significant water relations together with some original observations. The transpiration coefficients of different cultivated plants with a complete fertilizer are given. The comparison is difficult because the data are from different yrs., and the fertilizer is not constant. However, the transpiration coefficient of peas is distinctly smaller than that of barley, although the peas were given less N fertilizer. The relative consumption of water by oats, however, is greater than that of barley under the same conditions.—*From author's conclusions (transl. by H. H. Clum).*

MINERAL NUTRIENTS, SALT RELATIONS

9262. AITKEN, H. A. A. Sulphur in organic and inorganic combination in pasture grasses. *Biochem. Jour.* 24(2): 250-256. 1930.—A method was devised for the estimation of sulphate-S in grass or green leaves.—*E. B. Carmichael.*

9263. BERTRAND, GABRIEL, et M. ROSENBLATT. Le potassium et le sodium dans les algues marines. *Compt. Rend. Acad. Sci.* [*Paris*] 187(5): 266-270. 1928.—Sp. of *Fucus, Pelvetia, Ascophyllum, Cystoseira, Himanthalia, Laminaria,* and *Padina* were investigated, and it was found that K is present in *Fucus,* that in marine algae there is not ordinarily a strong predominance of Na over K content, and that some algae lose their salts more readily than others when subjected to a series of washings in fresh water.—*D. Doubt.*

9264. DANGEARD, PIERRE. Action favorisante de l'iodure de potassium sur l'iodovolatilisation. *Compt. Rend. Acad. Sci. Paris.* 187(24): 1156-1158. 1928.—KI in 0.1% sea water solution causes an intense I emission in *Laminaria* and the Fucaceae. The use of iodide made it possible to observe iodovolatilization in several Rhodophyceae (*Gracilaria, Calliblepharis*).—*P. Dangeard (transl.).*

9265. HAAS, A. R. C. Boron as an essential element for healthy growth of citrus. *Bot. Gaz.* 89(4): 410-413. 1930.—Grown in water cultures containing Na, K, Ca, Mg, Fe, NO_3, Cl, SO_4, and PO_4 in the following proportions (in parts per million): 7, 185, 159, 54, 1, 718, 10, 216, and 105, growth was poor, and there was noted a curling of the leaf along the midrib, accompanied by yellowing, a corky appearance of the veins, progressive (basipetal) fall of affected leaves, multiple bud formation, splitting of the bark of internodes, and gum flux through the splits in the bark. Addition of traces (0.2 p.p.m) of Al, I, Ti, Br, Sr, Li, Mn, NH_3, and B, to the culture medium, avoided and corrected these symptoms and good growth was obtained. An attempt was made to determine which of the above 9 elements or radicals was effective in overcoming the deficiency by setting up a series of experiments in which all but 1 were present in each culture. In these experiments the omission of B was found responsible.

9266. KŌKETSU, RIICHIRO, und HIROSI KOSAKA. Bestimmung des "spezifischen Pulvergewichtes" verschiedener gehüllten Reiskörner mittels der "Pulvermethode" und ihre Bedeutung. [In Japanese.] *Proc. Crop*

Sci. Soc. Japan 2: 7-12. 1928.—Using Koketsu's powder method, it was found that specific powder wt. of rice grains gradually increases as maturity progresses, is smaller for grains from plants grown on fertile soils as compared with infertile soils, and is also smaller for grains from plants grown on saline swamp soils as compared with ordinary swamp soils.—*Author* (*courtesy Japanese Jour. Bot., transl. by N. A. Pettinger*).

9267. **NIETHAMMER, ANNELIESE.** Über die verschiedenen Möglichkeiten der Beeinflussung des Wachstums von Aspergillus niger durch abgestufte Mengen von Zink- und Mangansalzen. *Beitr. Biol. Pflanzen* 17 (1): 51-71. 1929.—This paper is largely polemical, but data are also presented on the variation in growth of *A. niger* with variation in concentration of the nutrients (especially Zn, Mn, and sugar) and length of growth-period.—*R. A. Steinberg.*

PHOTOSYNTHESIS, CHLOROPHYLL

9268. **BERGAMASCHI, MARIA.** Sull'assorbimento del biossido di carbonio per opera delle radici e sulla sua utilizzazione nella fotosintesi clorofilliana. Nota preliminare. [Absorption of CO_2 by roots and its use in photosynthesis.] *Atti Ist. Bot. "Giovanni Briosi" e Lab. Crittogam. Italiano Univ. Pavia* 1: 89-94. 1929 (1930).

9269. **KRASNOSSELSKY-MAXIMOV, T. A.** Zur Methodik der Bestimmung von Assimilation und Bewegungen der Spaltöffnungen in natürlichen Verhältnissen. *Ber. Deutsch. Bot. Ges.* 47 (5): 313-320. 2 fig. 1929.—A 99% efficient absorption tube suitable for either field or laboratory use is described. It consists of a glass tube *A*, 16mm. wide and 55cm. long, which widens at the upper end into tube *B*, 38mm. in diam. and 20cm. long. To the lower end is fused a thick-walled tube *C*, 7mm in diam. and with a bore of 2mm. *C* is bent back along *A* to a height of 30cm. and the free end bent at a right angle. A perforated German-silver disc is cemented into *A* at the point where it tapers into *C*. There are 25 0.15-0.20mm. holes in the plate which were made with the aid of an ocular micrometer. Smaller holes become clogged and larger ones decrease the efficiency of the apparatus. *B* is closed with a 1-holed rubber stopper into which is inserted a glass plug and *C* is closed with a short piece of rubber tubing and a clamp. The absorbing agent used was $Ba(OH)_2$ and the titration, carried on within the tube, was made with oxalic acid using phenolphthalein as an indicator, after the manner of Boysen-Jensen. The necessary solutions are admitted through the hole in the rubber stopper of *B* by means of a fine pipette. When the solutions within the tube are being mixed during a titration, the rubber tubing on *C* should be gently pinched while the apparatus is being held upside down so as to dislodge any unmixed liquid below the plate. A few suggestions in regard to the leaf chamber and aspirator are also made. The use of the Kley model Opak-Illuminator supplied by the firms of Leitz and Reichert is highly recommended for studying the stomata under natural conditions.—*W. H. Michaels.*

9270. **POLLACCI, GINO, and MARIA BERGAMASCHI.** **Dimostrazione con la dimetilidroresorcina della formazione di aldeide formica in piante vive durante la fotosintesi clorofilliana. Nota preliminare. [Demonstration, by means of dimethylhydroresorcin, of the formation of formaldehyde in the living plant during photosynthesis.]** *Atti Ist. Bot. "Giovanni Briosi" e Lab. Crittogam. Italiano Univ. Pavia* 1: 157-160. 1929 (1930).

9271. **VORLÄNDER, D.** **Der angebliche Nachweis von Formaldehyd bei der Assimilation der Kohlensäure.** *Zeitschr. Wiss. Biol. Abt. E. Planta* 6 (4): 684-686. 1928.—The reagent dimedon was used some 3 yrs. ago by Klein and Werner to show that formaldehyde was the intermediate product in the formation of carbohydrates from CO_2 and H_2O during photosynthesis. This reagent belongs to the same group (dimethylhydroresorcins) as methon, which Vorländer used many yrs. ago. This reagent itself gives formaldehyde through the oxidation of the group CO. CH_2CO, so that the controversy concerning formaldehyde as an intermediate product is still unsettled.—*R. P. Hibbard.*

BIOCHEMISTRY, METABOLISM (GENERAL)

9272. **BALDWIN, M. E.** **Separation and properties of the two main components of potato starch.** *Jour. Amer. Chem. Soc.* 52 (7): 2907-2919. 1930.—This method for fractionating potato starch effects the separation of the outer envelope of the grains (α-amylose) from the inner more soluble portion (β-amylose). It is based on difference in solubility and consists of subjecting gelatinized grains to freezing and extraction carried out under experimentally established conditions. A sharp separation is indicated by the contrasting and antithetical properties of the amyloses: β-amylose represents $16 \pm 1\%$ of the starch; α-, $84 \pm 1\%$; β- is "P-free," α- contains 0.076% P; β- gives with I a blue color, free from violet; α-, a red-violet, free from blue; β- is precipitated by alcohol and by I, α- is not precipitated; β- retrogrades, α- does not.—*M. E. Baldwin.*

9273. **CLARK, GEORGE L.** **Cellulose as it is completely revealed by x-rays. Special application to the growth and classification of cotton, the structure of wood and the manufacture of rayon.** *Indust. and Engineer. Chem.* 22 (5): 474-487. 28 fig. 1930.—The data include the size of the unit crystal cell, the presence of long primary valence chains in bundles, the size of the colloidal micelles, and their orientation with respect to the fiber axis. Utilizing this definite structure, rational explanation is given for many of the physical and chemical properties of cellulose fibers. Great improvements in x-ray technic as used in the study of cellulose are outlined. The growth of cotton fibers from the root hairs to the mature fiber is presented to show the various stages in the botanical process. X-ray patterns are also utilized as a possible method of classification of grades of cotton. Diffraction patterns are used to obtain information upon 7 classes of facts as regards wood. These include comparison of wood structure; comparison of tangential, radial, and cross sections; wood swelling; the variation in structure upon the leaning side of trunks and the under side of boughs; extension to studies of wood pulp; and fundamental measurements on specimens representing various grades of disintegration down to the "fusiform bodies" discovered by Ritter.—*G. L. Clark.*

9274. **DADSWELL, H. E., and L. F. HAWLEY.** **Chemical composition of wood in relation to physical characteristics.** *Industr. and Engineer. Chem.* 21 (10): 973-975. 1929.—This research has shown that a certain type of brash oak has slightly higher lignin content and slightly lower cellulose content than tough wood of the same sp., and that compression wood has considerably higher lignin content and lower cellulose content than the normal wood of the same sp. taken from relatively close positions in the same tree. The dense summerwood bands isolated from redwood compression wood have higher lignin content than the springwood bands from the same annual growth rings. These differences are contrary to those generally found in the analyses of the springwood and summerwood of normal wood of any sp. No general conclusions can be drawn on the effect of lignin on strength without knowing the portion of the wood structure in which the variations in lignin content occur.—*Authors' summary.*

9275. **DISCHENDORFER, OTTO, und OSKAR POLAK.** **Untersuchungen auf dem Gebiete der Phytochemie. V.** *Akad. Wiss. Wien. Math.-Naturwiss. Kl. Abt. 2B Sitzungsber.* 137 (10): 995-1010. 1928.—Betulin, a substance found in the European white birch, does not readily form derivatives, reverting into waxy products, but by gentle oxidation, it may be changed to allo-betulin, an isomeric form, which yields easily purified crystalline compounds. A study of the preparation and constants of a number of such derivatives throws much light on the chemistry and constitution of betulin and allobetulin.—*O. F. Black.*

Analyse der Fette und Wachse. Band 2. Systematik, Analysenergebnisse, Bibliographie der natürlichen Fette und Wachse. [Analyses of fats and waxes.] xv+806p. Julius Springer: Berlin, 1929.

9277. **HARLOW, WILLIAM M., and LOUIS E. WISE. The chemistry of wood. I. Analysis of wood rays in two hardwoods.** *Industr. & Engineer. Chem.* 20(7): 720-722. 5 fig. 1928.—The larger wood rays were isolated from fine shavings of white oak, *Quercus alba*, and of Australian flame she-oak, *Casuarina inophloia*. Chemical analysis shows the rays to be higher in lignin and lower in cellulose than is the total wood.

9278. **HASSELBRING, HEINRICH. Carbohydrate transformations in carrots during storage.** *Plant Physiol.* 2: 225-243. 1927.—Carrots stored at 39-40° C. lost about 26% of their wt., and stored at 32-35° C. about 7%. This loss is mainly water, as the loss in solids is only about 1% for the 22 weeks of storage. The 2 main transformations in the carbohydrates are of sucrose to reducing sugars, and of polysaccharides to simple sugars. These processes go on more rapidly at the higher than at the lower storage temp. At the higher temp. 43% of the sucrose and 33% of the polysaccharides disappear during the 1st 10 weeks of storage, as compared to 28 and 20%, respectively, at the lower temp. Under constant conditions the transformations reach a sort of equilibrium within 10 weeks, after which the changes are much slower. Since the flavor of carrots depends on the sucrose content largely, canning and cooking quality is highest just after they are dug.—*C. A. Shull.*

9279. **HÖNL, VIKTOR. Über die Energiespeicherung der Pflanzen mit Berücksichtigung ihres Kohlenstoff- und Stickstoffgehaltes. II.** *Biochem. Zeitschr.* 225(1/3): 94-114. 7 fig. 1930.—With all of the plants investigated, calories, C, and also N content per gm. of ash-free dry substance decreased gradually during development. These decreases were definitely greater with nonlegumes (buckwheat, corn, turnip) than with legumes (lupines, peas). Accordingly the C/N ratio in the latter remained almost constant in the course of their development while with nonlegumes in general it increased. The mineral portion of the plant material changed only a little with legumes but with the others it began to decrease in the early stages of growth. These fluctuations in ash content have great influence on the course of the curves for calories and C for the ash-containing material. Nourishment has less influence than age on energy accumulation and on C and N content. With a lessening N and P_2O_5 supply the C content and the calories of the final harvest (oats) decreased. The C/N ratio first increased then decreased with increasing N additions, but with increasing P_2O_5 additions it fell steadily.—*Author's summary* (*transl. by L. T. Leonard*).

Oslo, I. Mat.-Nat. Kl.* 1929(4): 1-14. Map. 1929.—King Öistein of Norway built a wooden pier at Agdenes, just at the mouth of Trondhjemsfjord, about 800 yrs. ago. In spite of the long contact with sea water in a very severe climate, the wood has scarcely been attacked by *Teredo*, and it shows only a very weak reaction with the ordinary reagents for lignin (HCl with phloroglucine or aniline). It is, therefore, concluded that the lignin has disappeared and a purer cellulose is left.—*J. Sebelien.*

9287. **SHERRARD, E. C., and E. F. KURTH. Occurrence of pinite in redwood.** *Indust. & Eng. Chem.* 20(7): 722-723. 1928.—Pinite, $C_6H_5OCH_3(OH)_5$, occurs in the heartwood of *Sequoia sempervirens*. Methods of extraction are given.

9288. **STURA, MARIA BARGONI. La maturazione dei frutti di alcune diospyracee (D. kaki, lotus e virginica).** [Ripening of persimmons.] *Natura* [*Milano*] 17 (2): 64-75. 1926.—Maturation of persimmons takes place in 2 stages. In the 1st there is an accumulation of reserve materials, together with a small amount of tannin, which in the free state retards the development of the 2nd stage. On the disappearance of the free tannin there is a transformation of pectose to pectin, whose swelling occludes the intercellular spaces and thereby leads to anaerobic respiration, fatty degeneration, formation of traces of alcohol, and destruction of middle lamellae, all of which constitute the 2nd phase. The free tannin is partly disposed of by oxidation, but this is incomplete in Italy because of the low temp. during ripening. Instead, the cold causes the cells to precipitate out the tannins on the plasma proteins, thus removing them from inhibiting pectoclasis.—*Author's conclusions* (*transl. by H. S. Wolfe*).

9289. **[SUKHORUKOV, K. T.]** СУХОРУКОВ, К. Т. **Содержание дубильных начал в некоторых растениях Нижне-Волжского края. [Tannin content in some plants of the Lower Volga region.]** [German summary.] Журнал Опытной Агрономии Юго-Востока. (*Jour. Exp. Landw. Südosten Eur. Russlands*) 7(2): 89-97. 1929.—Roots of *Statice latifolia* contain 19.29% tannin; of *S. gmelini* 16.07%. Excepting *S. suffruticosa*, leaves and stems of all the sp. of *Statice* contain lower %. Roots of *Statice* collected at the close of the vegetative season showed a greatly diminished tannin content. Young branches of 2 spp. of *Tamarix* gave up to 12%

tannin. Fruits of *Rheum rhaponticum, R. accumum,* and *R. undulatum* contained 6.5-10.5%. Extraction of tannin from 2 spp. of *Statice,* according to Meno's method, gave very low figures.—*From author's summary (transl.).*

9290. **THOMAS, R. C. Composition of fungus hyphae. II. Sclerotinia.** *Amer. Jour. Bot.* 17(8): 779-788. 1930.—The hyphae of *Sclerotinia duriaeana, S. erythronii, S. intermedia, S. minor, S. sclerotiorum,* and *S. smilacina* were unreactive toward dyes, dilute acids, and alkalies, because of the protective influence of fatty substances present in the walls. When such substances had been removed the hyphae could be resolved into their component parts. The outer covering was determined to be an acidic carbohydrate which responded to callose tests. Underlying the callose was a basic skeleton of chitin. The acidic character of the callose was due to an ethereal phosphate which could not be removed by dialysis. Upon hydrolysis the carbohydrate portion yielded glucose, which was identified by its specific rotation as an oxidation product of saccharic acid. It formed a phenylosazone melting at 206°C. Lecithin was separated from the fatty material. The action of bromine was very effective in breaking up the carbohydrate-fatty acid combination.—*R. C. Thomas.*

9291. **WEITZEL, WILLY. Das Rätsel des Pflanzenblutes. Enhält die Pflanze neben den Vitaminen noch andere lebenswichtige Nährstoffe? [The riddle of plant sap. Do plants contain other important life-giving nutrients besides vitamins?]** 52p. Emil Pahl Verlag f. Angew. Lebenspflege: Dresden, 1929.

9292. **WISE, LOUIS ELSBERG, and FLOYD C. PETERSON. The chemistry of wood. II. Water-soluble polysaccharide of western larch wood.** *Industr. and Engineer. Chem.* 22(4): 362-365. 1930.—The water-soluble ε-galactan of western larch, described by Schorger and Smith, yields 11.95% arabinose and 84.6% galactose on complete hydrolysis and appears to be an arabo-galactan. Over 70% of the galactose present, as indicated by analysis, could actually be separated in crystalline form. The arabinose was identified through its benzylphenylhydrazone and the diphenylhydrazone. Van der Haar's modification of Tollen's mucic acid method gives a fair approximation of the galactose content in ε-galactan hydrolysis mixtures. A modification of the Neuberg-Wohlgemuth method for arabinose furnishes a convenient proximate means of estimating this sugar. The excellent thiobarbituric acid method for furfural devised by Dox and Plaisance is admirably suited to the accurate determination of arabinose in the presence of galactose.—*Courtesy Ind. & Eng. Chem.*

BIOCHEMISTRY, METABOLISM (NITROGEN RELATIONS)

9293. **BACH, D. La nutrition azotée des Mucorinées. Assimilation des sels ammoniacaux.** *Compt. Rend. Acad. Sci. [Paris]* 184(12): 766-768. 1927.—Experiments were carried out on a large number of sp., with pH of the medium under control. Ammonium salts of strong mineral acids constitute a poor source of N, due to intense acidification of the medium. Addition of a buffer, such as Na-citrate, permits regular development of the fungi.

9294. **BJÖRKSTÉN, JOHAN, und INTO HIMBERG. Spielt Ammoniak eine direkte Rolle bei der Eiweisssynthese höherer Pflanzen?** *Biochem. Zeitschr.* 225(4/6): 441-446. 1930.—Leaves of wheat seedlings were tested for ability to form ammonia from various amids with which they were infiltrated. The quantity of ammonia split off by the parenchyma cells of the leaves was independent of the concentration of the infiltrated carbamid solutions. By etherization the ammonia produced from carbamid increased, a result to be expected from the work of Bernard, Butkewitsch, Mothes, Höfler, and Weber. Under similar conditions no ammonia was split off from acetamid and butyramid. Since as an N source for protein synthesis by wheat seedlings acetamid and butyramid are as utilizable as carbamid, it is held that ammonia does not need to play a direct rôle in the protein synthesis of higher plants; as a working hypothesis it is assumed that pyroracemic acid reacts in a special way with amids to form alpha aminoacryl acid. The presence of urease could not be demonstrated in the expressed sap or dry material of the wheat seedlings.—*Authors' summary (transl. by L. T. Leonard).*

9295. **PRIANISCHNIKOW, D. Zur Frage nach der Ammoniakernährung von höheren Pflanzen. (Vorläufige Mitteil.)** *Biochem. Zeitschr.* 207(4/6): 341-349. 1929.—Experiments were made with sugar beets, corn, and oats grown in sand to determine the effects of concentration of H^+ and of Ca and other cations on utilization of ammonia by the plant. The nutrient solution (based on Hellriegel's mixture) was kept constantly flowing through the sand, or NaOH or H_2SO_4 was frequently added to maintain a constant pH. With a neutral reaction $(NH_4)_2SO_4$ gave better growth but with an acid reaction $NaNO_3$ gave better results. Increased concentration of Ca ions in the solution increased the efficiency of the ammonia but often decreased that of the nitrate. The relative efficiency of ammonia and nitrate N is not fixed but varies with a number of external and internal factors.—*W. W. Garner.*

9296. **THOMAS, WALTER. Nitrogenous metabolism of Pyrus malus L. IV. The effect of sodium nitrate applications on the total nitrogen and its partition products in the leaves, new and one year branch growth throughout a year's cycle.** *Plant Physiol.* 2(3): 245-271. 7 fig. 1927.—These studies are an extension of the partition investigations on 2 Stayman Winesap trees of the same age, growing on sod in a homogeneous soil. One of these trees was treated in 2 applications with 20 lbs. of $NaNO_3$ and the other left untreated. In general, the present findings confirm the conclusions drawn in the previous studies and in addition indicate that the total N content of the 1-yr. (1923) branch-growth of the fertilized tree from the period of full bloom to the end of Sept. increased 10%, but the total N of the 1-yr. branch-growth of the unfertilized tree decreased 35% during this period. This lower plane of N metabolism of the untreated tree as compared with the treated tree is also indicated by the total N results of the leaves, new (1924) branch-growth, and older branch-growth. The period of most rapid absorption of the NO_3 ion is characterized by a large increase in the total water-soluble and non-protein N, concomitant with which is an increase in the amino, amide, basic, and "rest" N fractions of the fertilized as compared with the unfertilized tree in the leaves, 1-yr. (1923), and new (1924) branch-growth. From the course of the curves for total water-soluble N, non-protein N, or amino N of the fertilized as compared with the unfertilized tree it can be deduced that the 1st application of $NaNO_3$ on April 20 took 3 weeks to reach the 1-yr. branches. The same curves show that the absorption and translocation of the NO_3 ions of the 2nd application on June 6 are much more rapid, taking about 1 week only to get to the more metabolically active parts of the tree. The total water-soluble N and non-protein fraction is much higher in the more metabolically active parts of the treated tree as compared with the untreated tree throughout the whole cycle. These differences correspond to the relative vigor of the trees and must be associated with differences in enzymatic activity. The fact that the amino acid N parallels the total water-soluble curve throughout the whole cycle suggests a simplification of the N distribution problem in practical horticulture. N is stored in the fall as "amide" N and "rest" N compounds, and, as indicated by the % present during this period, is much higher in the fertilized than in the unfertilized tree. The "rest" N compounds form an important connecting link in the synthesis and degradation of proteins and there is a need for an investigation into the nature of these "unclassified" compounds whose rôle in metabolism seems so important.—*W. Thomas.*

9297. **VICKERY, HUBERT BRADFORD. Some aspects of the chemistry of green leaf cells.** *Sci. Monthly* 31(5): 408-421. 2 portraits, 1 fig. 1930.—This is a lecture,

reviewing recent work and present knowledge of the chemical composition of leaves. Particular attention is given to the proteins and nitrogenous bases, and to the work of T. B. Osborne (portrait) and of his predecessor, S. W. Johnson (portrait), on their extraction and isolation. The early history of this research, particularly in the Connecticut Agric. Exp. Station, is touched upon.

Biol.* 12: 765-772. 1930.—Hydrolysis of oroboside, isolated from *Orobus tuberosus*, with 5% H_2SO_4 yields glucose and a crystallizable nonglucosidal substance, orobol. Emulsin effects the same hydrolysis but action is extremely slow. The elementary analysis and properties of orobol were determined.—*J. S. Caldwell.*

9300. HARDEN, A., and M. G. MacFARLANE. Fermentation by yeast preparations. *Biochem. Jour.* 24(2): 343-349. 2 fig. 1930.—It was possible to reduce the rate of fermentation about 80% by means of grinding while the yeast acquired the power to respond to phosphate. Kieselguhr adsorbed the active material. The effect of various reagents on the fermentation is described.—*E. B. Carmichael.*

9301. MALYSCHEV, N. Über die vermeintliche Salzhydrolyse der Stärke. *Biochem. Zeitschr.* 206(4/6): 401-409. 1929.—Freshly prepared dilute solutions of pure potato starch or Kahlbaum's "amylum solubile" mixed with salt solutions (phosphates and chlorides) of varied concentration were placed in test tubes and kept in a thermostat at 37-45°, some of the preparations first being sterilized at 100° C. In some instances air or O was bubbled through the solutions. Progress of the hydrolysis was measured by testing at intervals with dilute I solution. In no case was a breaking down of starch observed in the sterilized solutions; in the unsterilized solutions there was some breaking down in a very few instances. Mineral salts are considered to function not as a diastatic ferment but as a co-ferment or complement.—*W. W. Garner.*

9302. MANN, P. J. G., and B. WOOLF. The action of salts on fumarase I. *Biochem. Jour.* 24(2): 427-434. 6 fig. 1930.—*B. coli communis*, washed and suspended in distilled water, produced *l*-malic acid from fumaric acid at a linear rate for the greater part of the reaction until equilibrium was established. Side reactions were inhibited by 2 or 4% propyl alcohol. The range of activity was pH 5-7.7 in the absence of added salts, with an optimum at about 6.4. Phosphates accelerated the activity at pH 6-8.8, and the optimum activity was 6.9 for *M*/5 solutions. Citrates act similarly to phosphates but have a slightly higher optimum, pH 7.1. Sulphates had a retarding effect and the optimum was about pH 6.2.—*E. B. Carmichael.*

9303. ORESTANO, G., e C. ZUMMO. Fluidificazione e saccarificazione dell'amido da parte del l'amilasi dei semi di soja. [Hydrolysis and saccharification of starch by amylases of soy beans.] *Boll. Soc. Ital. Biol. Sperim.* 5(2): 246-249. 1 fig. 1930.—Amylase is inactivated when heated for ½ hr. at 150° C. Heated at a temp. below 100°, its action rises with the temp., diminishing then gradually for temp. higher than 100°. The existence in the soy beans of 2 different enzymes, one for liquefaction, the other for the saccharification of starch, seems improbable.—*M. Comel.*

9304. ORRU, A. Azione del latice del Ficus carica sull'amido. [Action of the latex of F. carica on starch.] *Boll. Soc. Ital. Biol. Sperim.* 5(2): 176-182. 4 fig. 1930.—A diastase active upon starch occurs in the sap of *F. carica*. The optimum activity is at 50° C., and at the 2 pH values 5.3 and 6.5.—*M. Comel.*

9305. SHOJI, KENJIRO. The polarographic studies on the fermentation-products. 5. [Japanese] *Rikwagaku-Kenkyū-Jo Ihō (Bull. Inst. Phys. & Chem. Res. [Tokyo])* 9(8): 621-628. 1930; English abstract in *Abstr. from Rikwagaku-Kenkyū-Jo Ihō (Bull. Inst. Phys. & Chem. Res.)* 61-62. [Appendix to *Sci. Papers Inst. Phys. & Chem. Res.* 14(262/263). 1930.].—The quantities of reducible substances contained in "kōji" (made by growing *Aspergillus oryzae* on polished rice for the purpose of fermenting "saké") as well as in absolute alcohol, were determined by means of the polarograph. "Kōji" contains a minute quantity of acetaldehyde and also probably a very small quantity of fumaric acid.

9306. STASTNY, J. Vitaminová zkouška kvasných octů. [Vitamins of fermented vinegars.] [French summary.] *Věstník Českoslov. Akad. Zem.* 6(6/7): 611-619. 1930.—Experiments to date justify the statement that vinegar from alcoholic fermentation produced at the same time as rectified alcohol, raw or synthetic, possesses a certain amount of substances capable of influencing and activating alcoholic fermentation in a medium lacking in vitamins. The amount of these substances is proportional to the acid formed, due to the fermentation activity of vinegar bacteria. The fermentative intensity of a certain species of yeast (Logos) in a suitable seeding of cells, is a general index of the amount of this substance (Bios) present. The activity of yeasts may be better determined by measurement of the CO_2 formed, this being entirely suppressed in a medium lacking in vitamins. Fermentation tests give a negative result, however, in the presence of substances toxic to yeast, even if the latter are not toxic to the activity of vinegar bacteria. To simplify the nomenclature and method of determination of the substances produced by vinegar bacteria, substances formed equally in sterile media as well as in the other synthetic media for yeasts, these substances are called vitamin D, and the above method is considered a test for the amount of the vitamin in vinegars from alcoholic fermentation.—*Author's summary (transl. by L. O. Leuton).*

9307. HAAS, A. R. C. Oxidation-reduction indicators as a means of determining overheating in walnuts during dehydration. *Bot. Gaz.* 89(2): 200-204. 1930.—A simple and delicate method is described for the detection of "overheating" in walnuts during dehydration, in which oxidation-reduction indicators are used in buffers of approximate neutrality.—*A. R. C. Haas.*

9308. KOZŁOWSKI, ANTONI. Redukcja błekitu metylenowego przez drożdże. I. Wpływ koncentracji jonów wodorowych i temperatury. [Reduction of methylene blue by yeast. I. The influence of pH and of temp.] [With English summary.] *Acta Soc. Bot. Poloniae* 7(2): 157-163. 1930.—The reduction of methylene blue by fresh yeast is accelerated by raising the temp. to 55° C. and by increasing the pH value from 5.0 to 10.0. The optimal temp. of that reduction is near 50° C. in a neutral solution. The reducing system of yeast is affected very distinctly at 70° C., although not so markedly at 55° C. The reduction progresses very slowly and is almost indiscernible at 1-10° C.—*Author's summary.*

9309. LABROUSSE, F., et J. SAREJANNI. Recherches physiologiques sur quelques champignons parasites. *Phytopath. Zeitschr.* 2(1): 1-38. 1930.—Certain fungi, including *Thielavia basicola*, were cultivated on gelatin media to which were added suitable indicators, to demonstrate the phenomena of oxidation-reduction and changes in reaction. Some fungi develop an alkaline, others an acid reaction in the culture medium. Alkalization never coincides with the production of ammonia. The former is the resultant of strong alkalization passively developed by the fungus, entirely without

metabolic phenomena, and a slight acidification corresponding to the utilization of carbohydrates in the medium. The fungus mycelium which acidifies the medium has no passive influence on the reaction of the latter. The acidity developed depends on the nature of the carbohydrates of the medium. A fungus incapable of breaking down a carbohydrate does not change the reaction. *Thielavia basicola*, while manifesting an oxidizing power towards many of the indicators used, does not oxidize guaiacol. The order in which the indicators are reduced, with increasing difficulty, corresponds to the order of their oxidation-reduction potentials. This generalization does not hold for the fungi which alkalize the medium in their development. An abundant and dense aerial development is expressed by a more intense reducing power than a loose and reduced aerial development or than an internal development. No relationship exists between the reduction of dyes and the reduction of nitrates. The reduction of nitrates to nitrites is a characteristic common to all the alkalizing fungi studied. It does not seem possible to establish a relationship between this characteristic and pathogenicity. Changes in reaction and the phenomena of oxidation-reduction established by this technique may serve as a means of physiologically distinguishing between related sp.—*Authors' summary (transl. by T. G. Major)*.

9310. **REGEIMBAL, L. O., G. A. VACHA, and R. B. HARVEY. The effect of ethylene on the respiration of bananas during ripening.** *Plant Physiol.* 2(3): 357-359. 1 fig. 1927.—Ethylene doubles or trebles the rate of respiration of bananas for a short time, and the rate subsequently falls off below the rate of untreated fruit under similar conditions of temp. and moisture. The data seem to indicate an increase in the oxidation rate rather than simply an increase in the permeability of the cell, allowing for the more rapid diffusion of the CO_2 already present.—*L. O. Regeimbal.*

9311. **ZIMMERMAN, P. W. Oxygen requirements for root growth of cuttings in water.** *Amer. Jour. Bot.* 17 (8): 842-861. 8 pl. 1930.—Salvia cuttings formed roots at the base of the stems that were placed in 2 in. of water. Similar cuttings in 5 in. of water had a tendency to root along the stems toward the surface of the water. Cuttings in water 7 in. deep were either slow to respond or did not root at all. Cuttings aerated with O produced basal roots in shallow and deep water alike. A thin film of paraffin oil on the surface of the water prevented rooting by interfering with absorption of O from the air. Cuttings in water covered with a thin film of paraffin oil formed roots readily when the water was aerated with O. *Salix pendula* cuttings formed roots at the base of the stems when in shallow water, but when placed in deep water (8 in. or more) roots formed on the stems near the surface of the water. Cuttings in aerated water formed roots at the base of the stems and practically none at the surface of the water. A deficiency of O at the bottom of a deep water column disturbed the natural polarity of willow cuttings. Analyses indicate that willow cuttings will form roots in water if the O is 1 p.p.m. or more, this being the amount frequently found at the surface of a deep water column where roots were growing. Practically no O could be found at the bottom of a 15 in. column of water in which 10 cuttings were growing. Analyses of aerated water showed 20-30 p.p.m. at all depths. Hypertrophied lenticels were produced more abundantly in non-aerated than in aerated water. As with roots, excrescences varied from the surface of the water, becoming less and less toward the bottom of the column where the O was practically depleted. Running water was in effect equal to aeration due to the fact that the normal O content of tap water was higher than the optimum amount required by the different sp. used. English ivy required a higher O supply for root growth than willow. Where the O was 4 p.p.m. the root growth was less than where the supply was 20 p.p.m. The O supply in non-aerated water surrounding tomato cuttings varied with the depth of the water column and also with exposure to light. Cuttings in cylinders wrapped with black paper soon depleted the water of O while those in cylinders exposed to light aerated the water through photosynthesis. Tomato cuttings in deep water disintegrated readily if the cylinders containing the water were wrapped with black paper or the whole lot was kept in a dark room. Callus formed on Dorothy Perkins rose cuttings in shallow water but not in deep water. Oxidizing agents such as H_2O_2 and K-permanganate increased the amount of rooting but were not so effective as aeration.—*Author's summary.*

ORGANISM AS A WHOLE

9312. **BERKNER, F., und W. SCHLIMM. Physikalische und chemische Untersuchungen über den Einfluss der Ernte in den verschiedenen Reifestadien auf die wertgebenden Bestandteile des Getreidekorns.** *Landw. Jahrb. [Berlin]* 72(2): 269-291. 1930.—This work deals with the effect of stage of maturity on the physical and chemical characteristics of rye, wheat, barley, and oat grains. The amount of imbibitional water necessary to swell seed to the point of root emergence shows that there is no relation between specific gravity and volume of the swelled seed. Grains in the milk stage have a higher requirement for water of imbibition and show a large increase in volume during imbibition. An increase in dry matter content per 1000 grains and translocation of starch to the grains were observed as maturity progressed. The crude fat content of immature oat grains was very low, due to a lack of embryo development. All cereals studied showed a marked increase in protein content as maturity progressed. This increase was not due to the higher 1000-grain wt. of the mature stages, for it was apparent as % of dry matter.—*Authors' summary (transl. by N. A. Pettinger)*.

9313. **[BLAGOVESHCHENSKII, A. V., et al.] БЛАГОВЕЩЕНСКИЙ, А. В., и др. Опыт изучения физиологии опадения завязей у хлопчатника. [Physiology of shedding of cotton bolls.]** [English summary.] Труды Средне-Азиатского Государственного Университета, Сер. VIII-b. Бот. (*Acta Univ. Asiae Mediae, Ser. VIII-b. Bot.*) 10: 1-53. 1929.—The physiological differences between the top and the bottom of the cotton plant and between the external and internal parts were investigated. The water content of upper leaves is 61-76% of that of lower leaves. The ratio of succulence of upper leaves is also smaller than that of lower ones (0.86-0.99 and 1.00-1.12). The differences in osmotic values between internal and external parts of the cotton plant are small, but the tendencies toward increasing these values in external parts, to the end of the vegetation period, accord with a greater shedding of bolls at this time. The viscosity of sap, expressed from leaves, is greater for the internal leaves, but the differences are insignificant: 1.24 for external and 1.34 for internal. The determinations of transpiration rate by the Co paper method of Livingston gave the same results for internal as for external leaves. The mean of short diam. of stomatal aperture for internal leaves is 0.86 μ and for external 1.05 μ. The intensity of assimilation of CO_2 (Sachs-Thoday method) is greater for the external leaves in comparison with the internal (100: 46.8). The carbohydrate and N content of external leaves is greater than that of internal ones. Ringing retards the loss of carbohydrates from the upper part and on the storage of N compounds above the ring. The C/N ratio is greater above the ring. This ratio is twice as great in shedded bolls as in developing ones. This increase of the C/N ratio is caused by diminishing the N content (developing bolls 2.31-2.78%, shed bolls 1.26-1.46% of dry wt.). The invertase in external parts is less active than in internal. Oxidising ferments were not found. The physiological differences between the top and bottom and between the external and internal parts of the cotton plant are, consequently, very numerous and great and Zaitzev's hypothesis on the close relation between the shedding of bolls and their nutrition has new support.—*Author's summary.*

9314. FATTAH, M. T., and W. V. CRUESS. Factors affecting the composition of dates. *Plant Physiol.* 2: 349-355. 1927.—Mesopotamian dates were higher in sugar content than the same varieties grown in California, on the dry basis. The Deglet Noor variety was higher than other varieties in sucrose. All varieties when unripe were high in sucrose, most of which became inverted during ripening. During dehydration at 120° F. the sucrose in unripened (but mature) dates was rather rapidly inverted. Dehydration at 120° F. was the most satisfactory means of ripening dates as it not only induced loss of astringency and inversion of the sucrose but also improved the texture and appearance. Ripening was readily induced by storage in various gases and by incubation at 110-120° F. Ripening involved a rapid decrease in % of soluble tannin.—*W. V. Cruess.*

9315. FRATEUR, J. Studie op breekbaar rooggestroo. [Lodging of rye straw.] *Natuurwet. Tijdschr.* 1930(1): 2-5. 1930.—This study, which was made on an extremely brittle hybrid variety of rye, shows that the extractive substances in general, among which the pentosans predominate, incrusting the cellular membranes of the straw, are the cause of the extreme fragility of these tissues.—*J. Frateur (transl. by A. G. Plakidas).*

9316. JENSEN, P. BOYSEN. Über neue Apparate zur Messung der Kohlensäureassimilation, der Respiration, der Öffnungsweite der Spaltöffnungen und der Beleuchtungsstärke. *Zeitschr. Wiss. Biol. Abt. E. Planta* 6(3): 456-472. 7 fig. 1928.—The rate of respiration is determined by titration of $Ba(OH)_2$ solutions which are introduced into the small chamber containing the plant material. The width of stomatal opening is measured by means of the pressure required to infiltrate with water a leaf from which the air has been removed in a vacuum. Light intensity is determined for the red-yellow part of the spectrum by exposing special photographic paper, sensitive to such wave lengths, for a certain time. The standardization of this method is effected by exposing like strips of paper to light of known intensities.—*C. J. Lyon.*

9317. LEE, H. ATHERTON, and D. M. WELLER. Length of life of seed-piece roots of sugar cane and progress of the roots in the soil at different ages of growth. *Plant Physiol.* 2: 337-347. 4 fig. 1927.—During the 1st mo. of growth from the seed-piece, sugar cane obtains its nutrients from the seed-piece, and 97% of the roots developed on it are seed-piece roots and less than 3% are derived from the new stalk. At the end of 2 mo., the new roots have developed until they make up over 77% of the total, while the seed-piece roots now constitute only 22.7%. In 3 mo., the root system of the aerial shoot makes 98.8% of the total, and seed-piece roots only 1.2%. A comparison of the wt. of roots at different levels in depth was also made. During the 1st mo. 85% of the roots were in the upper 8 in. of soil. During the 2nd mo. this % drops until 50-75% of the roots are found in this layer.—*C. A. Shull.*

9318. LILIENSTERN, MARIE. Physiologische Untersuchung über Cuscuta monogyna Wahl. *Ber. Deutsch. Bot. Ges.* 46(1): 18-26. 1928.—Colorimetric and electrometric determinations of the pH of the cell saps of dodder and of various host plants led to the conclusion that the pH of normal dodder plants is 6.2-6.4. One dodder stem which had remained for 3 weeks in the dark had a pH of 5.8. Seedlings also show an acidity somewhat higher than the adults (pH 5.8-6). Various plants were tested with the view to determining whether the dodder would attack them as hosts or not, and to ascertain reasons for this. The pH of tissues of *Populus nigra* (a common host) averages 6.5. The pH of dodder used for the experiment was 6.4. Similar results were obtained with *Ribes nigrum, Polygonum hydropiper, Mentha piperita,* on all of which dodder becomes parasitic and thrives. On the contrary, sp. of *Balsomine, Echeveria, Pelargonium, Begonia rex,* and *B. primadonna,* whose tissues have cell saps of pH 6-2.6, were not attacked, and died in the attempt to parasitize them. Attempts to determine the quantity of chlorophyll in dodder were also made, employing the microspectrocolorimetric method of Lubimenko, proving that the statements of earlier authors are correct: dodder is able to develop a certain amount of chlorophyll when insufficiently nourished by the host. Peroxidase determinations (Bach and Sbarsky method) show that in parts of the stem nearest the host both enzymes are more abundant and more active than in more remote parts of the parasite. Seedlings contain more of both ferments than the older plants. The production of these 2 ferments is apparently in inverse proportion to the chlorophyll content.—*G. J. Peirce.*

9319. MIROV, T. N. Turpentining experiments with western yellow pine in northern California. *Jour. Forest.* 28(4): 521-532. 2 pl. 1930.—Analyses of oleoresin yields obtained by different methods of tapping *Pinus ponderosa* Laws. in extreme northeastern California are given, together with effects which site, form of tree, and climatic factors exert on yield. The physical constants of oleoresin from individual trees used in this study are compared with those of samples previously studied by Schorger.—*P. C. Wakeley.*

GROWTH, DEVELOPMENT, REPRODUCTION

9321. DELLEPIANE, G., e F. GIOELLI. Su di una presunta azione ormonica esercitata sull'accrescimento di vegetali da estratti endocrini. [An asserted hormonal influence exercised upon growth of plants by extracts of endocrine glands.] *Boll. Soc. Ital. Biol. Sperim.* 5(2): 243-245. 1930.—No difference in growth was observed, as compared with controls, in wheat seed upon which, before germination, aqueous solutions of extracts of endocrine glands (ovary, adrenal glands, hypophysis, etc.) had acted. Seed of various plants (e.g., legumes) transplanted after germination in media containing aqueous solutions of various endocrine glands showed less growth than controls, and but rarely the same or an increased growth. The inhibition seemed to vary with the application used. Hyacinth bulbs kept in water containing the principles of various endocrine glands showed a slower growth of roots and leaves. An hormonal specific action of the endocrine glands on the plants seems, therefore, not to exist.—*M. Comel.*

9322. KNUDSON, LEWIS. Flower production by orchid grown non-symbiotically. *Bot. Gaz.* 89(2): 192-199. 3 fig. 1930.—A *Laelia-Cattleya* hybrid, germinated aseptically (i.e., in the absence of mycorrhiza), was raised to maturity on agar in a large flask, and flowered when 8 yrs. old. Although the culture became contaminated, none of the characteristic mycorrhiza was found in the medium or in the roots, which were green and well developed.

9323. MacDOUGAL, DANIEL T. Lengthened growth periods and continuous growth. *Proc. Amer. Philosoph. Soc.* 69(6): 329-345. 1930.—Tree cambial tissue shows no seasonal rhythm. Continuous activity is possible and may be expected in evergreen trees. Growth extending continuously through more than 1 season has been observed, by means of the dendrograph, in the Monterey pine, in which growth does not take place at a cambial temp. below 8° C. *Juglans major,* native to a region with short summers and severe winters, transplanted to a place with equable climate, favorable to activity, shows a period of leaf survival and growth activity 2-3 times as long as in the original habitat. The seasonal morphogenic program in the new location shows an overlapping of activities as compared with that in the original habitat. The development of inflorescences during leaf-formation in the equable climate and long-season location suggests early attainment of high C:N ratio. Dislocation of the morphogenic program is accompanied by anatomical variations in the nut.—*F. W. Haasis.*

9324. REID, MARY E. The influence of nutritive

conditions of seeds and cuttings upon the development of roots. *Gard. Chron.* [*London*] 88(2289): 392-393. 1930.

9325. **ROBERTS, R. H. Relation of composition to growth and fruitfulness of young apple trees as affected by girdling, shading, and photoperiod.** *Plant Physiol.* 2: 273-286. 4 pl., 1 fig. 1927.—The growth of young apple trees was not correlated with the external environment, but with their internal composition. The relative amounts of such materials as carbohydrates and N compounds rather than the total amounts appear to determine the growth type and fruitfulness of the trees. Practically, the character of the growth should be used as a basis for determining cultural needs.—*R. H. Roberts.*

9326. **SIGMOND, HANS. Die Entfaltung der Blütenknospen zweier Oenothera-Arten. I & II.** *Beih. Bot. Centralbl. Abt. 1.* 46(3): 479-488; 47(1): 69-138. 8 fig. 1930.—The 1st part of the paper describes external appearance, internal constitution, and development of the buds of *O. biennis* L. and *O. lamarckiana* Sér. Blossoming may be divided into 2 periods, the 1st having to do with the slow opening and the 2nd with a series of rapidly succeeding opening movements which end in the downward bending of the calyx to the corolla. An abscission layer is formed above the ovary. The 2nd part of the paper concerns effect of light and atmospheric moisture on progress of the unfolding. Darkening 24 hrs. previous to expected time of opening restricted the process; darkening but a few hrs. previous had no effect. An exposure of 4-5 hrs. to increased humidity hastened the opening and duration of the process. Rhythmic light changes appear to be important in completion of the unfolding process, but light is not necessary as a stimulus immediately previous to opening. Lowering of temp. with correlated increased humidity, as occurs naturally in the evening, causes turgor pressure changes resulting in movements of opening.—*H. D. Hill* (*from abst. by H. Sigmond*).

9327. **WHITE, H. L. Carbon dioxide in relation to glasshouse crops. V. An analysis of the response of the tomato crop to an atmosphere enriched with carbon dioxide.** *Ann. Appl. Biol.* 17(4): 755-766. 1930.—Data are given showing that the process of enriching the atmosphere with CO_2 affects the tomato plant slightly in many different ways, the sum of these tending to an increased yield of fruit. These effects include shortening of the period between opening of the flower and picking of the fruit, high % of blossom developing into fruit, lower % of fruit retarded in ripening, better development of the truss normally most poorly developed, earlier development and ripening of trusses in the later part of the season, better swelling of the fruit at the end of the season. Conclusions are drawn that the results of an increased concentration of CO_2 are most beneficial to the plant at periods of low fruit-production. The greatest % increases in wt. of fruit of the treated plants over the controls are shown by fruits picked from trusses which develop at such periods in the life of the plant.—*Author's summary.*

GERMINATION, DORMANCY, RENEWAL OF ACTIVITY

9328. **DAVIS, W. E. Primary dormancy, after-ripening, and the development of secondary dormancy in embryos of Ambrosia trifida.** *Amer. Jour. Bot.* 17(1): 58-76. 4 fig. 1930.—The embryos of fruits of *A. trifida* are dormant at maturity; they after-ripen slowly in dry storage, but much more rapidly and completely in a saturated condition at low temp. (0°-10° C.). The time required for the after-ripening of freshly harvested fruits at the optimum low temp. (5° C.) is about 3 mo. While the fruits are at low temp. there is a slight rise in the acidity together with a pronounced rise in the catalase content of the imbibed embryos over those of air-stored fruits. If the embryos after-ripened in either dry storage or at low temp. fail to germinate when placed at high temp., due to enveloping membranes that interfere with the gaseous exchange between the embryos and the external atmosphere, they revert to the dormant condition and must again be after-ripened before germination will take place. The time required for the development of secondary dormancy in the after-ripened embryos is 30-60 days. The same embryos of fruits may be repeatedly made dormant and after-ripened by alternating periods at high temp. with sub-minimal O supply and with periods at low temp. with adequate O supply in water imbibed condition. The cause of secondary dormancy in embryos of *A. trifida* appears to be the restricted respiration at high temp., the cause of which is the low permeability to O of the membranes which envelop the embryo. The restriction of the gaseous exchange is due mainly to the influence of the nucellar membrane, consisting of a single layer of living cells immediately enveloping the embryo. While the development of dormancy is associated with restricted or incomplete respiration, the presence of a supply of O seems necessary to its development. Embryos of fruits embedded in agar, in order to reduce further the O supply to the embryos, developed dormancy more slowly than embryos of fruits at the same temp. but free from agar. During the period in which the embryos become dormant, both the respiration and the catalase activity are reduced. At the germination temp. employed, the catalase activities of fruits, seed, and naked embryos bear about the same relation to one another as does the respiratory capacity of each of these to the other.—*Author's summary.*

9329. **DAVIS, W. E. The development of dormancy in seeds of cocklebur (Xanthium).** *Amer. Jour. Bot.* 17(1): 77-87. 5 fig. 1930.—At maturity naked embryos of *Xanthium* seed exhibit no dormant tendencies. In intact seed, dormancy can be induced, at temp. suitable for germination, by imbedding seed in clay or agar, thus assisting seed coats to reduce gaseous exchange; 2 to several mo. of this treatment are required. Development of dormancy is accompanied by a fall in catalase activity and respiration intensity. Upon removal of seed coats, dormant seed under germination conditions responded variously, perhaps due to differences in seed coat permeability. Dormant seed gradually lose dormancy when kept moist at 5° C. There is a rise in catalase activity and respiration rate with loss of dormancy. In nature, seed in wet soils develop dormancy during the summer and lose it during the following winter and spring.—*A. H. Larson.*

9330. **DENNY, F. E. Chemical treatments for controlling the growth of buds of plants.** *Industr. & Engineer. Chem.* 20(6): 578-581. 5 fig. 1928.—A discussion is given of the use of certain chemicals (Na-thiocyanate, ethylene chlorohydrin, et al.) for breaking the rest period of potato tubers; of the effect of soaking tubers in thiourea, which causes the development of an unusually large number of sprouts from a seed piece, leading to an increase in the number and a decrease in the size of the tubers in the crop—a condition favorable for production of potato tubers for "seed"; of the forcing of flower buds of woody ornamentals (crab apple, lilac, *Deutzia*) in winter by chemical treatment; and of the use of chemicals (ethylene, chlorohydrin, et al.) in breaking the rest period of gladiolus bulblets.

9331. **DENNY, F. E. Sucrose and starch changes in potatoes treated with chemicals that break the rest period.** *Amer. Jour. Bot.* 17(8): 806-817. 1930.—Freshly harvested potatoes were treated with ethylene chlorhydrin, Na-thiocyanate, and thiourea, the concentrations of the chemicals being decreased from the optimum in a graded series. Press-juices from the treated potatoes obtained from the various lots at a subsequent interval, usually 4-7 days before sprouting became visible, were compared with juices from the checks with reference to sugar content. Sucrose was higher in the treated than in the check lots, and varied with the concentrations of chemicals used. No such consistent effect of the treatments on the reducing sugar content was found. When samples were taken at intervals of 24, 48, 72, etc., hrs. after treatment, the time at which the sucrose con-

tent of the treated lots became higher than that of the checks varied from 24 to 72 hrs. Samples of entire tissue which had been dried, powdered, and analyzed for starch showed that concentrations of chemical favorable for breaking the dormancy of the sprouts caused decreases in the starch; with low concentrations of chemical, however, the differences were small and of doubtful significance.—*Author's summary.*

9332. **GUTHRIE, JOHN D. The effect of various chemical treatments of dormant potato tubers on the peroxidase, catalase, pH, and reducing properties of the expressed juice.** *Contr. Boyce Thompson Inst.* 3(4): 499-508. 2 fig. 1931.—Dormant potato tubers were treated with ethylene chlorhydrin, potassium thiocyanate, thiourea, ethyl alcohol, acetaldehyde, HCN, methyl thiocyanate, acrolein, KCN, KCl, KCNO, urea, sodium chloracetate, and ethylene cyanhydrin. Peroxidase, catalase, pH, power to reduce methylene blue, and power to reduce I in acid solution were determined on the expressed juice of the tubers. No good correlation could be found between the effect of the chemical on these properties and its power to break dormancy. Those chemicals that increased the pH of the juice also increased the power of the juice to reduce I in acid solution. This increased reducing power of the juice is probably a result of the increased pH. The chemicals found to be most effective in breaking dormancy were either sulphur compounds or compounds which increased the power of the juice to reduce I in acid solution. An increase in sulphydryl compounds is probably involved in this increased power to reduce I.—*J. D. Guthrie.*

9333. **JOSEPH, HILDA C. Germination and vitality of birch seeds.** *Bot. Gaz.* 87(1): 127-151. 5 fig. 1929.—The germination of freshly harvested seed of *Betula lenta* was poor, but improved with dry storage. Air-dried seed had a narrow temp. range for germination, the minimum being 30° C. for *B. lenta*, and 20° C. for *B. populifolia*, *B. papyrifera*, and *B. lutea*. The optimum temp. for all sp. was 32° C. or 15-32° C. alternating. After-ripening proceeded best at 0-5° C. and caused a lowering of the minimum temp. required for germination. Stored moist at this temp. 4-6 weeks was sufficient to bring about excellent germination at 15° C. After a storage of 5-6 mo. at 0° C. germination occurred at 0° C. Freezing was ineffective or injurious. Germination was not affected by degree of acidity, light intensity, CO_2 concentration, or partial pressure of O. *B. papyrifera* was the first to lose viability on storage. Its optimum H_2O content for storage was 0.6%, that for *B. populifolia* 5.2%, while *B. lenta* kept well in all but very humid conditions. Viability was retained better when stored in an ice chest, irrespective of moisture content. The best time for harvesting was after the catkins had dried on the tree, but before they had opened. In making the tests, wings were removed from the seed. Conclusions are based on tests of about one million seed. The importance of after-ripening treatment in enabling the seed to germinate promptly in the early spring is pointed out.—*H. I. Baldwin.*

9334. **JOZEFOWICZ, MARY. The effect of certain treatments on the germination of tomato seeds.** *Ann. Appl. Biol.* 17(3): 504-513. 1930.—Good seed (germination power 98-99%) withstood solutions of formaldehyde, not stronger than 2% for 10 min., and not stronger than 1% for 15 min., followed by drying at 15-18° C. A 5% solution for 10 min., which was without effect when seed were sown wet, retarded the germination after drying but did not affect the vitality. Seeds of an inferior quality (80% germination) withstood solutions of formaldehyde not stronger than 1% for 5 min. when sown wet, and were affected even by 0.1% formaldehyde for 5 min. when dried after treatment. 100, 50, 35, 10, 5 and 1% solutions of H_2O_2 for 10 and 30 min., followed by drying, retarded germination, which was more pronounced with stronger solutions, the vitality of the seed being practically unaffected. An 0.05% $HgCl_2$ solution for 10 min. proved harmless, but higher concentrations and longer treatment either checked the germination of dried seed or retarded it markedly. The vitality of seed was not affected by $CuSO_4$ solutions as follows: 10% for 15 min., 5% for 20 min., 2% for 50 min., 1% for 100 min. and 0.5% for 200 min., but the germination in some cases was markedly retarded. A 5% solution for 10 min. proved practically harmless. Good air-dried seed withstood hot water at 35-46° C. for 15 hrs. and at 50.5° C. for 1 hr. without any important injury. Higher temp. decreased the % germination markedly even after 10 min. soaking. Air-dry seed were not affected by exposure to dry heat of 30-50° C. for 72 hrs. They withstood dry heat up to 79.5° C. even for 72 hrs., the germination, however, being more retarded as the temp. and time of exposure increased. Temp. above 79.5° C. proved very injurious at 10 min. exposure.—*Author's summary.*

9335. **La GARDE, ROLAND V. Non-symbiotic germination of orchids.** *Ann. Missouri Bot. Gard.* 16(4): 499-514. 1 pl. 1929.—Seed of 3 *Cattleya* hybrids were germinated in Erlenmeyer flasks on agar to which nutrient solutions of salts and sugars had been added. A new combination of salts in the solution was found superior to those formerly used. Of 4 sugars investigated, maltose gave best results, levulose, glucose, and saccharose ranking next in the order named. A pH of 4.8-5.2 was most favorable. At pH 6.0 or over, germination did not take place, or chlorosis and death followed rapidly. Reasons for the superiority of the new solution are discussed.—*H. B. Sifton.*

9336. **NIETHAMMER, ANNELIESE. Die Charakteristik der Lebenskraft verschiedenen Samenmaterials auf chemischer, physikalischer und rechnerischer Grundlage.** *Gartenbauwiss.* 1(6): 593-614. 1929.—Microchemical, histochemical, and quantitative chemical tests, determination of enzyme content, and the use of u.-v. rays, dyes, and certain mathematical formulae in judging the germination power of seed are discussed. A few of these methods were applied with negative results. It is concluded that none of these procedures are as valuable in determining the vitality of seed as ordinary germination tests.—*A. E. Murneek.*

9337. **TABATA, KIYOMITSU, RIITI KIKUTI, und ZIN'EI SASAKI. Ueber die Keimungsversuche des Pollens der Gramineen.** (Japanese.) *Proc. Crop Sci. Soc. Japan* 4: 64-76. 1 fig. 1929.—Experiments were carried out on sp. of *Hordeum*, *Triticum*, *Oryza*, *Avena*, *Secale*, *Zea*, *Setaria*, *Andropogon*, *Panicum*, *Coix*, and *Euchlaena*. Sugar (15-45%) in a dilute agar solution proved best for germination of grass pollen. Addition of stigma extract generally favored germination and increased growth of the pollen tubes. The % germination of grass pollen is low. The pollen tubes are short; their growth in length is greatest about 2 hrs. after pollination and continues for 5 hrs. There is no growth after 24 hrs.—(*Courtesy Japanese Jour. Bot. Transl. by W. Crocker.*)

TEMPERATURE RELATIONS

9338. **HARVEY, R. B. Time and temperature factors in hardening plants.** *Amer. Jour. Bot.* 17(3): 212-217. 2 fig. 1930.—The hardiness of cabbages was determined after exposure to various continuous hardening treatments and after alternation between high and low temp. The threshold value for producing hardiness in Early Jersey Wakefield cabbage was at about 5° C. Alternate equal exposures, 12 hrs. at 0° and 12 hrs. at 10° or 20°, produce greater hardiness than exposure continuously at the average of these temp. The effect of short exposure (1-4 hrs. per day) at 0° C. overbalances the effect of longer exposures (23-24 hrs.) at 10° and 20° C.—*Author's summary.*

9339. **JOZEFOWICZ, MARY. Some observations on tomato plants from seed submitted to high temperatures.** *Ann. Appl. Biol.* 17(3): 514-521. 4 fig. 1930.—The results of pre-drying seed prior to heating at high temp. and a description of abnormalities in tomato seedlings caused by heat are given. Commercial tomato seed withstood 90° C. and 88-100° C. for 1 hr. better when previously dried at lower temp., their germination being, however, markedly retarded. Part of the heated seed germinated

abnormally, and the developing plants were more or less abnormal. The primary root did not develop; the cotyledons were misshapen; and the plumule failed to develop into a normal shoot. The longer the period of pre-drying, the higher the rate of germination, and the less the degree of abnormality. The basal growing point of a tomato embryo is least resistant to heat, the apical growing point, the hypocotyl, the inner and, lastly, the outer cotyledons following in order of resistance. Embryos unable to push through the seed-coats can grow for a certain period within them and develop chlorophyll.—*Author's summary.*

9340. [SALTYKOVSKIĬ, M. I.] САЛТЫКОВСКИЙ, М. И. По вопросу о зимостойкости озимых хлебов. [Cold resistance of winter cereals.] [English summary.] Журнал Опытной Агрономии Юго-Востока. (*Jour. Exp. Landw. Südosten Eur. Russlands*) 7(2): 181-218. 17 fig. 1929.

9341. **SCHUBERT, K. Über Temperaturmessungen an der Blüte von Vinca minor.** *Ber. Deutsch. Bot. Ges.* 46 (10): 653-666. 1929.—The temp. on the upper side of the flower at times varies markedly from that on the under surface.—*S. P. Nichols.*

RADIANT ENERGY RELATIONS, PHOTOPERIODISM

9342. **CORTESE, FRANZ. Colture di actinomiceti alla luce di Wood.** *Boll. Soc. Ital. Biol. Sperim.* 5(3): 423-425. 1930.—Some sp. of Actinomyces produce, if kept in nutritive media containing meat extract, a peculiar substance, which shows a rose-red fluorescence when exposed to u.-v. light. The production of the fluorescent substance is influenced by temp.; the optimum was at 15-20° C. The red fluorescence is to be observed from the 10th day from the sowing of the culture, its intensity increasing till a maximum is reached in the 2nd mo., and thereafter slowly disappearing. The fluorescent substance was extracted, but not yet isolated.—*M. Comel.*

9343. **HIGGINS, GEORGE M., and CHARLES SHEARD. Germination and growth of seeds as dependent upon selective irradiation.** *Plant Physiol.* 2: 325-335. 2 fig. 1927.—A series of experiments was carried out on the germination and growth of seed (cucumber) using a quartz Hg lamp and vitaglass, ordinary window glass, and ultra-glass (Corning 586 A W) as filters. Data with direct irradiation by the quartz Hg lamp and on controls (no irradiation) were also obtained. The results indicate that: shorter wavelengths in general appear to stimulate while the longer wavelengths inhibit germination; wavelengths of 320-390 mμ are particularly effective in inducing growth; wavelengths of 270-320 mμ appear to inhibit, delay the time, and lessen the rate of growth; and shorter wavelengths of light act as stimulating agents which modify the control of endogenous processes and accelerate germination.—*C. Sheard.*

9344. **HUTCHINSON, A. H., and M. R. ASHTON. The effect of radiant energy on growth and sporulation in Colletotrichum phomoides.** *Canadian Jour. Res.* 3: 187-199. 1 pl., 11 fig. 1930.—The lines of the Hg arc spectrum were grouped into 3 classes on the basis of their effect on the growth of *Colletotrichum*: those which caused constant retardation; those which caused constant stimulation; and those which caused primary retardation followed by stimulation. On the basis of the effect on the production of spores, there were 2 classes of lines in the spectrum: those which hastened spore development and those which had no apparent effect. Spore production is generally hastened by monochromatic light causing retardation or extreme stimulation of growth, and is apparently not affected by light which moderately stimulates growth; moreover an optimum duration is shown for the illumination causing the accelerated development of spores. Evidence is given that the effect of monochromatic light is upon the protoplasm and not the culture. There is a marked similarity in the effect upon the growth of *Colletotrichum*, yeast, and *Paramecium*.—*T. C. Scheffer.*

9345. **MARTIN, M. T. The influence of ultra-violet radiation upon some plant cells.** *Jour. Exp. Biol.* 7: 293-307. 1930.—Very brief doses of short wave lengths of light can induce the browning of leaf surface in a variety of plants, the effect appearing after a short latent period which varies with the intensity of exposure. The effect resembles the pigmentation of the human skin on exposure to u.-v. radiation in its time relations and dosage. In the human epidermis erythema and pigmentation are produced without killing of the cells and the pigmentation is due to a protective deposition of melanin. In the plant epidermis, on the contrary, pigmentation is due to death of the epidermal cells and can be produced equally well by other agents, e.g., heat, injury, chloroform. The killing of plant epidermis is due to rays of wave length less than 2900 Å, whereas the pigmentation in the human epidermis is induced by rays of 2900-3300 Å. Moreover, the human skin reactions vary with the temp. of irradiation, whereas temp. has little effect on the response of the epidermis of *Pulmonaria* to irradiation. The experiments indicate that 2 phases are involved in *Pulmonaria:* an initial photolysis caused by the direct action of the u.-v. rays absorbed by the protoplasm and having a very low temp. coefficient, and secondary reactions thereby induced which end in the death and browning of the cell and have a high temp. coefficient.—*J. M. Robson.*

[Confirmation of the existence of mitogenetic rays demonstrated on the blastomeres of P. lividus.]** *Monitore Zool. Ital. (Firenze)* 40(4): 115-123. 1929.—Artificially fertilized eggs of *P. lividus* and roots of 5 plant spp. were used in the dark, in orange light, or diffuse daylight. In the presence of growing root-tips in appropriate positions at very short distances eggs of *P. lividus* segmented more rapidly.—*C. Maxio (transl. by J. F. McClendon).*

9347. **NAVEZ, A. E. On the alleged effect of polarized light on films of starch.** *Science* 72(1853): 13. 1930.—The author was unable to verify the results of Miss Semmens, who reported that a beam of moonlight produced perceptible hydrolysis of boiled starch. Both artificial and moonlight were used.

9348. **PORTER, C. L., and H. W. BOCKSTAHLER. Concerning the reaction of certain fungi to various wave lengths of light.** *Proc. Indiana Acad. Sci.* 38: 133-135. 1928.—*Colletotrichum lindemuthianum, Cephalothecium roseum,* and 2 *Sclerotinia* sp. were extremely sensitive to changes in quantity as well as quality of light in the visible spectrum. Ultra violet light caused greater material changes than the visible spectrum.—*H. J. Sax.*

9349. **SCAGLIA, G., e O. BUSINCO. Effetti delle irradiazioni Roentgen sull'accrescimento di Hyacinthus orientalis. [Effect of x-rays on growth of H. orientalis.]** *Arch. Fisiol.* 29(1): 48-87. 2 fig. 1930.—When bulbs were irradiated with increasing dosages of x-rays, 1 or more examples out of every group showed a greater development than the controls. The magnitude of the increase was related to the dosage employed, but the same dosages were able, acting on other subjects of the same group, to prevent or greatly delay their development and growth. The possibility of a hypersensitivity of plant protoplasm to x-rays is admitted.—*M. Comel.*

9350. **SCHWARZ, F. K., und OTMAR SCHELLENBERG. Die biologische und bakterizide Wirkung des Phosphoreszenzlichtes.** *Zentralbl. Bakt. I. Abt. (Orig.)* 116(2/3): 122-131. 3 fig. 1930.—Phosphorescent substances can absorb radiant energy in the form of short light waves and give it out in the form of cold light. Such a substance is a peculiar combination of a sulphide of an alkaline earth fused with a colorless salt (NaCl, CaF_2) and traces of a heavy metal. Various phosphorescent substances had diverse effects on the growth of plants. Plants (sprouted cress seed) subjected to phosphorescent light showed stronger growth than those kept in complete darkness; but comparison with controls in daylight was not made. Various phosphorescent sub-

stances showed different bactericidal properties for a number of bacteria, some substances being bactericidal for one bacterium or group of bacteria and not for others.

9351. [STRELIN, G. S.] СТРЕЛИН, Г. С. Действие индукции дрожжевыми культурами (митогенетических лучей) на прорастание и развитие мицелия Rhizopus nigricans и размножение Nadsonia fulvescens. [The influence of mitogenetic rays (induced by yeasts) on germination of R. nigricans and on multiplication of N. fulvescens.] Вестник Рентгенологии и Радиологии. (*Ann. Roentgenol. Radiol., Leningrad, URSS.*) 7(3): 191-197; German summary 249-250. 6 fig. 1929.—Some hanging drop cultures of *R. nigricans* on quartz cover-slips were exposed to the influence of yeast growing on agar cultures. The lengths of the hyphae were measured by means of a camera lucida, and the average determined for each phase. The hyphae exposed to any rays emitted by the yeast were approximately 25-35% longer than in the case of the controls. A total of 1391 measurements of length was made in 7 experiments, all of which gave positive results. Similar experiments were performed with cells of *N. fulvescens*, sown in hanging drop cultures. The multiplication of cells of *Nadsonia* seems to be accelerated at first, and then the effect seems to disappear. All the experiments gave a positive result, the average acceleration in multiplication of cells being 16.5%.—*A. W. Bartlett.*

9352. SUSSMANOWITSCH, HELENE. Erschöpfung durch mitogenetische Induktion. *Zeitschr. Wissens. Biol. Abt. D. Roux' Arch. Entwicklungsmech. Organ.* 113(4): 753-758. 2 fig. 1928.—Induction of an increased number of mitoses by means of mitogenetic rays causes exhaustion of reserve materials. If irradiation is prolonged beyond the necessary time for stimulation, a decrease in the number of mitoses is brought about. Using onion root as detector and yeast cells as source of mitogenetic rays, exposures of 12-26 hrs. caused a decrease of about 20% of mitoses. Fractions of a minute exposure to u.-v. light produced the same effect. The effect could be counteracted by local warming of the stimulated root, to increase its supply of reserve material.—*R. Emerson.*

HYDROGEN-ION CONCENTRATION, ELECTRICAL PHENOMENA

9353. COLLA, S. Nota sull'azione della concentrazione degli idrogenioni sulle correnti protoplasmatiche. [Action of pH on protoplasmic currents.] *Protoplasma* 5(2): 179-190. 7 fig. 1928/1929.—Protoplasmic currents in the internodal cells of *Chara crinita* L. exposed to solutions of varying pH, show variations in velocity with 2 maxima (at pH 5.3 and 7.1). The intermediate minimum currents occur in cells immersed in liquids of pH 6.2. The greatest velocity is at pH 5.3, which is almost the same as that of the cell sap. During the first 20 min. the currents in algae immersed at pH 3.2, 4.2, and 5.3 generally increase more or less gradually to a maximum before stopping completely; while at pH 6.2, 7.1, and 8.1 there is a temporary cessation during the first 5 min. after which movement again begins and increases to a maximum before ultimate cessation and death of the protoplasm. Certain variations in behavior also seem to depend upon the age and state of etiolation of the cells.—*Oran Raber.*

9354. DORRIES, W., und L. W. HAASE. Über den Einfluss der Wasserstoffionenkonzentration auf das Wachstum von Leptomitus lacteus in künstlichen Nährlösungen. *Kleine Mitteil. Mitglieder Ver. Wasser-, Boden-, u. Lufthygiene* 6(7/10): 240-244. 5 fig. 1930.—From experimental results it seems that *Leptomitus* prefers an acid reacting medium, which confirms the findings of earlier investigators. Under the conditions chosen, the pH range for its growth was pH 2.5-7.5, with the optimum 2.9-5.4. These results refer to cultures under artificial conditions, and the behavior of the fungus under natural conditions is not necessarily in absolute harmony with them. In nature, various forces affect one another and may influence growth in still another manner than that here assumed. Systematic pH measurements during the growth period of the fungus in its natural habitat seem indispensable before one can judge conclusively in practice its resistance to acids and bases. —*Authors' conclusions (transl. by W. S. Bourn).*

9355. OSTERHOUT, W. J. V., and S. E. HILL. Salt bridges and negative variations. *Jour. Gen. Physiol.* 13 (5): 547-552. 10 fig. 1930.—A negative variation in *Nitella* is unable to pass a spot killed by chloroform but can set up a negative variation beyond this spot when a salt bridge is put around it. It can likewise set up a negative variation in a cell of another plant if connected to it by 2 salt bridges.—*Authors' summary.*

9356. REIFENBERG, ADOLF, und LEA FRANKENTHAL. Über den Einfluss von Phosphatlösungen verschiedener Wasserstoffionenkonzentration auf die Atmung und Keimung von Samen. (Beziehungen zwischen Bodenreaktion und Wachstum.) *Biochem. Zeitschr.* 220 (4/6): 473-486. 1930.—Especially in green peas, and also in sugar peas, phosphates cause an increase in CO_2 output; no decline takes place until the reaction becomes strongly acid. Barley and wheat are also stimulated by phosphates, the latter only when the reaction is strongly acid. Phosphates prevent both oxidation and the release of CO_2 in oats. An increase in oxidation takes place in green and yellow peas only near the neutral point. In sugar peas both strongly acid and weakly alkaline reactions hinder the binding of O; the same is true of barley, which, however, tolerates a still stronger acid reaction. An increase in oxidation takes place in wheat only in the presence of a very weakly acid reaction; otherwise always a decrease. The optimal zone of oxidation in presence of phosphates for green seed peas is pH 6.5-7.2; for barley, pH 6.5-6.8; for oats, 3.9-6.8; and for wheat, 5.2-6.9. The respiration coefficient of peas and the grains is much raised by the application of phosphates. Although in general phosphates stimulate respiration and retard germination, the optimum for both life processes lies at the same pH of the environment, and this is in general practically identical with the optimal pH for the soil previously determined by other investigators for the given plants.—*From authors' summary (transl.).*

TOXIC ACTION

9357. BETHGE, H. Beiträge zur Frage der Empfindlichkeit von Blättern gegen schweflige Säure. *Kleine Mitteil. Mittglieder Ver. Wasser-, Boden-, u. Lufthygiene* 6(7/10): 224-226. 1 fig. 1930.—The sensitive limit of the moss lies at a concentration of about 1: 1,000,000 when this concentration persists for a day. On the other hand 1: 200,000 for several hrs. is endured without injury. For the seedlings investigated the sensitive limit thus appears to lie at a greater concentration than 1: 500,000. Moss leaves are accordingly a little more sensitive than seedlings of parsley. Generalization of these values should not be attempted until additional investigations have been made on the proportions in the air.—*Author's conclusions (transl. by L. T. Leonard).*

9358. NIETHAMMER, ANNELIESE. Die Beinflussung der Pollenkeimung unserer Nutz- und Ziergewächse durch die verschiedensten Giftstoffe, die im Pflanzenschutzdienste angewendet werden. *Gartenbauwiss.* 1(5): 471-478. 1929.—1% solution of certain spray materials was added to glucose and (less often) sucrose media in which pollen of the following plants was germinated: hazelnut, alder, *Evonymus vulgaris,* birch, *Cornus mas, Forsythia suspensa,* willow, poplar, orange, wild plum, apricot, magnolia, maple, cherry, red currant, apple, pear, chestnut, plum, lilac, azalea, peony, goldenrod, *Crataegus punctata,* and rose. "Maag," "Sulikoll," lime-sulphur, and nicotine-soap preparations did not affect germination. With few exceptions, "Dendrin," "Neodendrin," and "Thomilon" were very harmful, and lead-arsenic and "Solbar" very frequently injurious.—*A. E. Murneek.*

9359. THORNTON, NORWOOD C. Carbon dioxide storage in fruits, vegetables, and flowers. *Industr. & Engineer. Chem.* 22(11): 1186-1189. 5 fig. 1930.—Fruits

and vegetables held in storage 3-7 days withstood, without apparent injury, concentrations of CO_2 of 6-83% depending upon kind and variety. The concentration of CO_2 tolerated by each fruit and vegetable was determined at 6 storage temp. varying from 0° to 25° C. The tolerance to CO_2 was influenced by the ripeness, firmness, and freshness of the plant organ. In general, the presence of an excess of moisture in the storage chamber is undesirable. The CO_2 treatment prolonged the life of the flowers by retarding the opening of the buds. Rose-buds, when removed to warm air after a period of storage in 15% CO_2 for 7 days at 3.3° or 10° C., lasted as well as untreated roses which had been in cold storage without CO_2 for 3 days. This treatment gave a possible gain of 4 days.—*Author (courtesy Industr. & Engineer. Chem.).*

9365. **SCHMITT, F. O.** Ultrasonic micromanipulation. *Protoplasma* 7: 332-340. 1 fig. 1929.—High frequency sound waves produced by quartz crystals were conducted by fused quartz micromanipulation needles into living cells. Amoeba protoplasm can be churned up by the instrument and still form pseudopodia. Other reversible changes take place but too severe treatment leads to injury and death. If the needle touched the nucleus for a short time granules, threads and knots made their appearance. Some cases of irreversible gelation of the cytoplasm in localized areas were observed. Starfish eggs showed a whirling motion of the cytoplasmic granules around the needle and subsequent collection on the boundary of the disturbed area. This boundary underdoes violet Brownian movement indicating a highly lowered viscosity. The nucleolus can be made to describe an orbit in the nucleoplasm at varied speeds, indicating an unattached condition.—*L. Moyer.*

9366. **WILLIAMS, ROGER J.** Introduction to biochemistry. 501p. Illus. D. Van Nostrand Co. Inc.: New York, 1931. Price $4.00.—This textbook represents, in a way, a revolt against the conventional treatment of physiological chemistry which, as the author points out, is a "direct descendant of medical courses in clinical chemistry." The author has the point of view that there is much of fundamental importance to the biochemist to be obtained from a study of the chemical physiology of all types of living organisms. The scope of this book is unusually broad, embracing a discussion of the composition of not only mammals and the higher plants, but also of yeasts, molds, bacteria and unicellular animals, together with a consideration of the chemistry involved in the life processes of these organisms. The nutritional requirements of the various groups are pointed out and the mechanisms whereby food materials are rendered available are described. The subject matter is presented in a clear and cogent manner. The nature of the discussion is essentially descriptive and, as might be expected in view of the enormous mass of material surveyed, the treatment is not very detailed. Considering the worthy plan and alluring theme of this textbook, the advanced student will probably be disappointed in its admittedly "outline" character. However, the references at the end of each chapter are a valuable supplement to the discussion in the text.—*A. H. Smith.*

9367. **WILLMER, E. N.** Tissue culture from the standpoint of general physiology. *Biol. Rev. & Biol. Proc. Cambridge Phil. Soc.* 3(4): 271-302. 1928.—A review, dealing with: methods of tissue culture, and apparatus; cytological observations—character of mitochondria, fat globules, Golgi bodies, vacuome, nucleus, mitosis, etc., in tissue culture; factors governing cell size; nature of the relationship or connection between cells of a tissue (protoplasmic connections); processes of cellular differentiation, as studied in tissue culture; interconvertibility of cell types; cellular behavior and physiology as studied in tissue culture—phagocytosis, secretion by gland cells, response to drugs, etc.; and metabolism and growth, and the factors governing these processes. The bibliography includes 129 citations.

9368. **WISHART, G. M.** Groundwork of biophysics. 344p. G. Bell & Sons Ltd.: London, 1931. Price, 12s 6d.—Written to give to physicians, medical students, and others similarly handicapped, a working knowledge of physical sciences. Nearly half the book is devoted to strictly physical topics ranging from atomic structure through the physical chemistry of solutions to colloids and enzymes; the remainder is devoted to such topics as the cell, secretion, excitability, energy exchanges, work and efficiency, and certain special senses. The treatment is extremely condensed, and directed especially toward the solution of the practical problems which arise in the use of the principal physical tools of medico-physiological research. It should be useful principally as a practical guide and elementary reference book. The electrolytic dissociation of salts is discussed without reference to modern theories of complete dissociation.—*S. C. Brooks.*

9369. **REED, LOWELL J., and EMERY J. THERIAULT.** The statistical treatment of reaction-velocity

data. II. Least squares treatment of the unimolecular expression $Y=L(1-e^{-kt})$. *Jour. Phys. Chem.* 35(4): 950-971. 1931.—It was shown in a previous paper that the usual methods of calculating velocity constants are inadequate and that the least-squares procedures which have been proposed are inapplicable to unimolecular data. A statistical treatment is developed which permits of the ready derivation both of the experimental constants and of their precision values, proper allowance being made for constant errors.—*T. O. Stevens.*

(See also in B. A. 6(3): Entries 6191, 6575, 6576, 6689, 6771, 6778, 6862, 6864, 6906, 6974, 6980, 7088, 7307, 7329, 7330, 7333, 7363, 7480; and in this issue 9406, 9471, 9555, 9665, 9766, 9770, 9787, 9809, 9818, 10226, 10272, 10811, 10830, 11581)

9370. **ABDERHALDEN, EMIL, und WALTER SCHAIRER. Über das Verhalten von Dipeptiden, an deren Aufbau m- bzw. o-Tyrosin bzw. p-Nitrotyrosin bzw. Phenyl-β-alanin beteiligt ist, gegenüber n-Alkali, Erepsin und Trypsin-Kinase.** *Fermentforsch.* 12(3): 295-312. 1931.—Normal alkali had only slight action on the dipeptides investigated but quickly split a halogen acyl compound like chloracetyl-nitrotyrosine. Erepsin attacked none of the dipeptides studied whereas trypsin-kinase, free of erepsin, was effective upon glycyl- and *dl*-leucyl-*l*-*p*-tyrosine. Storage of the trypsin-kinase preparation induced certain changes in its action; *dl*-leucyl-*l*-*p*-tyrosine was more rapidly split by a 24 hr. old enzyme preparation than by a fresh one but glycyl-*l*-*p*-tyrosine was less completely converted. Such observations indicate that trypsin-kinase is an enzyme complex and unstable. The remaining halogen acyl and dipeptide compounds investigated were not attacked by trypsin-kinase.—*E. McCoy.*

9371. **ABDERHALDEN, EMIL, und EDGAR HAASE. Fortgesetzte Studien über die Abspaltbarkeit von Halogen aus Halogenacylaminosäuren und -polypeptiden durch verdünntes Alkali.** *Fermentforsch.* 12(3): 313-328. 1 fig. 1931.—The speed of cleavage of halogen from some 20 bromacetyl-amino acids and polypeptides is given. Comparison of isomeric compounds like bromacetyl-glycyl-*dl*-valine and bromacetyl-*dl*-valyl-glycine showed important differences, cleavage of the former being much more rapid. Comparison of bromacetyl-*dl*-alanyl-*dl*-leucine, -glycyl-*dl*-alanyl-*dl*-leucine, and -diglycyl-*dl*-alanyl-*dl*-leucine showed that the speed of liberation of halogen increased with the length of the polypeptide chain.—*E. McCoy.*

9372. **ABDERHALDEN, EMIL, und OTTO ZUMSTEIN. Weitere Studien über das Verhalten von Prolin enthaltenden Polypeptiden gegenüber dem Erepsin- und Trypsin-Kinase-Komplex.** *Fermentforsch.* 12(3): 341-349. 1931.—Erepsin attacked *dl*-propyl-*dl*-leucine, *dl*-propyl-*dl*-leucyl-glycine; *dl*-propyl-diglycine and *dl*-propyl-*d*-alanine only slightly; and *dl*-propyl-glycine and *dl*-leucyl-*dl*-propyl-*dl*-leucine not at all. Trypsin-kinase acted upon none of the polypeptides mentioned. Normal alkali attacked propyl-glycine and propyl-alanine but not propyl-leucine, or leucyl-propyl-leucine. From the specificity of the above reactions it is concluded that enzymes do not merely accelerate reactions but are specifically responsible for their initiation.—*E. McCoy.*

9373. **ABDERHALDEN, EMIL, und FRIEDRICH SCHWEITZER. Studien über das Verhalten von Polypeptiden, an deren Aufbau Lysin, in α- und ε- Stellung substituiert, beteiligt ist, gegenüber n-Alkali, Erepsin und Trypsin.** *Fermentforsch.* 12(3): 350-375. 1931.—Of some 25 compounds of the type in question erepsin attacked only ε-benzoyl-α-*dl*-alanyl-*dl*-lysine, ε-benzoyl-α-(*dl*-leucyl-*dl*-alanyl)-*dl*-lysine and α, ε-di-*dl*-alanyl-*dl*-lysine. To judge by the extent of the observed splitting, only the acid amide linkage in the α-position was attacked. Trypsin-kinase split ε-benzoyl-α-(*dl*-leucyl-*dl*-alanyl)-*dl*-lysine and α, ε-di-*dl*-leucyl-*dl*-lysine. Here it was obviously the leucyl group in the α-position that was attacked. Dilute alkali hydrolyzed without exception the compounds tested. In no case was the group in the ε-position attacked by the enzymes, a fact which suggests that in proteins, lysine is combined only by virtue of the amino-group in the α-position.—*E. McCoy.*

9374. **ABDERHALDEN, EMIL, und ELLA von EHRENWALL. Über das Verhalten von aus Glykokoll und Alanin aufgebauten Polypeptiden gegenüber Polypeptidasen und n-Alkali.** *Fermentforsch.* 12(3): 376-410. 1931.—Erepsin split all of the di-, tri-, and tetra-peptides tested but not such derivatives as phenylisocyanate, benzoyl-, and β-naphthalenesulfo compounds. Of the halogen acyl derivatives the following were attacked: chloracetyl-*d*-alanine; chloracetyl-*dl*-alanyl-glycine, *dl*-α-brompropionyl-glycyl-*dl*-alanyl-glycine, chloracetyl-glycyl-*d*-alanine, *dl*-α-brompropionyl-glycyl-glycyl-*d*-alanine, and chloracetyl-*dl*-leucine. An entirely trypsin-free preparation, however, attacked only chloracetyl-*d*-alanine and chloracetyl-*dl*-leucine. Trypsin-kinase split *dl*-alanyl-glycyl-*dl*-alanyl-glycine and *dl*-alanyl-glycyl-glycyl-*d*-alanine but not glycyl-*d*-alanyl-glycyl-*d*-alanine or any of the di- or tri-peptides. On phenylisocyanate and β-naphthalenesulfo derivatives there was no action. Crude extract of pancreas, however, readily attacked many polypeptide and amino acid compounds; it is therefore probable that it represented an enzyme complex. Alkali split the di-, tri-, and tetra-peptides but with differing speeds of reaction. The benzoyl- and phenylisocyanate compounds were even more quickly split than the corresponding free polypeptides. The halogen acyl derivatives were also hydrolyzed.—*E. McCoy.*

9375. **ABDERHALDEN, EMIL, und ELLA von EHRENWALL. Beitrag zur Frage der Einheitlichkeit von nach dem Verfahren von Waldschmidt-Leitz hergestellten Trypsinlösungen.** *Fermentforsch.* 12(3): 411-420. 1931.—Glycerin in the ratio of 2:1 of trypsin solution was a satisfactory stabilizing agent, effective over a number of mo. and at 1-37°C. The test substance was *dl*-leucyl-glycine, which appeared to be split by an enzyme complex. Inactivation of trypsin with time may have been due to fixation of the complex or a part of it by accessory substances in the enzyme preparation itself or to an autolytic process. With chloracetyl-*dl*-leucine and chloracetyl-*dl*-tyrosine the action of old enzyme was as strong as ever; chloracetyl-*d*-alanine was not split.—*E. McCoy.*

9376. **ABDERHALDEN, EMIL, und ERNST SCHWAB. Beitrag zum Problem der spezifischen Einstellung der Polypeptidasen.** *Fermentforsch.* 12(3): 432-461. 1931.—A polypeptidase is an enzyme for whose action an amino acid with an amino group in the α-position in the polypeptide seems to be necessary in the substrate. The erepsin complex is thus a polypeptidase. Since erepsin acted upon chloracetyl-*d*-alanine and chloracetyl-leucine it is evident that a free amino group is not essential to the action of the erepsin complex; the same was true of its action on β-naphthalenesulfo-glycyl-tyrosine. Erepsin is thus a complex of amino-polypeptidase and carboxy-polypeptidase. The same is true of trypsin and trypsin-kinase. Splitting of polypeptide isobutyl- and isoamyl-esters and the -OC-NH-linkage by trypsin-kinase are also reported.—*E. McCoy.*

9377. **BORSOOK, HENRY, DOUGLAS A. MacFADYEN, and HARDOLPH WASTENEYS. The substrate in peptic synthesis of protein.** *Jour. Gen. Physiol.* 13(3): 295-306. 1930.—Experiments are described in which the yield of protein synthesized by pepsin from a given peptic digest was highest when the hydrolyzing action of the pepsin was stopped as soon as all the protein had disappeared from the solution; the longer the digest was permitted to contain active enzyme the more the yield diminished. Exposure of the digest to pH 1.6 in the absence of active enzyme, did not diminish the amount of protein which could be synthesized from that digest. Synthesis could be effected also in concentrated solutions of isolated fractions of a peptic digest, i.e., of proteose and of peptone. The yields were approximately the same as in similar concentrations of the whole digest, though the proteins so synthesized differed in some respects from those obtained from the whole digest. The cessation of synthesis in any one digest was due to the attainment of equilibrium and not to the complete utilization of available synthesizable material. The amount of the equilibrium yield, on the other hand, depended on the amount of synthesizable material in the digest. It is concluded that the synthesizability of a given mixture of protein cleavage products by pepsin depends upon its possession of a special complex in these products. This complex appears as a result of the primary hydrolysis of the protein molecule by pepsin and is decomposed in the slow secondary hydrolysis which ensues as digestion is prolonged.—*Authors' summary.*

9378. **CALDWELL, M. L., L. E. BOOHER, and H. C. SHERMAN. Crystalline amylase.** *Science* 74(1906): 37. 1931.—From buffered alcohol-water solutions of pancreatic amylase, freshly purified, crystals were obtained which showed enzymic activity almost as high as the maximum observed in the highly purified preparations previously prepared and studied. The crystalline amylase was obtained as very minute isotropic elongated crystals which exhibited slight double refraction.

The relative observation between the enzymic power of purified enzyme solution prepared by the enzyme adsorption of aluminium hydroxide and the nitrogen content of the same solution.** *Bull. Agric. Chem. Soc. Japan* 7(1/3): 19-21. 1931.—Abstract of a Japanese paper in *Jour. Agric. Chem. Soc. Japan.*

9380. **KASE, KYOJI. Untersuchungen über die Harnstoffbildung. II. III.** *Biochem. Zeitschr.* 233(4/6): 258-282. 1931.—II. Dogs and rabbits were fasted 24 hrs., bled from the carotid, the liver perfused and washed with Ringer's solution, the large veins removed from the liver and other organs, and each reduced to a pulp. The optimum for urea formation by autolysis of the liver and from amino acids was pH 5.9. It was formed in the liver pulp by addition of amino acids (more easily from anhydride and peptide compounds than from the simpler acids); after heating the pulp, urea was not formed, but it was also formed with dialyzed liver pulp.—III. O_2 favored urea synthesis from amino acids; defibrinated blood instead of O_2 had little effect. No urea was formed from amino acids by kidneys, suprarenals, spleen, pancreas, lungs, heart, cerebrum, muscle, blood, and serum. Arginine was not decomposed. Taka-diastase and enzymes of the pancreas and intestine did not take part in urea formation, nor did it appear to be formed from ammonia in the experiments with liver pulp. Liver cells are assumed to contain an enzyme by which urea is formed from amino acids.

9381. **KOEBNER, HANS. Untersuchungen über Speichellipase.** *Zeitschr. Ges. Exp. Med.* 76(5/6): 792-803. 1931.—The saliva of a turtle, *Testudo viridis,* contained a lipase with optimal action at pH 8.2. In saliva of herbivora (sheep and cattle) the lipase was likewise demonstrable with the optimal effect in the alkaline region. These experiments again corroborate Scheer's and Fuhrberg's statement that the optimum action of lipase coincides with the pH of the saliva. Investigations were made of various physiological conditions in man. Values for the action of salivary lipase in old age were similar to those already established for infants, children, and middle aged adults. The titer of salivary lipase rose with comparative constancy in pregnancy up to delivery (more than 20 cases) and remained above normal during lactation. In patients with metabolic diseases, lipase titer decreased in diabetes mellitus (7 cases) showed no deviation from normal in a case of acetonemic nausea nor in 5 cases of various hepatic diseases (icterus catarrhalis, liver cirrhosis, calcareous occlusion, carcinoma, and Ni poisoning). No relation could be proved between salivary lipase and blood serum lipase. Results obtained with patients with metabolic disorders indicate a difference between salivary lipase and intestinal lipase.

Crystalline pepsin of Northrop.** *Science* 73(1897): 494. 1931.—From a study of the products of hydrolysis of Northrop's crystalline pepsin, it is concluded that in the main it is an individual substance but probably contains a small admixture of an extraneous protein.

9383. **MÜHLBAUER, M. Ein Modell für die räumliche Trennung von Ferment-Substrat (Diastase-Stärke) in der Zelle.** *Fermentforsch.* 12(3): 273-294. 9 fig. 1931.—It is proposed that the immunity of starch to diastase in the living cell is due to coating of the particles of both enzyme and substrate with surface-active substances such as sodium oleate, lecithin, bile salts, and cholesterin. Such a coating confers upon each unit of enzyme and substrate an electric charge, equal and repellent. The mechanism of covering and release of the system is reversible and is effected by change of H- or OH-ion concentration or the appearance of alcohol and probably other substances within the cell. The case of starch-diastase is to be taken merely as a model; the particular surface-active substances investigated were without effect in the casein-pancreatin system.—*E. McCoy.*

Phys. et Math.*) 6(1): Збірник Праць Біологічного Інституту. (*Trav. Inst. Biol.*) 2: 155-177. 1927.—Determinations of the catalase index in a single sample of blood gives no clue as to the relationship between it and hemoglobin content; also, there is no regularity in the catalase variations over several days. By determinations made every 15-20 min. a correlation with the contracting empty stomach can be demonstrated. In one day the catalase index may range from 0 to 16.7. The zero indices cannot always be discovered by random determinations but are frequent in some cases. Zero values correspond to continuous contractions of the "acid" character. In connection with Kolzow's hypothesis of hereditary groups on the basis of catalase indices, repeated deter-

minations on an individual would place him in any or all groups. Catalase content of blood can only be interpreted after a number of successive determinations. The variations in other enzymatic secretions must be studied as well. The hemoglobin content is stable during these variations.—*W. M. Sandstrom.*

9388. RONA, P., und R. ITELSOHN-SCHECHTER. Über die Spaltung des Milchsäureäthylesters durch Leberesterase. *Biochem. Zeitschr.* 203(1/6): 293-297. 3 fig. 1928.—The esterase of swine liver hydrolyzed ethyl-*d*-lactate more rapidly than the *l*-lactate or the racemic *dl*-lactate.—*O. Bodansky.*

Zeitschr.* 217(1/3): 34-41. 1 fig. 1930.—Experiments in which solutions of *d*-, *dl*- and *l*-lactic acids (about 0.06*M*) were each warmed in sealed tubes with 40 cc. amyl alcohol and 0.6 gm. pancreas powder for various periods, showed that the amyl ester of *d*-lactic acid was formed more quickly than that of the *dl*-acid and that that of the *l*-acid formed most slowly.—*A. M. Smith.*

9390. RONA, P., R. AMMON, und M. WERNER. Die stereochemische Spezifität der Takaesterase. *Biochem. Zeitschr.* 217(1/3): 42-49. 1 fig. 1930.—The dissociation constant of the compound of taka-esterase with *d*-mandelic acid-methyl ester was 0.00,289 ($10^{-3.26}$); with the *l*-ester it was 0.000,556 ($10^{-2.64}$). The ratio between the hydrolysis dissociation constants was about 1:2.09. Taka-esterase had about 5 times the affinity for the *d*-ester as for the *l*-ester. The rate of hydrolysis of the *l*-ester-enzyme compound was about twice as great as that of the *d*-ester-enzyme compound. The optical specificity of taka-esterase action was exhaustively discussed since the individual hydrolysis reactions of *d*- and *l*-ester in the decomposition of the racemate are quantitatively obtained from the 4 dissociation and reaction velocity constants found.—*N. M. Payne.*

9391. ROSENTHAL, OTTO. Untersuchungen über Milchsäuregärung von Warmblutergeweben. II. Einfluss der Kalium- und Calciumionen auf das Zustandekommen der Extragärung von Speicheldrüsen- und Lebergewebe der Ratte. *Biochem. Zeitschr.* 211(4/6): 295-322. 12 fig. 1929.—K and Ca ions exerted essentially the same effect on the occurrence, in both hepatic and salivary gland tissue of the rat, of extrafermentation [defined in a previous article as the excess fermentation obtained by submitting the organ to aerobic conditions for 1 hr. at 37.5°, before depriving it of O, over what was obtained if the tissues were deprived of O immediately on removal from the body]. Absence of K and Ca during the aerobiosis either nullified or greatly limited the occurrence of extrafermentation. The cation effect was reversible; both cations were concerned in it. The only difference between the 2 tissues in this respect was that, with liver, Ca produced a more abundant extrafermentation than K; with salivary gland tissue the 2 cations produced the same average amount of fermentation, but after treatment with Ca the initial rapidity of fermentation was greater and the decrease sharper than after K. The parallelism of the cation effect on the liver and submaxillary gland suggests a like mechanism of extrafermentation in both tissues, and contradicts an earlier hypothesis that the extrafermentation of liver tissue is due to the splitting of an especially unstable intermediate sugar formed during aerobiosis, while extrafermentation of salivary gland tissue is due chiefly to an increase of fermentability during aerobiosis. The most probable explanation of the phenomenon in both involves an activation of fermentative capacity which has nothing to do with the substrate (cellular carbohydrate in the liver, glucose in the submaxillary). This was apparent from the fact that aerobiosis in salivary gland tissue, even in an optimal medium (so far as its ionic composition was concerned) did not reach its extreme activity without addition of glucose. Hence it may be deduced that the regular non-occurrence of extrafermentation in the liver of starved rats was due in part to the ineffectiveness of aerobiosis caused by the lack or the decrease of the substrate. Hitherto it was believed that enzyme activation took place in starved rats but could not produce an effect for lack of enzyme material. The influence of glucose on the occurrence of extrafermentation of salivary gland tissue certainly cannot be due to the production during aerobiosis of a more readily fermenting intermediate sugar from glucose. If glucose action is due to the formation of an intermediate sugar (a possibility which cannot be excluded), such intermediate is to be regarded only as an enzyme activator, not as a substrate.—*Author's summary (transl. by H. J. Vonk).*

9395. ALDRICH, L. B. A study of body radiation. *Smithsonian Misc. Coll.* 81(6): 1-54. 9 fig. 1928.—The "melikeron" previously described was used to determine the radiation from the unclothed surface of the body and from the clothes, while simultaneous temp. determinations of these areas were obtained with a thermocouple. The author concludes that "the radiation from the skin and clothing is approximately that of a black body or perfect radiator." Heat loss of a clothed subject at rest indoors at usual temp. with no air movement is distributed thus: evaporation 24%, radiation 46%, convection 30%. At a distance of 30 cm. the heat of the body has no effect on the thermocouple. Loss by radiation increases about 2 fold when room temp. is lowered from 26 to 15°. The effect on radiation of normal fluctuations of humidity is negligible.—*B. McGlone.*

9396. BARCROFT, J., and J. J. IZQUIERDO. The effect of temperature on the frequency of heart and

respiration in the guinea-pig and cat. *Jour. Physiol.* 71(4): 364-372. 1931.—Using 14 cats (1.6-3.4 kgm.) and 3 guinea pigs (400-600 gm.), some deeply, the others lightly anesthetized, the authors conclude that between 25 and 41° C. in deeply anesthetized cats the pulse rate and respiration rate rise gradually with the temp. In lightly anesthetized cats: (a) The same is true at low temp. about 33 ± 1.5° C. Between that temp. and 38.5 ± 1.5° C. there is a region in which the relation of the pulse rate to the temp. is irregular. There is often a fall of pulse rate as the temp. rises and vice versa. The respiration rate reacts frequently in the same way. (b) In the region between 38.5 ± 1.5° and 41° C. the pulse rate rises with the temp. and the respiration rate rises very rapidly. (c) The irregularities of the pulse rate are not abolished by doses of atropine sufficient to paralyse the vagal nerve endings in the heart. (d) These irregularities are coincident with and are probably associated with shivering and the general syndrome of "sham rage." To that extent there is evidence of their being associated with the sympathetic supply of the heart.

9397. **COBLENTZ, W. W., R. STAIR, and J. M. HOGUE. The spectral erythemic reaction of the human skin to ultraviolet radiation.** *Proc. Nation. Acad. Sci. U. S. A.* 17(6): 401-405. 1931.—Radiation from a quartz Hg lamp was passed through a large monochromator, and through an exit slit so adjusted as to allow isolation of a narrow band of wave lengths. Erythemic response of human skin to various wave-lengths in the U.-V. spectrum was measured by adjusting the slit so as to allow the radiation from a particular region of the U.-V. spectrum to fall on the untanned skin of the arm, just long enough to produce a perceptible and brief (24 hrs.) erythema. Readings of the minimum time of exposure required to produce such an erythema, at different wave-lengths, give a curve which shows that the erythemic response is nil at below 313 mμ; increases rapidly with decrease in wave-length, reacting a maximum (taken as 100) at around 297 mμ, and falling sharply to a minimum at around 280 mμ; to this point, the present data agree admirably with those of Hausser and Vahle and of Luckiesh, Holladay, and Taylor; at wave-lengths shorter than 280 mμ, the erythema response increases rapidly with decrease in wave length, but the present data show a much more gradual increase of sensitivity, and a lower value at 250 mμ, than the data of the other investigators. Reducing the intensity (by a glass filter) to ¼ when exposing 4 times as long gave, at 279 mμ, substantially the same effect as the standard intensity and duration. To produce minimum perceptible erythema on 1 sq. cm. of untanned skin, using monochromatic radiation of 297 mμ, required about 500,000 ergs. The authors comment on the need and difficulty of devising a standard unit of radiation, and an inanimate dosage-meter.

9398. **EFIMOFF, W. W., P. P. MITROFANOFF, M. N. SARCH, A. I. LEWINA, A. P. KRJUTSCHKOWA, N. A. ITINA, und W. A. POCHWALENSKY. Die physiologische Rationalisierung der Arbeitsordnung bei verschiedenen Berufen. I. Untersuchungen über den physiologischen Einfluss von physischer Arbeit bei sehr hoher und bei mässiger Umgebungstemperatur, besonders bezüglich der Arbeitszeit.** *Arbeitsphysiologie* 3(3): 207-217. 1930.—The problem was to investigate the influence of the extraordinary external temp. (70-135° C.) upon the workmen who were engaged in cleaning the furnaces at night of the Moscow street railroad stations. The pulse rose to 216 per min., the maximum blood pressure to 165 mm. Hg, the minimum blood pressure to 0, and the body temp. to 38.4°. The length of the recovery period to normal values required 25-45 min. By allowing the furnaces a longer time to cool before beginning the cleaning, it was possible to lower all of the physiological values and to shorten the periods of recovery. The moderate temp. of the furnace after the longer cooling was usually under 60° whereas the higher temp. was 100° or over. The best methods for the study of the workers under conditions of high external temp. were measurements of pulse frequency, maximum and minimum blood pressure, blood viscosity, and body temp. The best arrangement of work and recovery periods was for high temp. 5 min. work and 25 min. recovery; for moderate temp., 15 min. work and 15 min. recovery.—*T. M. Carpenter.*

9399. **FARDON, J. C. Infra-red absorption spectra of biological materials.** *Bull. Basic Sci. Res. [Univ. Cincinnati]* 2(1): 72-81. 8 fig. 1928.—Infra-red absorption spectra of cod-liver oil, aniseed oil, lemon oil, cinnamon oil and gelatin were obtained and the absorption curves plotted. These show in every case a decided absorption peak at 3.5 μ supposedly due to the CH_3-groups present.—*J. L. Cameron.*

9400. **FEDERIGHI, H. Temperature and the heart beat in Nereis virens Sars.** *Jour. Exp. Zool.* 56(4): 393-406. 1930.—The temp. characteristics for the frequency of heart beat are μ=8,300, 11,400, 13,700, 16,400, 21,900, and 24,300 calories. These different values for μ obtained from animals apparently alike indicate that there exists some modification in the pacemaker mechanism of the separate animals. Furthermore, all these characteristics (μ) are interrelated in that they are similar to those already reported as commonly associated with respiratory processes. Two critical temperatures are reported: 10° C. and 13° C.—*Author (courtesy Wistar Bibl. Serv.).*

9401. **GAERTNER, OTTO. Die Durchlässigkeit der menschlichen Haut im Gebiete von 0.3-2.0 μ.** *Strahlentherapie* 40(2): 377-382. 1931.—With 0.8 mm. sections of cadaver skin permeability was greatest at 1.5-0.7 μ and little dependent on wave length. The permeability decreased more rapidly above 1.5 μ than toward the violet. In violet and ultraviolet there were pronounced individual differences, while between 1.5-0.7 μ the behavior was, in general, the same.

9402. **GUERRINI, GUIDO. Sull'azione della luce filtrata attraverso schermi colorati. [Action of light filtered through colored screens.]** *Arch. Fisiol.* 29(3): 356-368. 1931.—Light filtered through transparent colored screens, especially red and yellow, increased the hemolysis by saponin. Long wave spectrum radiations also stimulated glucose fermentation by *Saccharomyces,* the activity being stronger when longer wave rays were filtered through the screens.—*M. Comel.*

9403. **KARTSCHAGIN, W. A., und G. S. WARSCHAWER. Die Stärke des äusseren photoelektrischen Effects des menschlichen Körpers in Abhängigkeit von der spektralen Zusammensetzung der einwirkenden Strahlung.** *Strahlentherapie* 40(1): 174-188. 1931.—By a special method the authors investigated the photoelectric effect of the human body during irradiation with a mercury-vapor lamp. Rays filtered through ordinary glass produced no photoelectric effect; with rays filtered through blue uviolglass it was slight; during irradiation with unfiltered U.-V. rays it amounted to 0.65 of the same effect of iron under similar irradiation. Furthermore, the photoelectric effect of the skin from U.-V. rays filtered through blue uviolglass was equal to 0.51 of the iron effect with similar rays filtered through uviolglass. The photoelectric effect of Fe with rays from the quartz lamp filtered through uviolglass was equal to only 0.017 of the same effect of Fe irradiated with unfiltered rays of the quartz lamp. The external photoelectric effect of the human body irradiated with quartz lamp rays filtered through uviolglass was equal to 0.009 of photoelectric effect of iron with similar, though unfiltered rays; it was only 0.014 of the similar photoelectric effect of the human body under the influence of unfiltered rays of the mercury-vapor lamp.

9404. **KAWAKAMI, TOKIJI. Veränderungen im Kohlehydratstoffwechsel. II. In: LUDWIG PINCUSSEN. Über Veränderungen des Stoffwechsels unter Bestrahlung. V.** *Biochem. Zeitschr.* 208(1/3): 185-190. 1929.—A significant increase in the glycogen contents of the liver and muscle of rats with a corresponding decrease in the lactic acid contents was obtained after irradiation.

This confirms previous work on the changes observed after irradiation in the glycogen, blood sugar, and lactic acid values. No change was noted in the glycogen and lactic acid contents of the heart and skeletal muscle when exposed in the form of thin sections to the action of the Hg arc lamp.—*L. G. Wesson.*

9405. KELLER, PHILIPP. Die lichtbiologischen Grundlagen einer Ultraviolett-Lichtdosimetrie. *Strahlentherapie* 34(1): 129-142. 4 fig. 1929.—The complexity of the biological relationships makes the determination of U.-V. dosage especially difficult. Although the U.-V. erythema by no means accurately parallels the other effects either quantitatively, that is with respect to dosage, or qualitatively, with respect to the effective wave lengh band, it must be accepted as being the easiest and most exact of the observed phenomena fundamental for the determination of dosage. However, it cannot be possible that the Hausser-Vahle sensitivity curve for the determination of the skin sensitivity can be analogous to a method of measuring dosage, since the effect of certain wave lengths on the skin varies with the thickness of the horny layer as well as with the time in which the erythema is observed and with its intensity. The intensity of the erythema is a factor insofar as greater heightening of the erythema is produced by smaller changes of intensity of the longer waves as compared to the shorter. Of the methods of dosimetry available at the present time, the iodide method modified by Keller, the paraphenyl method of Saidman, and the cadmium cell with suitable filters in some measure parallel the erythema production of light. The ionization method is suitable for the short waves, the method of fluorescence for the long waves.—*P. Keller (transl. by H. S. Mayerson).*

9406. KOEPPE, HANS. Licht und Katalase. *Strahlentherapie* 34(3): 598-604. 1929.—Since light and catalase alike have the property of breaking up H_2O_2 into H_2O and free O, Koeppe sought to measure (1) the intensity of U.-V. irradiation and (2) the response of blood, by the action of the rays in the one case and the blood catalase in the other on H_2O_2. A suitable concentration of H_2O_2 solution was found to release in a given unit of time under a given irradiation a constant amount of free O. Thus, a single burner of a quartz mercury lamp which at a distance of 35 cm. irradiated a surface of 4 cm² of 30% H_2O_2 solution for 50 min. released 1.8 cc. of O every 5 min. This, after calculation of the value of the short wave rays used (in this case, less than 400 mμ), permitted a reckoning of the intensity of the action of the rays. The difference between the action of U.-V. rays and catalase on H_2O_2 is that the catalase acts only for a limited time; otherwise the effect is the same. The author concludes that catalase is an accumulator, a storage battery, as it were, for radiant energy, and that, instead of being oxidized and destroyed by high H_2O_2 concentrations, the energy content of the catalase is exhausted. The so-called guaiacol test, in which a rose-colored ring is produced in a weak guaiacol solution either by a blood solution with a few drops of H_2O_2 solution or by U.-V. rays, would support this hypothesis if blood and catalase were the same. Catalase alone, however, will not oxidize guaiacol, but peroxidase (which is also present in the blood) will. The theory must therefore be enlarged. Only certain ferments, and certain rays, have the power to break down H_2O_2; these rays transform a certain substance, which has the power to store radiant energy, into a certain ferment. Likewise, only certain rays and certain ferments have an oxidizing action. Possibly some rays have both actions.

9407. LEA, COLIN H. The effect of light on the oxidation of fats. *Proc. Roy. Soc.* [*London*] B 108(756): 175-189. 7 fig. 1931.—A new method for determining the active O content of fats is described. To the fat (1 gm.) is added powdered KI (1-2 gm.) and glacial acetic acid-chloroform mixture (2:1 by volume, 19 cc.). The air is displaced by N and the tube heated until chloroform vapor issues from the hole in the rubber stopper. A glass plug is inserted, the tube cooled, the contents poured into dilute KI and titrated against $N/500$ thiosulphate. It is advisable to carry out the determination by artificial light. Using the above and a quantitative modification of the Kreis test the oxidation of beef fat was shown to be sensibly accelerated by weak artificial light, while exposure for a few min. to direct sunlight was sufficient to produce rancidity. The reaction is autocatalytic and even brief exposure to light accelerated subsequent oxidation. Bleaching of the yellow pigment appeared at a comparatively early stage of the oxidation. The relationship between response to the Kreis test and the active O content of the fat varied with the temp. To compare the relative susceptibilities of fats to oxidation the samples are irradiated by the same lamp (100 watt at 3 ft. distance) in a constant temp. room at 25° C. and the oxidation followed as above.—*C. H. Lea.*

9408. LUDWIG, FRITZ, und JULIUS von RIES. Über den Einfluss der Rot- und Blaustrahlen auf das Wachstum. *Strahlentherapie* 39(3): 485-489. 1 fig. 1931.—Previously it had been shown that red light is the antagonist of U.-V. light. An unstated number of pregnant rats (that young might be continuously subjected to one kind of light) were placed in cages to which blue or red light only was admitted (controls under window glass). The young under red light showed accelerated development (80 gm. heavier than controls); those under blue glass developed faster than the controls but were much inferior to those under red glass. Using the same cages over plants, similar results were obtained. Accidentally an ant hill was found under the red glass; when covered with the blue glass, the ants migrated the following day to the red cage. Red light may have a bearing on the growth vitamin.

9409. MENNESHEIMER, ALOIS M., und R. MATTHAEI. Beobachtungen über die Pigmentierung der Haut. *Strahlentherapie.* 35(2): 339-352. 1 pl., 3 fig. 1930.—The authors studied the pigmentation of a definite skin area under the influence of solar radiation. The resulting pigments were defined according to Oswald's scheme by an exactly described method which uses a rotating color disk, by which each shade between the standard colors could be assigned its place in the Oswald system. Massaging of the skin in remote areas increased the pigment formation in the observed skin area. Thus it was demonstrated that the ability of the skin to form pigment can be enhanced by therapeutic treatment not directed on the irradiated area.—*A. M. Mennesheimer (transl. by H. S. Mayerson).*

9410. RENTSCHLER, L. B. The effects of ultra-violet light on Paramaecium. *Science* 73(1896): 480-481. 1931.

9411. SCHNEIDER, HERMAN, and GEORGE SPERTI. The quantum theory in biology. *Bull. Basic Sci. Res.* [*Univ. Cincinnati*] 1(1): 7-33. 11 pl. 1926.—Reasonably stable ultra-violet filters with sharp absorption limits ranging at small intervals from 2030-3660 Å were prepared by use of the proper concentrations of solutions of the following compounds: $(NH_4)_2SO_4$, $SrCl_2$, $CaCl_2$, acetic acid, lead acetate, $CuSO_4$, $CuCl_2$, and $AlCl_3$ with $CuSO_4$. By use of these it was found that certain inorganic and organic compounds are formed or decomposed, and bacteria and protozoa are killed, at frequencies equal to or greater than certain critical frequencies of ultra-violet. Critical wave-lengths were found to be as follows: for the decomposition of KI, 3340 Å; the formation of ozone, 1860 Å; the inactivation of the enzymes rennet and pepsin, 2370 Å; the inactivation of invertase, 2480 Å. Within the accuracy of the filters used, all the living materials studied (the bacteria *B. coli communis* and *B. subtilis,* and the protozoa *Uroleptus mobilis* and *Blepharisma arisma euglena*) were destroyed at the same critical wave-length, 2750 Å. This indicates the possibility that the same compound in all was attacked. The quantum theory, or at least a very similar theory, is applicable to the biological effects of radiations. Critical frequencies afford a means of stating these biological effects mathematically.—*J. L. Cameron.*

9412. SCHULTZER, POUL. Über die substituierenden Eigenschaften langdauernder Ultravioletbestrahlung bei experimenteller Rachitis. *Biochem. Zeitschr.* 211 (4/6) : 445-453. 2 fig. 1929.—Daily irradiation for 10 min. with an U.-V. lamp at 1 meter distance prevented rickets in rats fed on McCollum's diet number 3143. The non-irradiated controls developed the rachitic symptoms of swollen costal cartilages, deformed thorax, wide epiphysial lines, low serum phosphorus, high water content of the tibia and low body weight. The irradiated rats showed no bone deformation, narrow epiphysial lines, normal serum phosphorus and water content of the tibia, while some showed a slight histological osteoporosis. —*A. Hemingway.*

9413. STANLEY, WILLARD F. The effect of temperature on vestigial wing in Drosophila melanogaster, with temperature-effective periods. *Physiol. Zool.* 4 (3) : 394-408. 1931.—An unselected inbred strain of the vestigial-winged mutant was raised under controlled conditions at 11 constant temps. ranging from 15 to 31° C., and the temp. effective period for wing length determined for 17° and 27° C. by the method of transfers at short intervals. The length of vestigial wing varies directly with the temp., but not in exact proportion. The sexual dimorphism of wing length is not consistently in one direction, but is dependent on the specific temp. The critical temp. for wing length, as determined by extreme changes in wing length and by range of variability, occurs between 29.5 and 30.3° C. for the ♂♂ and between 30.3 and 31° C. for the ♀♀. At these temps. there are manifested also changes in wing width, in the carriage of the wings, and in the angle of elevation of the postscutellar bristles. The temp. effective period for wing length occurred during early larval life, and at the temps. used the length of this period was approximately proportional to the larval period and to the entire developmental period.—*Author (courtesy Wistar Bibl. Serv.).*

9414. STEINER, KARL. Über die Wirkung kombinierter Röntgen- und Ultraviolettlichtbestrahlung. (Experimente an der Hornhaut von Salamanderlarven.) *Strahlentherapie* 39 (3) : 500-506. 1931.—Three series and 38 groups of experiments were done on the salamander cornea: I. preliminary x-ray irradiation, followed by U.-V. irradiation: II. irradiation with U.-V. followed by x-ray irradiation: III. as controls, irradiation with U.-V. alone. In I and II 1 H, 4 H, and 12 H were used, always with ½ mm. Al; 3 min. U.-V. was given at 60 cm., or 5 min. at 30 cm. The after-irradiations with x-rays were done at various times and intervals; with preliminary x-ray irradiation, early and late periods of the secondary reaction were taken into consideration. Ordinarily 2 larvae at a time were fixed at periods of 15, 30, 45 min., 1, 2, 4, 6, 8 hrs., 1, 2, 4, 8, 16, 30, and 60 days after the last irradiation. It was found that the 2 reactions occurred concomitantly, never having a cumulative effect (sensitization), but only one of summation.

9427. **HENRIQUES, O. M. Die Dissoziationskonstanten der Gallensäuren.** *Acta. Path. et Microbiol. Scandinavica Suppl.* 3: 141-149. 1930.—A simple colorimetric method has been developed for titration of acids and bases which are soluble in alcohol but sparingly soluble in water. Titration is performed in mixtures of water and alcohol; from data obtained in this way the dissociation constants are calculated and the values for pure water extrapolated. The following values for pK water (18° C.) were found: glycocholeic acid, 2.46; glycocholic acid, 2.78; taurocholeic acid, 2.93; and taurocholic acid, 3.23.—*O. M. Henriques.*

9428. **HOFMAN, J. J., en J. de KEUNING. Suikerbepaling in urine met den glukophot. [Determination of sugar in urine with the glucophot.]** *Pharmaceut. Weekblad* 68[e](26): 584-589. 1931.—A volume of urine is boiled in a tube in a water bath with a certain volume of a 7% solution of NaOH. The yellow-brown colour is compared with a scale of yellow to brown liquids in the apparatus. Solutions of glucose, samples of urine containing glucose, and samples of urine containing glucose and albumin were examined in this way. The method was compared with the titrimetric and polarimetric methods. It is concluded that the glucophot is usable but the titrimetric and polarimetric methods are more exact.—*J. J. Hofman.*

9429. **INGRAM, W. WILSON, and G. V. RUDD. The estimation of urea in blood.** *Med. Jour. Australia* 1(25): 775-776. 1928.—To prepare urease, wash 3 gm. "permutit" with 2% acetic acid and twice with water. To moist "permutit" add 100cc. 15% ethyl alcohol and 5 gm. jack bean meal. Shake continuously for 15 min., filter. Filtrate contains urease which gives accurate results. Keep in ice box. Myers' and Maclean's methods for urea were used. Urea values were compared to N. P. N. of normal and nephritic bloods.—*M. R. Freeland.*

9430. **ITANO, ARAO. Investigation on antimony electrode for determination of hydrogen ion concentration. I. Standardization of an antimony electrode in buffer solutions and calculation of pH.** *Ber. Ōhara Inst. Landw. Forsch. Japan* 4(2): 273-277. 1 fig. 1929.—A comparative study was made of H and Sb electrodes in Clark's and Kolthoff's buffer solutions. A formula, $pH = (E - 0.104)/0.054$, based on Franke and Willaman equation ($E = 0.050 - 0.054$ pH, at 25° C.) can be used satisfactorily for the chain and conditions noted previously. The Sb electrode used in this investigation gave readings close to those obtained by the H electrode in both Clark's and Kolthoff's buffer solutions. Somewhat larger variations were noted in alkaline solutions, which will be investigated further together with other factors as manner and duration of shaking, and condition of the electrode. In general, with shaking by hand an equilibrium was obtained at the end of 1 min.—*Author's summary.*

9431. **JENSEN, H., and A. DeLAWDER. Studies on crystalline insulin. IX. The adsorption of insulin on charcoal.** *Jour. Biol. Chem.* 87(3): 701-712. 1930.—The treatment of several insulin preparations—pyridine ppt. (Squibb's), crystalline insulin, pig insulin—by Dingemanse's procedure of adsorption on charcoal and extraction with phenol, failed to give a product more active than crystalline insulin. Dingemanse's work was repeated using the same insulin (organon) and the same charcoal (medicinal supranorit) and in no case was a product more active than crystalline insulin obtained. Dingemanse's report that her final product from organon insulin is unstable in solution or dry form was substantiated; however, crystalline insulin loses none of its activity on similar standing. The authors can offer no explanation of Dingemanse's findings except perhaps a failure to make an absolute comparison in standardization.—*H. Jensen.*

9432. **KADRNKA, SILVIJE. Hepatosplenographie. Röntgenologische Darstellung des Parenchymas der Milz und Leber durch ein neues in die Blutbahn eingebrachtes kolloidales Kontrastmittel (Thorotrast).** *Fortschr. Geb. Röntgenstrahlen* 44(1): 9-15. 10 fig. 1931.—Thorotrast (25% thorium dioxide solution containing 22% thorium metal) was diluted at least 10 times with 5% glucose and injected intravenously in increasing doses of 0.10 or 0.05 gm. thorotrast per kgm. followed by x-ray examinations 24 hrs. later; usually 0.80 gm. was sufficient to make the liver and spleen visible, or ½-¾ of that if only the margins were desired. The negative colloidal thorium particles were stored in the reticular cells of the splenic medulla and in the Kupffer cells; storage occurring in the bone marrow and lungs and after heavy dose in the suprarenals was too scant to leave a shadow. With these doses animal experiments showed no cell changes within a limited period. Hemoglobinuria observed in rabbits was not observed in man; there was a slight, transient decrease in erythrocytes.

9433. **KILPATRICK, MARTIN, Jr., and ELWYN F. CHASE. The electrometric and catalytic determination of hydrogen-ion concentration. The mean activity coefficients of the ions of benzoic acid in potassium chloride solutions.** *Jour. Amer. Chem. Soc.* 53(5): 1732-1744. 3 fig. 1931.—The pH of a series of benzoatebenzoic acid buffers in KCl solutions was determined by 2 independent methods. The catalytic method gave results which agree with those obtained by the quinhydrone electrode. In both cases a proper consideration of "electrolyte (salt) effects" is necessary. From these determinations,

the solubility of benzoic acid in water and the values for the dissociation constant of benzoic acid at zero electrolyte concentration, and the mean activity coefficients of the ions of benzoic acid have been evaluated. The results in KCl solutions are compared with those in NaCl solutions.—*M. Kilpatrick, Jr.*

9434. **KLAUER, H. Bestimmung von Alkohol in Blut und Gehirn.** *Deutsche Zeitschr. Ges. Gerichtl. Med.* 17 (2): 89-91. 1931.—The author gives a simple method of obtaining a very pure distillate, even of old blood, urine, and brain, for use in the usual methods of alcohol detection; and a modification of the method of determining alcohol by $K_2Cr_2O_7$ in Schwarz' modification of Nicloux method, heating being eliminated and the end point made more distinct.

9435. **KUTTNER, THEODORE, and LOUIS LICHTENSTEIN. Micro-colorimetric studies. 2. Estimation of phosphorus: Molybdic acid-stannous chloride reagent.** *Jour. Biol. Chem.* 86(2): 671-676. 1930.—The method, which is described in detail, is specific for inorganic P in solutions containing between 0.25 and 1.0 mgm. P per 100cc. From 0.01 to 0.03% of $SnCl_2$ reagent is optimum for color production. The color production does not require heat, but below room temp. the time required for color production increases as the temp. falls.—*D. J. Healy.*

9436. **LeVESCONTE, AMY, J. H. BUCHANAN, and MAX LEVINE. The biological estimation of glucose. II. The relation between glucose concentration and the pH change in media.** *Iowa State Coll. Jour. Sci.* 4(4): 451-557. 1930.—A method for determining sugar in concentrations between .01 and .04% by the rate of pH changes is described. The accuracy of the method is stated to be from .001 to .025%. Glucose and fructose produce acid at the same rate under the conditions of the determinations. A biological method of determining sugars seems feasible.—*D. J. Healy.*

9437. **LOONEY, JOSEPH M. The determination of blood urea nitrogen by direct Nesslerization.** *Jour. Biol. Chem.* 88(1): 189-195. 1930.—The author uses a concentrated urease solution and "stabilizes" the complex ammonium-mercuric iodide by means of gum ghatti.—*M. R. Freeland.*

A shaking instrument is described.—*W. J. Meek.*

9449. **KING, JOSEPH T. An "Activated" Extract for Coagulating Heparin-Plasma.** *Arch. Exp. Zellforsch. Bes. Gewebezücht (Explantation)* 10(4): 467-473. 1931.—Addition of a few drops of heparin-plasma to tissue

extract gave an "activated" extract which coagulated with heparin-plasma more rapidly than untreated extract. With such extracts the use of higher concentrations of heparin is possible, thus avoiding loss of materials and the uncertainty which has attended the clotting of plasmas containing high concentrations of anticoagulant with weak tissue extracts.

9450. **KROETZ, CHRISTIAN. Messung des Kreislaufminutenvolumens mit einem neuen Kohlensäureverfahren.** *Zentralbl. Inn. Med.* 51(15): 275-286. 1930.—A modification of the original method of Brocklehurst, Haggard, and Henderson is given; the arterial CO_2 and the venous alveolar CO_2 tension are determined simultaneously, obviating errors in the varying respiratory middle position.

9451. **MARKOWITZ, J., and HIRAM E. ESSEX. Observations on the preparations and activities of a visceral organism.** *Amer. Jour. Physiol.* 92(1): 205-213. 1930.—By a simplified modification of Carrel's method it is possible to prepare a visceral organism which includes the heart and lungs, gastro-intestinal tract, spleen, pancreas, suprarenal glands, liver, kidneys, ureters, and bladder, which under favorable conditions may survive for several hrs. Artificial respiration, an incubator to maintain a normal temp. and occasional transfusions are necessary. Arterial transfusions are particularly useful in keeping up the coronary blood flow. The heart rate in the visceral organism is about 120 to 200 a minute; the blood pressure may be as high as 90 mm. of Hg. Peristalsis in the gastro-intestinal tract is intensely active, the upper segments particularly demonstrating marked rhythmic contractions. Food is absorbed from the intestine and chyle appears in the lacteals. The kidneys secrete urine and polyuria often depletes the volume of blood. The liver and pancreas retain their normal appearance throughout. The life of the organism is limited by the appearance of edema in the abdominal viscera and due to this fluid loss, repeated transfusions are necessary. The cause of death is chiefly cardiac. There is often pronounced autodigestion of the gastro-intestinal tract.—*A. M. Snell.*

9452. **SANO, MACHTELD, and LAWRENCE W. SMITH. A simplified method for quantitative tissue culture in vitro.** *Proc. Soc. Exp. Biol. & Med.* 28(3): 282-284. 1930.—A combination of technics and adaptation of principles used in cover slip method of Maximov, as well as apparatus of Carrel and Borel flash. The authors' device consists of petri dish, sheets of mica and a glass ring.—*S. E. Pond.*

9453. **SERENI, ENRICO. Un preparato per la circolazione crociata negli octopodi.** *Boll. Soc. Italiana Biol. Sperim.* 3(10): 1304-1309. 1928.—To study certain phenomena of blood correlation, 2 methods have been developed of obtaining preparations with cross circulation among Cephalopods. With the 1st there is only a brief survival, but with the 2nd there is a survival of 10-12 hrs. In the 2 animals united, many functions (as coloration) tend to become uniform rapidly, showing that these functions are regulated at least in part by blood factors. When the animals united are of different spp. the survival is shortest. This shows that survival is limited by biological factors.—*S. Sereni (transl. by S. A. Watson).*

9454. **SOKOLOWSKI, A., et M. KUBICZEK. Recherches cliniques et histologiques sur la valeur de la méthods de compression de Kylin dans la mesure de la pression sanguine dans les capillaires.** *Ann. Méd.* 29(4): 410-422. 3 fig. 1931.—Kylin's method (compressing the finger immediately behind the ungual fold) really measures the pressure in the afferent arterioles of the subcutaneous tissue, especially the arteriole of Spalteholz. The values so obtained are therefore higher than those of pressure in the capillaries and precapillaries.

9455. **BARKAN, GEORG. Zur Frage des Blutfarbstoffzerfalls durch verdünnte Säuren.** *Biochem. Zeitschr.* 224(1/3): 53-62. 1930.—Supplementing earlier investigations, the colorimetric behavior of acid hematin solutions from HbO_2, HbCO and from blood has been studied. Contrary to the conclusion of Lintzel and Radeff, dilute acid does not split Fe from oxyhemoglobin. The results are in harmony with the earlier conclusion of Barkan as to the nature of the loosely combined Fe of blood.—*Author's summary (transl. by D. B. Dill).*

9456. **BENCSIK, F., A. GÁSPÁR, F. VERZÁR, und A. ZIH. Weitere Untersuchungen über die Wirkung von Bilirubin auf die Zahl der roten Blutkörperchen.** *Biochem. Zeitschr.* 225(4/6): 278-285. 3 fig. 1930.—In 5 mice it was possible as a rule to produce erythropoiesis through single doses of 0.01 to 0.02 mgm. of bilirubin; larger doses (0.2 mgm.) gave erythropenia. The same was possible on 8 rats: 1-2 mgm. resulted in erythropoiesis, above 2 mgm. in erythropenia. By means of daily feedings of very small doses of bilirubin (0.005 mgm. in 1 mouse, 0.05 to 0.1 mgm. in 6 rats) one can raise the number of red blood cells appreciably for a month. If the dose is discontinued there is a return to the original value. When the number of red cells is altered by bilirubin the refractive index of the blood serum is unchanged. Since the bilirubin effect is proven on the rabbit and man as on the mouse and rat and since it is so outstanding that small doses bring about erythropoiesis and large doses the reverse, since it is possible to produce a month long increase of the red blood cell number and since the serum concentration is not altered thereby, it follows that the bilirubin itself has a powerful effect on red blood cell formation. This supports our hypothesis that the bilirubin continually formed during blood destruction is an essential regulator of red blood cell number.—*Authors' summary (transl. by P. C. Foster).*

9457. **BERKHOUT, P. J. TEDING van. Determination of rest-nitrogen in the blood of inhabitants of the tropics.** *Mededeel. Dienst Volksgezondheid Nederlandsch-Indie* 19(1): 30-43. 1 pl., 1 fig. 1930.—Altogether the investigation of 12 healthy male and 2 healthy female Europeans (Nos. 1 and 3) yielded 31 colorimetric and as many titrimetric figures, and that of 21 healthy natives 43 and 40 figures by the two methods respectively. The mean results obtained with 19 natives by both tests, carried out at the same time and in duplicate, amounted to: colorimetric 32.0 mgm. % (maximum, 37.7; minimum, 28.0); titrimetric 31.8 mgm. % (maximum, 36.9; minimum, 28.2) with a standard deviation of ± 2.26 and a probable error of ± 0.35; and with 14 Europeans: colorimetric 31.46 mgm. % (maximum, 36.5; minimum, 25.3); titrimetric 30.96 mgm. % (maximum, 36.5;

minimum, 25.7) with a standard deviation of ±3.04 and a probable error of ±0.55. Consequently both methods gave well-nigh identical results for Europeans as well as for natives. These results agree with those obtained by the author in 1924 with Europeans and natives and in 1927 with natives only, and do not point to a difference between the percentages rest-N of Europeans and natives. The same holds for the percentage of uric acid, which was read simultaneously with that of the rest-N of a certain number of the test-individuals, Benedict's method being employed. Results of the same magnitude were obtained as those found in 1924 for 10 Europeans and natives.—*Author's summary.*

9458. BEZNÁK, A. VON. Die Wirkung der Parathyreoidectomie auf die Senkungsgeschwindigkeit der rotem Blutkörperchen. *Biochem. Zeitschr.* 225 (4/6): 312-317. 2 fig. 1930.—Studies were made on 6 dogs and 3 rabbits. If the parathyroids are removed from rabbits and dogs the sedimentation rate of the red blood cells is increased. From these observations it may be assumed that there is a diminution in the content of the blood of the negatively charged Ca-complex.—*Author's summary (transl. by P. C. Foster).*

9459. BINET, LÉON. La Rate. Organe réservoir. 116p. 1 col. pl., 12 fig. Masson et Cie: Paris, 1930. Pr. 20 fr.—Finding in 1926 that the transient polycythemia of asphyxia was absent in splenectomized animals (Barcroft's reservoir function), the author planned a number of studies, which are here reported as follows: 1, the hematological effects of acute asphyxia in the normal and splenectomized dog, the splenic origin of asphyxic polycythemia, etc.; 2, the contractions of the spleen during exercise and the results produced; 3, the contraction of the spleen following hemorrhage and the paradoxical polycythemia following a small hemorrhage; 4, the splenic reservoir during digestion, and the excitomotor effect of secretion on the spleen; 5, splenic contraction following emotion and the stimulation of sensory nerves; 6, the blood of the splenic vein and the capacity of the splenic reservoir; 7, the histophysiology of splenic contraction; 8, the humoral and nervous mechanisms of splenic contraction. The results confirm and in some cases amplify Barcroft's elucidation of this one of several functions of the spleen.—*E. B. Krumbhaar.*

9460. BLANKENSTEIN, ALFRED, und ANTON FISCHER. Untersuchungen über die chemische Konstitution der Serum- und Gewebseiweisskörper. II. *Biochem. Zeitschr.* 224 (1/3): 211-222. 1930.—On the basis of further analysis of serum protein (human), it is possible to separate both pseudoglobulin and acid-albumin into 2 fractions which differ definitely in their content of amino acids. The separation of pseudoglobulin is accomplished by means of precipitation in a ⅓ saturated $(NH_4)_2SO_4$ solution, with the acetate buffer solution present in the proportions 10:3. The acid-albumin is obtained by precipitation in the acid-globulin filtrate with a saturated $(NH_4)_2SO_4$ solution in the proportion 10:2; or in case no precipitate results, in the proportion 10:7.5. Researches on tissue protein, with the method described, allow the proteins of the different organs to be distinguished; wherefore it is not probable that serum and tissue protein are identical. Studies on the separated protein portions of the skeletal- and heart-muscles show that the muscle protein in all probability consists of 3 chemically different fractions. None of these fractions is identical with any protein of blood serum.—*L. S. Godfrey.*

9461. BONOMO, V. Ricerche sperimentali sugli effeti della narcosi sulla riserva alcalina e sul pH del sangue. [Experimental researches on effect of narcosis on alkaline reserve and pH of blood.] *Arch. ed Atti Soc. Ital. Chir.* [*Roma*] 34: lxi. 1927 [1928].

9462. BORGHI, BRUNO. Ricerche sulla riserva alcalina nei conigli trattati con iniezioni di quantità massime di glucosio. [Researches on alkaline reserve in rabbits treated with maximum doses of glucose.] *Biochem. e Ter. Sperim.* 15 (3): 90-107. 1928.—The figures for the alkaline reserve in rabbits injected with massive doses of concentrated solutions of glucose present some variations, which though slight, deserve comment. With a single injection of glucose the diminution of the alkaline reserve is closely related to the acid producing effect of a sudden entrance of glucose into the circulation with disturbance of the intermediate metabolism and formation of fixed organic acids. Small oscillations of the alkaline reserve were observed in the rabbits during the day. The author always found a diminution, small but definite, after a glucose injection. This diminution becomes attenuated after repeated injections as though the organism adapts itself to the disturbance in the acid base equilibrium. A constant reduction of the alkaline reserve does not take place. In rabbits 1 and 3 of Series 1 there was even an increase which may not be due to the treatment but as Hawkins points out occurs normally in rabbits and guinea pigs (variations of pH from 7.26 to 7.58). The H-OH iso-ionic balance is evidently less perfect in these animals than in man and variations are difficult to appraise. No permanent compensatory acidosis can be produced in rabbits by massive injections of glucose, nor can the loss of glycogen in the organism be explained by this mechanism.—*Author's summary (transl. by P. Hillkowitz).*

9463. BRECHER, LEONORE. Die anorganischen Bestandteile des Schmetterlingspuppenblutes (Sphynx pinastri, Pieris brassicae). Veranderungen im Gehalt an anorganischen Bestandteilen bei der Verpuppen. *Biochem. Zeitschr.* 211 (1/3): 40-64. 1929.—Determinations of inorganic components of pupal blood of *Sphinx pinastri* gave as averages: K 137.8 mgm., Ca 33 mgm., Mg 56 mgm., Cl 57.5 mgm., P 66 mgm. %; Na in too small amounts to measure by human blood methods. No differences between ♂ and ♀ in content of K, Ca, Mg and inorganic P; Cl being in doubt. An excess of bases (0.050 gram-equivalents per liter, i.e., 0.096 vs. 0.046) presumably combined with organic acids. In comparison with human blood serum, there is very little Na but much more K, Ca, P, and especially Mg, much less Cl. Determinations in *Pieris brassicae* before, during, and after pupation gave an increase in K and decrease in Ca in the successive stages: (1) mature larva still feeding, (2) wandering prepupa with red intestinal content, (3) suspended prepupa, (4) pupa. Mg in the feeding larva much exceeds that in the prepupa and pupa; Cl in the larva is somewhat higher than in the pupal stages, which show no differences inter se. The total P (including organic) in the first prepupal stage is less than in the feeding larva, but increases in the suspended prepupa and is much higher in the pupa than in the feeding larva.—*Author's abst. (transl. by J. H. Gerould).*

9464. BUCKNER, G. DAVIS, J. HOLMES MARTIN, and W. M. INSKO, Jr. The blood calcium of laying hens varied by the calcium intake. *Amer. Jour. Physiol.* 94 (3): 692-695. 1930.—A $CaCO_3$ supplement to the grain-skim milk ration was administered to 9 laying hens, 9 others of the same breed, age and laying conditions receiving no such supplement. In the lot receiving $CaCO_3$ the average egg production, average weight of dry shell and average weight of egg contents increased, the average Ca content of the blood serum was not diminished and the physical condition of the hens remained good. In the hens receiving no supplementary $CaCO_3$ the Ca of the serum diminished; so did egg production and weight of egg and shell, while physical condition deteriorated. In previous experiments no such decrease in Ca of blood serum occurred in cocks or non-laying hens deprived of a $CaCO_3$ supplement.

9465. CANTO, A. Variaciones de las proteínas del plasma por la hepatectomía. [Variations in plasma proteins after hepatectomy.] *Rev. Soc. Argentina Biol.* 6 (3): 188-197. 1930.—Ten dogs were hepatectomized (Markowitz and Soskin's technique in 7 and Kepinow and Petit-Dutaillis in 3). They survived from 2 h. 50 min. to 4 h. 30 min. Blood always clotted but usually with delay after hepatectomy. Total plasma protein diminished 28%, albumin 35%, fibrinogen 36%, glo-

bulins 17%; the ratio albumin: globulin diminished always, from 1.28 to 1.03 (average figures in all cases). Non protein N increased slightly in most cases, but diminished in others. Controls anesthetized, abdomen opened and liver massaged gave no significant variations.—*J. T. Lewis.*

9466. CHARIPPER, HARRY A. Hemolysis of the erythrocytes of Amphibia. *Amer. Jour. Physiol.* 94(2): 278-284. 1 pl. 1930.—Time-dilution curves are given for the hemolytic action of saponin, sodium taurocholate and sodium oleate on the erythrocytes of 3 different species of Amphibia: *Siren lacertina, Necturus maculosus* and *Rana catesbeiana.* Resistance values for the red cells of each of the animals are given for the 3 lysins. All 3 lysins produce hemolysis in each animal. Sodium oleate also causes karyolysis. Microscopic observation of the nucleated red cell in the presence of the lysins, for all 3 forms studied, show changes similar to those reported for the nucleated red cell of chicken blood and the non-nucleated red blood cell of mammals.—*Author's conclusions.*

9467. CIACCIO, C. Sui fattori determinati e sulla natura della reazione leucocitaria alimentare. [Determining factors and nature of the alimentary leucocytic reaction.] *Arch. Sci. Biol.* [*Napoli*] 12: 211-230. 1928.—Tschishikow holds that following the giving of protein beside a primary leucocyte increase connected with gastric secretion, there may be a second and later one in connection with the absorption of the products of protein digestion. The fundamental and constant phenomenon of the alimentary leucocytic reaction is in intimate connection with the activity of hemopoietic tissues, the periodic function of which, like others occurring during the period of digestion, is determined essentially by the passage of gastric HCl into the intestine and is incidental to and probably follows the absorption of protein during a later phase. There are 3 possibilities to be considered relative to the intermediary mechanism: the influence of the liver, the pancreas and the reticulo-endothelial system. With regard to the latter and particularly the hemopoietic tissues, it is demonstrable: 1) that the cytolytic activity is to be explained extrinsically during the digestive period and is in response to the same factors that determine the functional state of the hemopoietic tissues; 2) that extracellular cytolysin follows that of intracellular origin; 3) that a cytogenetic activity is coincidental with cytolytic processes. Such results suggest that the r.e.s. intervenes in some way explanatory of the digestive, leucocytic reaction and that there may be an intimate relation between cytolytic and cytogenetic phenomena. Accordingly the following possibility is advanced: Cells metabolically intermediate, or r.e. cells, elaborate ferments that at first produce an intracellular leucolysin and then set free an extracellular one. Both act especially on elements of advanced maturity. The same ferments or the products of cytolysin act as stimuli on the young elements which proliferate, mature and enter the circulation.—*Author's summary* (*transl. by J. G. Edwards*).

9468. COLSON. Régénération du sang après la saignée chez le Boeuf. *Rec. Méd. Vét. École d'Alfort* 106 (8): 476-481. 1930.—Since young and adult animals show hematological differences, comparisons should be made with animals of about the same age. An animal bled once, reëstablishes both the red and white counts within 4-6 days; a marked hyperleucocytosis always occurs in the first 6-24 hrs. A young healthy animal endures a large number of bleedings without change in amount of red or white cells, excepting the transient variations following each bleeding. The numbers are normal within a week after the last withdrawal. An old animal in average condition regenerates its leucocytes in 12-15 days but its erythrocytes require 2 mos. or longer. Hence these animals require prolonged rest between different series of bleedings, and verification of the value of their serums is indicated.—*Author's conclusions* (*transl. by W. A. Peabody*).

9469. CONDORELLI, LUIGI. Das elektrolytische Gleichgewicht des Blutes. Einfluss des zentralen Nervensystems. *Zeitschr. Klin. Med.* 107(1/2): 1-33. 27 fig. 1928.—Previous work by C. has shown a very rapid mechanism for regulating the electrolytes in the blood when salts are injected. In the present work lesions were made in various regions of the brain of dogs under morphine-ether anesthesia. A considerable disturbance of the electrolyte equilibrium occurred in 5 out of 6 animals in which the lesion was in the thalamus. The most usual changes in these animals were decreased Ca, and increased K and inorganic P, but they depended a great deal on the exact placing and extent of the lesion. The maximum change occurred in 24 hrs., and the concentration returned to normal only after several days.—*R. S. Anderson.*

9470. COUPIN, FERNANDE. Les formations choroïdiennes des poissons et la question de l'origine du liquide céphalo-rachidien. *Schweizer Arch. Neurol. u. Psych.* 26(2): 227-229. 1930.—From experiments made with fishes no definite conclusion can be drawn. The results obtained by Grynfelt and Euzière and by Pettit and Girard are not sustained. One can only affirm that the plexus plays a rôle in the movement of the ventricular fluid. On taking particular precautions for fixation, one sees that, everywhere, the choroid cells have a brush-like border of very large and numerous cilia; on examination of the plexus in physiological saline, or, better, in the serum of an animal, one can follow the very delicate and regular movements of the cilia establishing some currents in the ventricular fluid the rôle of which is unknown to us. One understands, moreover, that there can exist in pathological conditions a change in the choroid cells, as has been shown by M. von Monakow and his students, for many cases of dementia (atrophy, hypoplasia, microphasia). The knowledge of the rôle of the choroid plexus in the movements of the ventricular fluid, does not, however, exclude other functions. In the actual state of our knowledge we are not permitted to consider the c.s.f. as a product of the choroid plexus; the c.s.f. must rather be a dialysate comparable to the other fluids of the organism such as the pericardial fluid, the aqueous humor, synovial fluid, pleural, amniotic fluid, etc., of which the mechanism of formation is still to be explained.—*From author's article* (*transl. by M. R. Freeland*).

Rous sarcoma cells contain a heat stable substance which can activate the fibrin liquefying factor of plasma. This substance is released in the culture medium when the cells die. Fibrin is not split in the liquefying process.—*W. N. Berg.*

9472. DIERYCK, JOSEPH. Recherches expérimentales sur les épreuves fonctionnelles du système réticulo-endothélial. L'épreuve au Rouge-Congo de Adler et Reimann. *Rev. Belge Sci. Med.* 1(8): 685-752. 8 fig. 1929.—In 174 experiments on rabbits great individual differences appear in the rapidity with which Congo-red injected into the blood disappears from circulation, but the rate of elimination remains approximately the same for the individual; the results are due in the main to the pigment-fixing activity of the reticulo-endothelial cells. Gestation produces, first a slight delay, then a marked increase (disappearing after delivery) in the elimination of Congo-red. Splenectomy is followed by acceleration of elimination which may last for months, but which tends generally to return to normal. Injections of India ink, collargol, iron saccharate, and caseosan produce a stimulating or blocking effect according to the dose injected and the interval between injections. Thyroxine stimulates, epinephrine, ephetonin, pilocarpine, acetylcholine, ergotamine, atropine and histamine retard the disappearance of Congo-red. Ligation of the bile-duct and extirpation of the greater part of the liver

cause considerable retention of the dye. Bengal rose is eliminated by the liver much more rapidly than is Congo-red; it is more readily affected than Congo-red by an India ink blockage. Its elimination may be accelerated by injection of caseosan and thyroxine, or temporarily prevented by splenectomy. While Bengal rose is an excellent test of hepatic permeability, it may be considerably influenced by temporary modifications in the permeability of Kupffer's cells. In the chromagogic function of the liver there are 2 distinct mechanisms: (1) a mechanism of filtration and concentration, which operates only for crystalloid dyes; (2) a Kupfferian mechanism, of segregation, which places electro-negative colloids in temporary storage.—*From author's abstract (transl.)*.

9473. **DUKES, H. H., and L. H. SCHWARTE. The hemoglobin content of the blood of fowls.** *Amer. Jour. Physiol.* 96(1): 89-93. 1931.—Study of the Hb content of the blood of 23 chickens and a number of wild pheasants, ducks, geese, brants, swans, peafowls, and turkeys by the Newcomer method (with correction applying to the "Improved Newcomer Model" hemoglobinometer for the turbidity of acid hematin solutions prepared from bird blood) indicates that the Hb content of the blood of wild fowls is higher than that of the blood of chickens.

9474. **EATON, PAUL, and F. L. DAMREN. A method for determining the life duration of the erythrocyte: II. The rate of red cell production after hemorrhage.** *Southern Med. Jour.* 23(5): 395-402. 1930.—Reticulocyte counts were made on more than 100 blood smears made over a period of 30 days from a rabbit which had lost 25% of its blood: 56 of these smears were made at intervals of 1½ hrs. over the 1st 100 hrs. of the experiment. The preoperative level of reticulocytes was established by averaging 19 counts made over a period of 30 odd hrs. 2 days before bleeding. A series of spontaneous anemias was indicated by high reticulocyte counts on the 10th, 18th, and 26th days after bleeding; following the highest count of 8% on the 2nd day. The interpeak values were comparable with the preoperative level. The most important finding seems to be the fact that the ratio between 2 readily distinguishable types of reticulocytes furnishes the most delicate and precise measure of activity of the erythropoietic system. Its indications are the more important and valuable in that they relate to what has been happening in the red cell producing system in the 3 hrs. immediately preceding the test.—*Authors' summary.*

9475. **EISLER, M., und F. FRIZA. Über den Verlauf der Hämolyse an narkotisierten Erythrocyten.** *Zeitschr. Ges. Exp. Med.* 74(5/6): 625-635. 1930.—Mixtures of isotonic solutions of ethyl-, propyl-, butyl-, and amyl-alcohols are used in such concentrations with rabbit or sheep blood that no marked changes occur after long observation; after standing 10 min. at 36° C. in 0.45-0.55% NaCl solution, these tests reveal delayed hemolysis. The various alcohols act for the most part alike. If the alcohol is separated after 10 min. by centrifuging lysis appears at practically the same time as in the controls. Urethane acts in a similar manner. The same treatment of the blood with ethyl and propyl alcohol likewise effects a delay in hemolysis caused by "Kadikojtoxin." Butyl alcohol delays hemolysis with rabbit blood but not with sheep blood. Amyl alcohol is ineffective with rabbit blood and with sheep blood promotes lysis. Four varieties of urethane studied also inhibited the toxin hemolysis of rabbit or sheep blood, nevertheless the higher members of the series are somewhat less effective than the lower. This inhibition is eliminated by removal of the urethane. Sometimes lysis occurs earlier under these circumstances than in the controls. —*G. D. Smith.*

9476. **ETTISCH, G., und W. EWIG. Zur Elektrodialyse des Serums.** *Biochem. Zeitschr.* 195(1/3): 175-188. 2 fig. 1928.—In the work presented, there are (1) the conditions outlined by which an ideal, minimal fractioning of serum globulin through electrodialysis must take place. These conditions hold good in: (a) conversion of undiluted serum; (b) avoidance of far-reaching change in reaction; (c) maintenance within the physiologic limits of temperature (under 36°); (d) more rapid fractioning; (e) the most thorough precipitation of albumin. (2) It is shown in how far the methods presented do not satisfy these strict conditions. (3) An albumin-collodion membrane is described which—as an anodal membrane—together with a parchment membrane presents a combination by means of which it is possible to satisfy the conditions stated. (4) It is shown that the above mentioned membrane cannot be replaced by a simple collodion membrane.—*Authors' summary (transl. by M. M. Wintrobe)*.

9478. **FORSSMAN, J., TH. WADSTEIN, und G. FISCHER. Der Einfluss verschiedener Salzkonzentrationen auf die Hämagglutination.** *Lunds Univ. Årsskr. Sect. 2. Med. Mat. Naturvetensk.* 26(paper 4): 1-7. 1930.—The NaCl concentration causing the most marked agglutination is 3% for sheep blood, 5 for ox blood and 1 for pig blood. In the 2 former species agglutination results up to 10 or even 15% salt concentration. There are 2 agglutinative types of human blood, one of which is characteristic for the A-group-anti A-serum. Venesection in the sheep often increases the agglutinative stability of the corpuscles. On the whole alkali and alkaline earth salts in isotonic concentrations have the same effects as NaCl. The results indicate that the potential difference between blood corpuscles and the fluid is not decisive in agglutination by specific anti-sera but that other influences turn the scale.—*Authors' summary (transl. by D. B. Dill)*.

9479. **FREMONT-SMITH, FRANK, TRACY J. PUTNAM, and STANLEY COBB (with the technical assistance of MARY E. DAILEY, MARGARET A. CARROLL, and CAROLINE STEPHENSON). Forced drainage of the central nervous system. Its effect on the blood and on the cerebrospinal fluid.** *Arch. Neurol. & Psychiat.* 23(2): 219-227. 1930.—A modification of Kubie's method of forced drainage of the central nervous system and the results of its use in 16 patients (multiple sclerosis and others) are reported. Pituitary extract is injected so as to delay diuresis which would otherwise result from the forced fluids given by mouth. The consequent dilution of the blood caused a dilution of the cerebrospinal fluid as shown by an estimation of the freezing point and of the Cl and Na contents. There was also a change in the protein and cell count.—*W. Malamud.*

9480. **GOODALL, EDWIN. Blood-cholesterol during the menstrual and epileptic cycles.** *Lancet* 1(5504): 384-386. 1929.—The experiments were made to test the statement of Robinson, Russell Brain, and Kay [*Lancet* 2: 325. 1927] that the blood-cholesterol is markedly decreased at or about the menstrual period. The patients (12 mentally disordered women, aged between 22 and 47; 10 quiet, deluded patients of the chronic class, 2 quiet mental defectives) were placed on a diet of, as closely as possible, 17 calories per lb. of body-weight, composed of bread, butter, milk, meat and potatoes. Each was kept in bed for not less than 3 days before the withdrawal of blood. The 12 patients were examined for cholesterol in 2 phases of the menstrual cycle—intermenstrual (all patients in bed and on the diet for 3 days before the 1st estimation), and intra-menstrual (same conditions observed for 3-10 days before the 1st estimation). Two series of estimations were made (72 in each

series) and the mean results of the 2 were in most cases in agreement to within about 10% (in ½ the cases to within 5%): the agreement was somewhat closer in the inter-menstrual than in the intra-menstrual results; the amount of cholesterol present in the blood is the same in the inter-menstrual as in the intra-menstrual period. The author also examined the whole blood of 6 cases (3 ♂ and 3 ♀) of long-standing epilepsy, with dementia to a greater or lesser extent. In each case 3 estimations were made in the inter-paroxysmal and 3 in the pre-paroxysmal phase (36 in all). In 5 out of the 6 cases the blood-cholesterol in the inter-paroxysmal phase was fairly constant over the 3 days on which estimations were made; in the 6th case one of the values was considerably higher than the other 2. In 4 out of 6 cases the blood-cholesterol in the pre-paroxysmal phase was fairly constant over the 3 days; in the 2 remaining cases the variation was more marked. The mean value for the blood-cholesterol in the pre-paroxysmal phases is not markedly different from that in the inter-paroxysmal phases. The variations from the mean tend to be greater in the former.

9481. **GOSSMANN, H. P. Zur Morphologie des Lymphknotens in ihrer Beziehung zur Funktion. Untersuchungen an der Leberpfort- und Gekröselympfknoten.** *Virchow's Arch. Pathol. Anat. u. Physiol.* 272(2): 383-399. 1929.—Lipid substance was found in ⅔ of all sectioned material from mesenteric lymph nodes of 150 cases and mesenteric and portal nodes of 100 cases. Mesenteric nodes were more favorable. Staining pictures indicative of absorption were found in the reticulo-endothelial cells and the reticulum of the parenchyma, even in the secondary nodules, but not in the parenchyma itself. With a rapid inflow of fat, the sinuses showed the greatest absorption. With a slower inflow, it showed in the sinus first and in the reticulum later. The fat is completely digested, making a contrast with the indigestible pigment in these cells.—*From abst. by P. Caffier (transl. by C. M. Goss).*

Physiol.* 59(5/6): 226-230. 1930.—The pH values were determined by Mislowitzer's method using a gold electrode. Blood from the left heart of rabbits became more acid when there was a marked vagus effect and was least effected in hypodynamic hearts.—*Authors' summary (transl. by D. B. Dill).*

9483. **GUSSAROW, I. I. Ca-Spiegel in Blutserum bei experimentellen Knochenfrakturen.** *Arch. Klin. Chir.* 155 (1): 39-50. 9 fig. 1929.—In cases of bone injury and subsequent callus formations, there is a displacement of the otherwise stable Ca equilibrium which is shown by its increase in blood serum. The increase of the Ca content of serum beginning with the separation of Ca in the osteoid callus continues until complete consolidation has occurred. There follows a gradual diminution in the Ca content. The original rise in Ca content appears to depend upon the hyperfunction of epithelial cells as a result of which a mobilization of Ca from the bone system takes place.—*J. M. Johlin.*

9484. **HAWKINS, W. B., K. SRIBHISHAJ, F. S. ROBSCHEIT-ROBBINS, and G. H. WHIPPLE. II. Bile pigment and hemoglobin interrelation in anemic dogs.** *Amer. Jour. Physiol.* 96(2): 463-476. 1931.—A severe experimental anemia due to bleeding may be combined with a renal-bile fistula and enable the investigators to follow simultaneously new Hb production and bile pigment output under carefully controlled conditions. Dogs can be kept in perfect physical condition with normal activity and uniform weight under these conditions provided care is taken to insure suitable diet intake. Under such conditions the base line control output of bile pigments per 24 hrs. is much less than during non-anemic periods. This bile pigment output does not fall as low in proportion as does the anemia level—for example, with an anemia level of ⅓ normal Hb, a bile pigment output level of ½ normal was observed. This pigment paradox reads about as follows—from the injected Hb comes a quantitative return of new Hb in red blood cells removed by bleeding. At the same time there is almost a quantitative return from the same Hb injection in the form of bile pigment. Whatever pigment is accepted as the end product of the introduced Hb, there remains the necessity of explaining the other pigment formation. The authors suggest that from the injected Hb is split off the pyrrole nucleus to form bilirubin and from the globin fraction or parts of it may come much of the new Hb which appears in the circulating red cells. If this is true it appears that the body can synthesize the pyrrole nucleus in considerable amounts in an emergency due to anemia.—*Authors' summary.*

9485. **HENSEL, SIEGFRIED. Über den Indikangehalt im Serum am Ende der normalen Gravidität bei Mutter und Kind.** *Zeitschr. Geburtsh. u. Gynäkol.* 98(2): 276-290. 1930.—The indican content of the serum at the end of normal pregnancy is not higher than about 0.8 mgm. % (in 30 cases). The results with non-pregnant women of child-bearing age (10 cases), whose blood indican values reached about 1 mgm. %, do not indicate an increase in blood indican above the normal in pregnancy. There is no evidence for the existence of a "physiological hyperindicanemia of pregnancy." The blood of the fetus contains more indican than that of the mother. The level lies between about 0.3 and 1.5 mgm. %. Immediately after birth no indican is eliminated in the urine. It does not appear for several hours after birth. The indican of the fetus appears to be formed through the active intermediary metabolism of protein.—*Author's summary (transl. by B. S. Walker).*

9486. **HINTNER, H. Zur Frage des Einflusses von abnormen Resorptionsvorgängen im Genitalapparat auf den Blutlipasegehalt.** *Pflüger's Arch. Ges. Physiol.* 226 (2): 292-293. 1930.—The power of the blood of the rabbit to split tributyrin is not changed during normal pregnancy or after artificial destruction of the fetuses. —*M. H. Jacobs.*

9487. **HOCHREIN, M., J. MICHELSEN, und H. BECKER. Schlaf, Schlaflosigkeit und körperliche Arbeit in ihrem Einfluss auf den Blutchemismus.** *Pflüger's Arch. Ges. Physiol.* 226(2): 244-254. 1930.—The effect of sleep on the organism was studied in 2 normal subjects by comparing the effect of standardized exercise upon the blood chemistry in the morning before breakfast following a normal night's sleep and following a night during which the subject lay recumbent but without sleeping. In the morning while fasting, blood pressure and pulse rate were taken and a 60 cc. sample of venous blood drawn without stasis from the arm. The exercise consisted of a 5 min. run on a treadmill at 8 Km. per hr. following which within 2 min. blood pressure and pulse rate were again measured and a 2nd sample of blood taken. A 2nd 5 min. run at 11 Km. per hr. was then performed and immediately blood pressure, pulse rate and a 3rd sample of blood were taken. One such experiment after sleep and one after a sleepless night on each of the subjects was performed and is reported. The blood analyses included O capacity, CO_2 content of blood, plasma CO_2 at 40 mm., total base of plasma, Cl of blood and plasma, blood lactic acid, blood sugar, blood cell volume, and water content of blood and plasma. In all 4 experiments the definite changes following exercise consist of rise in blood pressure and pulse rate, fall in plasma bicarbonate, rise in blood lactic acid, slight increase in blood cell volume and slight fall in water content of blood and plasma and in blood sugar. The authors note a slight fall in O capacity and in plasma bases after the 1st run and a slight rise in both after the 2nd run but these changes are small. The consistent differences between the 2 experiments following sleep and the two following the sleepless night are limited to slightly lower cell volume, slightly higher water content of plasma and slightly higher blood and plasma Cl following the sleepless night

both before and after exercise and to greater lactic acid increase and greater fall in bicarbonate following exercise after the sleepless night.—*J. H. Austin.*

9488. **HOLZAPFEL, MAX. Untersuchungen über die wirksame Substanz bei dermographischen Erscheinungen.** *Zeitschr. Ges. Exp. Med.* 72(1/2): 269-281. 3 fig. 1930.—In Dermographia elevata, after mechanical stimulation of the skin a substance is produced which enters the circulation and is demonstrable in the serum by the fact that intracutaneous injection of this serum produces larger wheals with wider hyperemic borders than normal serum. Comparison of the action of this substance with the action of histamine makes it improbable that the 2 are identical.

9489. **HORWITZ, S. Acidose und Mikrocytose.** *Zeitschr. Klin. Med.* 113(3/4): 395-403. 1930.—The designation "macro- and microcytosis" refers only to erythrocyte diameters, not to their volumes. Increase of erythrocyte vol. with change from disk shape to globe shape, thus shortens the diam. In experimental acidosis, addition of four 10 cc. doses of dilute HCl produces microcytosis, i.e., erythrocytes with large vols. and smaller diams. Similarly microcytosis was produced by administration of other mineral acids equivalent to 135 cc. of normal solution per day.—*S. Horwitz (transl. by W. A. Peabody).*

9490. **JACOBS, M. H. Osmotic properties of the erythrocyte. I. Introduction. A simple method for studying the rate of hemolysis.** *Biol. Bull.* [*Woods Hole*] 58 (1): 104-122. 1 fig. 1930.—A simple method is described by which it is possible to measure with accuracy the rate of hemolysis where the time involved exceeds approximately 1 sec. If the duration is 10 sec. or more, a complete graphic record of the entire process up to an apparent degree of hemolysis of between 80 and 90% may be obtained. The method may also be used for the accurate determination of the relative numbers of erythrocytes in different suspensions and assuming a satisfactory definition for the expression "percentage of hemolysis," for the rapid estimation of the latter, within the range most useful for experimental purposes, with an error of no more than 1 or 2%.—*M. H. Jacobs.*

9491. **KAFKA, V., und K. SAMSON. Die Eiweissrelation des Liquor cerebrospinalis. IV. Die Beziehungen der Ergebnisse der Eiweissrelation zu den übrigen Liquorbefunden.** *Zeitschr. Ges. Neurol. u. Psychiatr.* 119(1): 153-162. 1929.—The upper limit of cells in the cerebrospinal fluid does not exceed 8/3 in a cu. mm. Fluids presenting 8/3 to 15/3 cells in a cu. mm. are to be classed as abnormal. The Wassermann reaction was always coincident with changes in the albumin relation. —*S. Katzenelbogen.*

9492. **KAISER, OTTO. Über den Einfluss temporärer Einschränkung des blutbereitenden Gewebes durch Gefässklemmung.** *Zeitschr. Ges. Exp. Med.* 72(1/2): 211-227. 5 fig. 1930.—The problem was whether a longer or shorter exclusion of a part of the bone marrow from circulation would produce degenerative cell injuries the products of which would affect blood production. It was studied in 5 guinea-pigs by repeatedly occluding with a clamp, for periods varying from ½ hr. to 5 hrs., daily in some and at longer intervals in others, the right femoral artery in its crural segment. Brief occlusion produced transitory lymphocytosis, indicating not increased production but a disturbance of cellular equilibrium. A protracted occlusion produced, by the formation of products of destruction of myeloid cells, a neutrophil blood reaction, generally with increase of mononuclears, sometimes also of eosinophils. The erythrocytes showed no typical reaction. A transient lengthening of the precipitation time followed each occlusion. The results tend to support the theory of the productive and functional opposition between the lymphatic and the myeloid cell systems, and of a quantitative equilibrium of the cell products entering the blood.

9493. **KAULBBERSZ, GEORGES. L'influence de la fatigue dans les montagnes et dans la plaine sur l'échange de l'eau dans l'organisme.** *Jour. Physiol. et Pathol. Gén.* 26(4): 616-623. 1 fig. 1928.—In 3 men observed during exercise in the mountains, at the beginning of fatigue dilution of the blood occurred, with fall in Hb, erythrocyte count, proteins, and to a less extent of density and solids of the blood; then followed a rapid concentration, then a secondary dilution by a protein-containing liquid from the tissues, salts, Hb and erythrocytes being diminished. The temp. remained stationary during dilution of the blood, but rose during concentration. Hence Kaulbersz agrees with Barbour in regarding increase of fluid in the peripheral vessels of the body as a temp.-regulating function.

Physiol.* 19(4): 377-379. 1929.—A left-handed deviation of the Arneth count in rabbits is produced by various gonad extracts as well as by pituitrin, adrenalin, and insulin.—*W. P. Kennedy.*

9495. **KLINKE, K. Experimentelle Hämolysestudien. II.** *Biochem. Zeitschr.* 197(4/6): 381-403. 1 fig. 1928.—According to the author's observations, the hemolysin (amboceptor) is absorbed by the red corpuscles and by affecting the lipid complex brings about a loosening of the structure of the membrane in a way which makes possible the action of the lysin. This consists in an adsorption by the loosened membrane of the euglobulin fraction of the serum. Alterations in the colloid chemical properties of the euglobulin interfere with the actual lysin. This is the manner in which salt inactivation, the addition of homologous serum and of caffein exert their effects. The hemolysin may act independently, so that cells treated with inactivated, non-hemolytic serum will hemolyze on the subsequent addition of the euglobulin fraction of the hemolytic serum. A similar process is indicated in the case of the antitoxic effects of suitable sera.—*M. Bodansky.*

9496. **KOVÁCS, EDMUND [with the assistance of ST. LUDESCHER, und L. ZAJÁCZ]. Beiträge zur Kenntnis des leukozytären Blutbildes im Säuglingsalter.** *Jahrb. Kinderheilk.* 128(3/4): 244-257. 1930.—Studies of 25 normal, 10 prematurely born, 24 exudative infants and 10 with acute catarrhal affections of the air-passages.

9497. **KOZUKA, KISHIRO. Über die Lävulose des Bluts und der Lymphe.** *Tohoku Jour. Exp. Med.* 15 (3/4): 398-418. 1930.—Levulose is present in the blood of normal rabbits, pigs, and dogs, averaging 7.2, 4.6, and 7.2 mgm. % respectively. After administration by mouth the blood levulose increases over 100%, while the blood glucose simultaneously increases moderately. In levulosemia the portal blood is highest in levulose followed in order by the lymph from the thoracic duct, and the blood of the carotid, jugular, and femoral veins. The blood of the left ventricle usually contains more levulose than that of the right. Adrenaline cannot mobilize levulose; insulin decreases the blood levulose. The increase in the blood sugar after levulose administration is much less than after an equivalent amount of glucose. Feeding an animal with either sugar causes no great differences in glycogen formation in the liver, and in skeletal and heart muscle.—*K. Kozuka (transl. by M. H. Power).*

9498. **KRAUSE, A. C., and A. M. YUDKIN. The chemical composition of the normal aqueous humor of the dog.** *Jour. Biol. Chem.* 88(2): 471-477. 1930.—The refractive index of normal aqueous humor taken from the eye of the dog under cocaine anesthesia showed a range of values from 1.33478 to 1.33532. The NaCl varied from 540 to 676 mgm., the inorganic sulfate as S from 0.24 to 0.50 mgm., the inorganic phosphates as P_2O_5 from 0.83 to 1.5 mgm., the CO_2 from 58.4 to 62.5 volumes %, the total N from 27 to 55 mgm., the protein N from 5 to 26 mgm., the non-protein N from 12 to 40 mgm., the urea N from 11 to 15 mgm., the amino acid N from 8.2 to 10.3 mgm., and the creatinine from 1.0 to 1.9 mgm. per 100 cc. of aqueous humor. Amytal anesthesia produced no change in the concentration of the creatinine, glucose, NaCl, total N, protein N, non-protein N or

refractive index of the aqueous humor of the dog. Ether anesthesia caused no variation in the amount of creatinine, protein N, and non-protein N. The refractive index was slightly, and the glucose content was greatly increased. Local irritation of the eye by ether vapor resulted in an increase of refractive index and protein. The analysis of aqueous humor, spinal fluid, and whole venous blood of the dog under amytal anesthesia showed the concentration of the NaCl was lowest in amount in the spinal fluid and the non-protein N content was the greatest in the whole venous blood.—*Authors' summary.*

9499. KUGELMASS, I. NEWTON, and EMMA LOUISE SAMUEL. Dietary protein and blood-clotting function. *Amer. Jour. Dis. Children* 41(1): 48-52. 1931.—Experiments on 24 rats and 4 dogs, and clinical observations indicate that prolonged feeding of a diet containing high protein increases the coagulability of the blood, maintaining the clotting factors at a higher level. Injury of the tissues by surgical intervention induces an overproduction of blood fibrinogen and hence an increased coagulability of the blood. The introduction of heterologous protein into the vascular system increases the blood-clotting function transiently, with a rapid return to normal.

9500. LASCH, FRITZ. Über den Leukozytensturz nach intrakutaner Injektion im höheren Lebensalter, ein Beitrag sur Biologie der Haut. *Wien. Arch. Inn. Med.* 20(3): 343-350. 1930.—Lasch and others had previously shown that intracutaneous injection of various fluids (albumin, salt solution, etc.), produces in 40-60% of young subjects a temporary fall of the leukocytes in the peripheral blood, the neutrophil elements alone disappearing. In the present study, intracutaneous injection of 0.9% NaCl solution produced a fall in leukocytes in 13 out of 32 subjects aged 61-94 yrs., the positive reaction appearing up to the 90th yr. In 7 out of the 32 cases a leukocytosis (affecting chiefly the neutrophil elements) appeared instead of a leukopenia, a phenomenon not yet observed in younger patients.

9501. LEITNER, J. Die Wirkung der Röntgen- und Ultravioletttstrahlen auf die Blutsenkungsreaktion. *Fortschr. Geb. Röntgenstrahlen* 41(4): 743-747. 1930.—In 43 experiments in vitro, Leitner observed no clear effect on sedimentation rate or regularity in the marked disturbances of the blood corpuscles following either ultraviolet or x-ray irradiation.

9502. LINTZEL, W., und T. RADEFF. Über die Wirkung der Luftverdünnung auf Tiere. III. Wirkung von Luftverdünnungen verschiedenen Grades. *Pflüger's Arch. Ges. Physiol.* 226(2): 307-318. 3 fig. 1930.—White rats were kept for 3 weeks in ventilated chambers at reduced atmospheric pressure in 5 groups as follows: 8 at 760 mm., 7 at 590 mm. (2000 m.), 5 at 460 mm. (4000 m.), 11 at 358 mm. (6000 m.), and 9 at 280 mm. (8000 m.). Two in each of the last 2 groups were given extra Fe with their food. Body weight at the beginning and body weight minus contents of the gastro-intestinal tract at the end were recorded. At the end of the experiment the authors measured the hemoglobin content of the whole body, the erythrocyte count and hemoglobin concentration of blood from the tail, the Fe of the liver not due to hemoglobin as a measure of the reserve Fe and the weight of the heart. Mean values for the 5 groups taking the value of the first control group as 100 follow. Erythrocyte count: 100, 110, 128, 128, 134. Hemoglobin concentration in tail blood: 100, 111, 131, 136, 133. Total hemoglobin per kgm. final body weight: 100, 136, 173, 210, 229. Blood volume calculated from two preceding data: 100, 121, 132, 154, 172. Heart weight per kgm. final body weight: 100, 98, 103, 142, 151. The rise in erythrocytes and hemoglobin is rapid at the lower altitudes approaching a level above 4000 m., with almost constant color index. The increase in blood volume and total body hemoglobin is noted throughout the series. The increase in heart weight is observed only in the last 2 groups when increase in hemoglobin concentration and erythrocyte count had ceased and is interpreted as evidence of increased minute volume output as a compensating factor at these altitudes. The iron analyses showed depletion in the reserves in some animals of the last 2 groups but no correlation between this and the hemoglobin values leading to the view that lack of Fe is not the cause of the diminishing increment of erythrocyte count and hemoglobin concentration at higher altitudes. The delayed rise in heart weight as compared with hemoglobin concentration argues against the increase in heart weight being a consequence of increased viscosity of the blood. —*J. H. Austin.*

9503. LIU, SCHAU-KUANG, und R. KRÜGER. Über die Regulation der Wasserstoffionenkonzentration im Blute. VII. Beiträge zur Frage der respiratorischen Regulierung der Wasserstoffionenkonzentration im Blute. *Zeitschr. Ges. Exp. Med.* 61(5/6): 787-793. 1928.—Injection of small quantities of dilute acids or alkalies produces only a transitory change in pH. The normal reaction is restored in 1 or 2 min. because of the high buffer value of blood and change in rate of carbonic acid excretion. Within normal physiological limits acid formation is nearly parallel to acid excretion. It is concluded that the respiratory stimulus depends on the pH.—*Author's summary (transl. by D. B. Dill).*

9504. LIU, SCHAU-KUANG. Über die Regulation der Wasserstoffionenkonzentration im Blute. VIII. Studien über die Wirkung von Säure, Basen und anderen toxischen Stoffen auf das Säure-Basengleichgewicht des Blutes. *Zeitschr. Ges. Exp. Med.* 61(5/6): 794-807. 1928.—The theory that H-ion controls the respiratory center is elaborated. So long as acid or alkali injections do not harm the respiratory center, breathing regulates the blood reaction. But when poisoning of the respiratory centers occurs, breathing becomes weaker and death supervenes. The danger of acidosis arises from possible paralysis of the respiratory center.—*Author's summary (transl. by D. B. Dill).*

9505. LUCK, JAMES MURRAY, and LEONARDE KEELER. The blood chemistry of two species of rattlesnakes, Crotalus atrox and Crotalus oregonus. *Jour. Biol. Chem.* 82(3): 703-707. 1929.—Compared to mammals, the bloods of 2 spp. of rattlesnakes, *Crotalus atrox* and *Crotalus oregonus,* contain only traces of urea. Amino acids, inorganic phosphates and chlorides are present in greater, and reducing sugar and cholesterol in smaller quantities than in mammalian blood. The non-protein N, creatine, creatinine, and liquid P values are of the same magnitude in *Crotalus* and mammalian blood.—*H. C. Koser.*

Zeitschr.* 215(4/6): 286-292. 1929.—From serum filtrates the purine bodies are precipitated by sublimate at pH 5.6. Ammonia and creatinine are precipitated together by adding ¼ vol. of 50% sodium acetate to the resulting filtrate. They are then separated and determined singly. Amino acids and urea are precipitated from the 2nd filtrate by neutralization to phenolphthalein. The precipitate is dissolved in dilute acid, Hg removed with H_2S, and the amino acids determined colorimetrically or titrimetrically. Provision is also made for the estimation of creatine. The scheme of analysis is applicable to 2-5 cc. of serum, and 92-100% of the non-protein N is accounted for.—*M. H. Power.*

9508. LUSTIG, B. Zur Kenntnis der Unterfraktionen der Globuline und Albumine im Serum. *Biochem. Zeitschr.* 225(4/6): 247-263. 1930.—Globulins soluble in

water and in solutions of NaCl, Na_2CO_3 and NaOH were identified and shown to vary markedly from each other in their properties and COOH- (method of Obermeyer and Willheim) and NH_2-indices. For most serum proteins the NH_2 : COOH ratio falls within narrow limits. This apparent multiplicity (in agreement with Freund-Joachim) of albumin and globulin subgroups may explain the variety of their functions in the blood. Further studies will deal with the chemical composition and biological differences of these protein fractions.—*E. Pomerene.*

Med.* 54(10): 698-716. 1 fig. 1930.—In premature new-born, Hb percentage, number of erythrocytes and reticulocytes, the cell volume and especially the diameter and average surface of erythrocytes were greater than in mature new-born, whereas the Hb contents per unit of surface was much reduced. The refractometric values and number of leucocytes were less than those of mature new-born.—*M. Comel.*

9510. MALAMUD, WILLIAM, und EMELINE P. HAYWARD. Über die Verteilung der Bromionen in Blut und Liquor und ihre Bedeutung für das Problem der Blut-Liquor-Schranke. *Zeitschr. Ges. Neurol. u. Psychiatr.* 128(1/4): 295-302. 1930.—Seven cases of the transfer of bromine from the blood stream to other body fluids were studied. These experiments involved the disadvantage of using pathological fluids, since serous fluids aside from cerebrospinal fluid are not practically obtainable. No parallelism nor even relationship was found between the bromine distribution quotient and the protein quotient of blood and pathological fluids. While the protein content of pleural fluid was but $\frac{1}{5}$ that of blood the bromine quotient was somewhat greater than 1.0. Equally small quotients between blood and cerebrospinal fluids were found in case of atherosclerosis, even in cases where the protein content of the cerebrospinal fluid was but 1/400 that of the blood. The bromine distribution between blood and cerebrospinal fluid is first of all dependent on the constitution and condition of the membrane which separates these fluids. Clinical, histopathological, and chemical investigations confirm the conclusion that the amount of bromine is dependent on the condition of these membranes. The assumption of bound bromine in the blood has not been demonstrated. In view of the present knowledge of the laws of dialysis there is no justification for considering cerebrospinal fluid a pure dialysate of blood.—[*From authors' article*] (*transl. by J. M. Johlin*).

9511. MARKOWITZ, CECILE, and FRANK C. MANN. Studies on the physiology of the liver. XXI. The rôle of the liver in the formation of lymph. *Amer. Jour. Physiol.* 96(3): 709-712. 1931.—Under ether anesthesia a cannula was inserted into the thoracic duct of healthy, fasting dogs (number not stated) which 2 hrs. previously had received abundant water. No difference was observed in the flow of lymph from the thoracic duct before and after ligation of the periportal lymphatics or in the lymphagogic action of peptone in normal etherized dogs before and after ligation of the periportal lymphatics. Removal of the liver by the usual technic did not diminish the flow of lymph. The intravenous injection of peptone into a dehepatized dog was followed by the usual lymphagogic effect.

9512. MASSA, MARIO, e SALVATORE MAUGERI. Sulla presenza nel sangue di una sostanza ipoglicemizzante. [The presence in the blood of a substance producing hypoglycemia.] *Pathologica* [*Genoa*] 21(449): 138-143. 1929.—A substance was isolated from human and dog's blood by a method similar to that used by Baker, Dichens, and Dodds for the extraction of insulin from tissues. This substance when prepared from healthy human blood and administered intravenously caused a slight transitory hyperglycemia followed by severe hypoglycemia in both rabbits and guinea pigs, appearing as effective as commercial insulin. When prepared from diabetic blood there was no resulting hypoglycemia in one guinea pig. The severity of this hypoglycemia was roughly proportional to the quantity of blood employed.—*J. Vaughan.*

9513. MOGILNICKI, R. Über den Einfluss der Kombinationen von Erdalkalichloriden mit NaCl auf die Hämolyse durch Urethane. *Protoplasma* 8: 215-221. 1929.—The checking influence of alkali earth ions in combination with the Na ion in the neighborhood of the Cl ion influences urethane hemolysis. The checking maximum lies at about an equal concentration of both cations. Neither the increase nor the decrease of pH changes the type of influence of these salts. The acid reaction and also an increased CO_2 content of the blood delays urethane hemolysis while the alkaline reaction speeds it up.—*L. Moyer.*

[On the numerical variations of erythrocytes and leucocytes following asphyxia.] *Arch. Fisiol.* 29(1): 1-18. 1930.—Among 24 animals (dogs, rabbits, pigeons) submitted to experimental asphyxia, polycythemia followed in 16, the increase in the erythrocytes being 0.5-5.2 millions per cmm. In these animals the observed polycythemia disappeared after several experiments with asphyxia, and was followed sometimes by a diminution reaching subnormal values. Decreased red counts were also observed in some animals which never showed increased red cells, the diminution being 0.7-1.4 million erythrocytes per cmm. In all experimental animals the asphyxia was followed by leucocytosis, the increase of the number of leucocytes being 1000-15800 per cmm. blood. The hyperleucocytosis persisted after several experiments with asphyxia; only in a third of the animals did it disappear after numerous experiments.—*M. Comel.*

9515. MYERSON, ABRAHAM, and ROY D. HALLORAN. Studies of the biochemistry of the brain blood by internal jugular puncture. *Amer. Jour. Psychiatry* 10(3): 389-406. 1930.—Introduction of the internal jugular method has made it possible to study brain metabolism directly, especially if it is combined with the puncture of the carotid artery and, for comparison with the arm by a puncture of the brachial artery and basilic vein. Specific gravity, sedimentation rate, urea N, nonprotein N, phosphates, Ca, and Cl content of the blood in the internal jugular vein, carotid artery, brachial artery, and basilic vein are substantially the same. Sugar disappears in the transit between the carotid artery and the internal jugular vein in much the same way as in the transit between the brachial artery and the basilic vein. What the authors call brain consumption of sugar, is quantitatively as great and, in the main, tends to be greater than arm consumption of sugar. O disappears in the transit between the carotid artery and the internal jugular vein and CO_2 content increases in the same transit. The authors found no significant difference in the few cases that they have studied between the brain consumption of O and production of CO_2 and the arm production and consumption of CO_2. In 4 cases studied during anesthetization it was found that the sugar content of the blood rose very decidedly. Before anesthetization, however, there was a decided difference between the carotid sugar content and jugular sugar content. This difference tended to disappear during anesthetization.—*Authors' summary.*

Über die Alkoholextrahierbarkeit des Cholesterins aus dem Blutserum und eine auf derselben beruhende Bestimmungsmethode für freies und esterifiziertes Cholesterin. III. Über die Beziehungen zwischen Cholesterin und Eiweisskörpern. *Biochem. Zeitschr.* 225(1/3): 115-122. 5 fig.; 123-129; 130-140. 1930.—I. Solubility of cholesterol in aqueous mixtures of albumin and lecithin increases with a rise in the concentration of both substances, but there

is an antagonism in their action since the presence of lecithin reduces and reverses the effect of albumin. Ether extractibility of lecithin from known aqueous mixtures falls with increased albumin concentrations and rises upon the addition of lecithin. Adsorbability of cholesterol upon animal charcoal depends only upon the amount of albumin present, decreasing with raised concentrations. Lecithin has no apparent effect upon this process.—II. Precipitation of 1 vol. of blood serum with 19 vol. of alcohol yields a filtrate, half of which contains practically ½ the serum cholesterol. Warming of the mixture during the extraction and the addition of ether do not yield higher results. A colorimetric method based on these observations is given for the determination of free and esterified cholesterol.—III. The cholesterol protein compound described by Troensgard and Koudal is detected only when the protein-precipitant is not a fat solvent and not when serum is precipitated by alcohol. The amount of cholesterol bound to protein varies, even in the same serum, with the method of protein removal. Pure globulin precipitates fix more cholesterol than those of albumin or of both proteins. Fixation of cholesterol results when a synthetic mixture of albumin and cholesterol is precipitated with saturated $(NH_4)_2SO_4$.—*E. Pomerene.*

Legale* 50(3): 386-399. 7 fig. 1930.—Crystals of hemoglobin do not vary in accordance with the fresh, coagulated or dried state; but from study of hemoglobin from 45 embryos and fetuses and an unspecified number of subjects of various postnatal ages, Nicoletti finds that the hemoglobin of embryos, fetuses, and new-born and very young infants is distinguished by acicular shape or that of very slender, sometimes pointed, rectilinear tablets, from the hemoglobin of later life, in which the crystals are comparatively broad rectangles.

9518. NOTA, G. Nuove ricerche sulla reazione del bicromato potassico (di Taccone) nel liquido cefalorachideo. [Further studies on Taccone's K bichromate reaction in the cerebro-spinal fluid.] *Boll. Soc. Ital. Biol. Sperim.* 5(2): 33-35. 1930.—Taccone's reaction is, for its sensitivity and constancy, best adapted to determine the normality or abnormality of cerebro-spinal fluid.—*M. Comel.*

9519. OKEY, RUTH, JEAN M. STEWART, and MARY L. GREENWOOD. Studies of the metabolism of women. 4. The calcium and inorganic phosphorus in the blood of normal women at the various stages of the monthly cycle. *Jour. Biol. Chem.* 87(1): 91-102. 1930.—Figures for before breakfast values for serum Ca and P determined 3 times weekly in 12 women for periods averaging 5 weeks each are reported, together with similar figures for 6 men. A similar series of observations on plasma Ca in 14 women is also discussed. While the changes in concentration of serum Ca at any phase of the monthly cycle are not outstanding, there is some tendency to low values for Ca a few days previous to the onset of menstruation and to higher values from the 8th to the 15th days following the onset of menstrual bleeding. Day to day variations of serum Ca are smaller for men than for women. Variations in serum P are less consistent but our data at least suggest that the period of greatest proliferation of uterine mucosa preceding menstruation may be associated with a using up of inorganic P from the blood and that some extra inorganic P may be thrown into the blood stream following menstrual destruction of endometrial tissue.—*Authors' summary.*

9520. ORÍAS, O. La cantidad de hemoglobina sanguínea en hombres y mujeres adultos sanos en la Republica Argentina. [Blood hemoglobin content of normal men and women in Argentina.] *Rev. Soc. Argentina Biol.* 6(7/8): 395-409. 1930.—Newcomer's method previously controlled by Van Slyke's was used. Samples taken from finger and elbow veins give the same figure within 1% variation. Average figures were 13.38 and 14.06 gm. per 100 cc. blood for women in two different localities and between 14.32 and 15.69 for different groups of men (soldiers and students) in 4 different localities. Individual variations were great.—*J. T. Lewis.*

9522. ORÍAS, O. Factores que influencian la cantidad de hemoglobina de la sangre. [Factors modifying blood hemoglobin.] *Rev. Soc. Argentina Biol.* 6(7/8): 410-425. 1930.—Hb content is higher in ♂♂; in the newly born this sexual difference is not present. During pregnancy Hb diminishes; the decrease is accentuated by parturition, a rapid increase following so that the Hb content is higher than before pregnancy. In the new-born high figures are found, a rapid decrease occurring during the first days of life; after the 18th year, age exerts no influence. Up to 700 m. above sea level no significant differences are found; at 1200 m. the figures are significantly above normal. Military maneuvers entailing great muscular exertion produce a decrease; a rapid recovery follows. University students, army officers and non-commissioned officers have higher figures than conscripts. Weight, height and nationality of parents have no influence of the Hb content.—*J. T. Lewis.*

9523. PHILIPSBORN, E. von. Untersuchungen über den Erregungszustand der Leukozyten gesunder und kranker Menschen. *Deutsches Arch. Klin. Med.* 168 (3/4): 239-243. 1930.—Philipsborn briefly describes the technique he has used in 7 yrs.' study of neutrophile leukocytes and outlines his main conclusions. In healthy human beings the neutrophile leukocytes retain a certain normal form and structure and middling response to stimulus. In disease the leukocytes may become either less or more active, phagocytosis and agglutination (which run parallel with each other) being either increased or decreased. In the latter case the leukocytes are either paralyzed or exhausted. Excitability, paralysis and exhaustion of the leukocytes, in Philipsborn's opinion, corresponds to as many distinct forms of reaction of the organism: as excitability at the outset of a severe acute infection, paralysis in a septic infection, exhaustion during convalescence.

9524. PHILIPSBORN, E. von. Untersuchungen über die Klebrigkeit der lebenden Leukocyten gesunder und kranker Menschen. *Folia Haematologica* 41(1/2): 31-54. 10 fig. 1930.—A medium degree of adhesiveness of the vital leucocytes was present in healthy individuals. Before and after menstruation there was a decrease while during this period the adhesiveness was increased. In mild infections a high normal was noted while at the beginning of severe infections a low normal was found. In chronic nephritis the adhesiveness exceeded the normal limits.—*E. v. Philipsborn (transl. by G. D. Smith).*

9525. PHILIPSBORN, E. von. Die amöboide Beweglichkeit der Leukozyten. [Ameboid motility of the leucocytes.] *Folia Haematologica* 43(1/2): 142-191. 9 fig. 1930.—The author discusses the literature, describes his method of study, and illustrates the morphology and structure of the active leucocytes. He also reveals the influence of physical and chemical stimuli upon their motility. The deductions are: there is a normal ameboid motion of the leucocytes in the body and in vitro in health. The study of a single function of a cell is not enough; the structure, consistency, degree of sensitivity, rapidity of the ameboid action, resistance in cover glass preparations, and phagocytosis must be determined.—*E. von Philipsborn (transl. by G. D. Smith).*

9526. PLONSKIER, M. Zur Methodik der Blutausstriche und Differentialzählung der Leukocyten. *Zeitschr. Klin. Med.* 113(5/6): 753-758. 1930.—Discussion of the Goldmann and Schilling methods.

9527. PONDER, ERIC. The effect of variations in the cell content of haemolytic systems. *Proc. Roy. Soc. [London] B* 106(747): 532-542. 1 fig. 1930.—On the hypothesis that simple hemolysins act only at the surfaces of the cells of hemolytic systems, equations which describe the effect of varying the number of such cells are developed in this paper. The resulting expres-

sions are in general similar to those published in 1927; in this investigation, however, their validity is tested over a much greater experimental range and for hemolytic systems containing saponin, sodium taurocholate, and digitonin together with the cells of the ox, the sheep, the rabbit, and man.—*E. Ponder.*

9528. PONDER, ERIC. The form of the frequency distribution of red cell resistances to saponin. *Proc. Roy. Soc.* [*London*] *B* 106(747): 543-559. 1930.—A simple method is described whereby the resistances of red cells to a lysin such as saponin can be found without involved calculation. The distributions of red cell resistance obtained present a variety of forms, some being moderately skew, and some being almost J-shaped. Considerable variation is met with if the cells of different animals are used, and even with the cells of the same animal at different times. Most distributions, however, are characterised by a long "tail" in the direction of the upper extreme, to the presence of which much of the skewness of the integrated form of the curve is due. The results obtained by this method are shown to be in agreement with those given by other methods, and it is shown that similar results can be obtained from the data of several other observers.—*E. Ponder.*

9529. PONDER, ERIC, and GEORGE SASLOW. The measurement of the diameter of erythrocytes. IV. The effect of anticoagulants and of variations in drying and fixing. *Quart. Jour. Exp. Physiol.* 19(4): 319-328. 2 fig. 1929.—It is shown that the mean diameter of cells in plasma is the same whether hirudin, heparin, or oxalate is used as an anticoagulant. The mean diameter in serum is the same as in plasma. The statement of several observers that human red cells do not shrink on drying is shown to rest upon a technical error. The mean diameter of dried cells is not altered by variations in the manner of drying, nor by the use of fixatives after drying is complete.—*E. Ponder.*

9530. PONDER, ERIC. The measurement of the diameter of erythrocytes V. The relation of the diameter to the thickness. *Quart. Jour. Exp. Physiol.* 20(1): 29-39. 2 fig. 1930.—A photographic method is described for measuring the thickness of erythrocytes suspended in serum or plasma. Results of measurements of diameter, greatest thickness, least thickness, etc., are given for the red cells of man, rabbit, and sheep. The figures obtained indicate that the ratio of length to greatest thickness, and of length to least thickness are quite different in the three species of animals examined, and also that, in any one animal, there is quite a low correlation (about 0.4) between the length of the cell and its greatest or least thickness. The thickness of a cell in a rouleau is considerably less than that of the cell floating freely in plasma (1.7 μ instead of 2.4 μ), while the diameter is slightly greater (about 8.8 μ instead of 8.6 μ).—*E. Ponder.*

9531. PONDER, ERIC, and GEORGE SASLOW. The measurement of the diameter of erythrocytes VI. The diurnal variation and the effect of exercise. *Quart. Jour. Exp. Physiol.* 20(1): 41-50. 1930.—No evidence has been obtained of a "diurnal variation" or of an increase in diameter after exercise, in the case of dried human red cells. All differences which have been observed are such as might arise by chance from differences in drying, etc., and are not reproducible under controlled conditions.—*E. Ponder.*

9532. POVORINSKIJ, J. A., und W. N. FINNE. Der Wechsel des Zuckergehalts des Blutes unter dem Einfluss einer hypnotisch suggerierten Vorstellung. *Zeitschr. Ges. Neurol. u. Psychiatr.* 129(1/2): 135-146. 1930.—Experiments made with 12 sonomulists gave positive results in all cases except those which were discontinued for technical reasons or at the patient's request. In each the normal blood sugar following fasting was first determined. After feeding about 400 grams (3 gm. per kgm. body weight) of sugar or honey the blood sugar was determined at 15 min. intervals for 3 hrs. Several days later, after another period of fasting, the patient was brought into a deep hypnotic state and the suggestion made that he was receiving an equal amount of sugar or honey of similar taste. In some cases the suggestion was made to patients in a post hypnotic condition. The following conclusions were made: 1) Two possibilities are established: a) the suggestion of administering honey or sugar causes a rise in the blood sugar; b) the usual effect of sugar administration can be diminished by the suggestion of the absence of sugar actually administered. 2) Apart from any suggestions, a deep hypnotic state in itself tends to diminish blood sugar. 3) An experiment with a patient of high suggestibility shows that a change in blood sugar may be brought about while awake. 4) Results show that a participation of the sympathetic nervous system in this suggestion adds to their explanation. Even in cases of great suggestibility an increase in blood sugar is always accompanied by extreme excitation of the sympathetic nervous system through stimulations having their origin in the brain cortex. 5) In one case the suggestion of sugar administration brought on a faster increase in blood sugar than actual sugar administration. 6) Results warrant further investigation under conditions where all effects influencing the central nervous system, as shown by Cannon, are eliminated.—*J. M. Johlin.*

9533. PRAKASH, SATYA, and N. R. DHAR. Reversal of charge of serum and its coagulation and gelatinisation with acids. *Jour. Indian Chem. Soc.* 7(8): 723-732. 1930.—It has been observed that there are 2 distinct points of coagulation, when serum is coagulated by acids or salts of polyvalent cations. The first point is obtained by using dilute acids, and the second by concentrated acids. The coagulating power of concentrated acids for the second point is in the following order:—Trichloracetic > nitric > sulphuric > hydrochloric > hypophosphorous > monochloracetic > acetic > formic. When serum is coagulated by concentrated acids, it behaves abnormally toward dilution, as it has a high tendency to absorb similarly charged ions from the acids. It has been shown that in the presence of small quantities of acids, serum is sensitised, and is easily coagulated by ammonium sulphate. This is partly due to the fact that the hydrolysis of serum is checked by acids and partly because the charge on serum is reversed by the adsorption of H-ions. It has been shown that charge reversal of serum takes place near pH 5.3-5.0, when serum is coagulated by acids. It is the globulin portion of serum exclusively which is precipitated by dilute acids near the first coagulation point, while at the second coagulation point, serum albumin is also thrown down. When serum is coagulated by dilute acids, the precipitated mass is flocculent, while with concentrated acids, a gelatinous mass is obtained. Under suitable concentrations of acids, jellies of serum can also be obtained. Very stable translucent jellies of serum undergoing no marked syneresis are obtained when serum is coagulated by concentrated solutions of acetic, monochloracetic, formic and hypophosphorous acids and solid oxalic acid. Hydrochloric, nitric, sulphuric and trichloracetic acids yield opaque stable jellies of serum. The concentrations of acids necessary for the preparation of jellies are in the following order:—Trichloracetic < nitric < sulphuric < hydrochloric < monochloracetic < hypophosphorous < acetic < formic. As the concentration of serum increases, the amount of acid required to gelatinise serum in a definite time decreases.—*Authors' summary.*

9534. PRÜFER, J. Histohämorenale Verteilungsstudien. 9. Harnstoffverteilung beim Menschen und beim Hunde. *Zeitschr. Klin. Med.* 114(3): 293-308. 1930.—After intravenous injection of urea, examination of the blood and organs (in 4 men, 7 dogs) showed a gradual elimination of the urea from the blood over a period of 24 hrs., which was the same for men as for dogs. An unusually great affinity for urea was manifested by the musculature which may retain over ½ of the injected quantity. The skin is next in order as an important depot for urea, while the liver is the third. The concentrating function of the kidney closely parallels the urea

concentration in the urine. It is greatest at the time when the organ concentration is highest, and after 2 hrs. declines, though the urea elimination continues to rise. The above series of organ concentration and blood urea values indicate, without doubt, that the theory of simple diffusion of urea into the tissues from the blood, as Marshal & Davis believe they have established, cannot be entertained. The release from the tissues takes place slowly, from liver and muscle only after 12 hrs., from the skin after 24 hrs. On this basis can be explained the sustained high blood concentration. The release, however, occurs without increase in the blood content. No interval excretion in the bile could be demonstrated. In the first 30 min. the urea could not be detected in the tissues. It cannot be decided, whether the fixation of the urea is to be explained by unaccounted tissues, which cannot be weighed (musculature) or by some particular unknown mechanism. Comparison with similarly tested substances shows full agreement with results obtained with phenolphthalein; that there exists no proportion between blood and tissue concentration. The slow elimination of urea from the body is similar to the retention of indol as shown by Olivet.—*Author's summary (transl. by M. Lederer).*

9535. PUPILLI, G. Sul comportamento di alcune sostanze coloranti di fronte ai globuli rossi di diversi animali. [Behavior of certain dyes toward erythrocytes.] *Ateneo Parmense* 2(6): 573-583. 1930.—Three basic (methylene green, methyl green, and rosaniline) and 1 acid (tropeolin) dye were used. Arranged in descending order according to the capacity of a given mass of the respective erythrocytes to absorb basic coloring matter, the experimental animals used are: rabbit, guinea pig, dog, white mouse, horse, hog, cat, ox, goat and ram. The descending order for ability to take up tropeolin is: hog, ram, goat, ox, cat, rabbit, white mouse, dog, guinea pig and horse, which is the same as the descending order for lipid content.

9536. RADICE, L. Il comportamento della riserva alcalina e del pH del sangue nelle emorragie e nelle trasfusioni. [Behavior of alkaline reserve and blood pH in hemorrhage and in transfusions.] *Arch. ed Atti Soc. Ital. Chir. [Roma]* 34: 473-474. 1927[1928].—Experiments on the dog. Method of Van Slyke and Cullen used.

9537. RAY, G. B., and G. H. PAFF. A spectrophotometric study of muscle hemoglobin. *Amer. Jour. Physiol.* 94(3): 521-528. 5 fig. 1930.—Muscle pigment was studied in situ, by a method based on determinations of the refraction curves from uninjured muscle immediately after removal from the animal (dog and rat), which had been perfused until the perfusing fluid (0.9% NaCl) was practically colorless. The results show that muscle hemoglobin is distinct from blood hemoglobin, in that the absorption curves of reduced and oxyhemoglobin both show a characteristic shift (not due to fermentation, since occurring in situ in fresh muscle) toward the red end of the spectrum. Kundt's rule does not hold in this case, since if it did the comparatively high concentration of optically active substances in the muscle should cause a more marked shifting of the spectrum toward the red end, as compared with the effect of the dilute extract, which is not true, since the α and β bands occur at the same wave length in both extract and in situ. The shift in the position of the α band resulting from carboxyhemoglobin formation (3 mμ instead of 6 mμ) is not the shift one would predict if the pigments were identical with blood hemoglobin. Without doubt, the authors say, the pigment fraction of both hemoglobins is the same, but the protein fraction is different.

9538. RIEBELING, CARL. Über das Vorkommen von präformiertem Ammoniak im Liquor cerebrospinalis. *Zeitschr. Ges. Neurol. u. Psychiatr.* 128(1/4): 475-477. 1930.—In 17 clinical cases, including epilepsy, paralysis, microcephalia, congenital syphilis, skull trauma and cerebral cyst, preformed NH_3 varied from 0 to 0.5 mgm. %, the findings being especially high in 2 cases of epilepsy with frequent attacks. In 4 cases in which the fluid of different spaces was drawn different NH_3 content was found in the fluids of the different regions.

9539. RODERICK, LEE M. A problem in the coagulation of the blood. "Sweet clover disease of cattle." *Amer. Jour. Physiol.* 96(2): 413-425. 1931.—The feeding of damaged sweet clover hay and silage to cattle results in fatal hemorrhage preceded by a characteristic delay in the coagulation of the blood. This paper deals with a consideration of the alterations in the blood which are concerned in the coagulation process. Analytical work on the blood of a series of animals fed on damaged sweet clover indicates that there may be some depression in the blood fibrinogen during the feeding trials, yet the values obtained were within the probable error of a series of determinations on normal cattle. This work shows that the delayed coagulability of the blood in sweet clover disease involves a reduction in the prothrombin and that the diminution parallels the delay in the coagulation time. No experimental evidence has been found to indicate that the delay in coagulation is due to increase of an inhibitory principle of the nature of heparin or antithrombin. Estimation of the blood Ca together with other studies show that this condition is neither caused by nor does it involve a deficiency in the metabolism of Ca. The progressive decrease in the quantity of available prothrombin in the blood of animals fed on the damaged sweet clover seems to be quite independent of the number of platelets present which remains at about the normal level until hemorrhage occurs. The treatment of many animals which have developed serious hemorrhage by the intravenous injection of freshly defibrinated normal bovine blood has resulted in a large proportion of recoveries.—*Author's summary.*

9540. RONA, P., und W. FABISCH. Untersuchungen über den Blutzucker. II. *Biochem. Zeitschr.* 227(1/3): 205-220. 1 fig. 1930.—The concordance in results previously reported for sugar in normal human blood with the Hagedorn-Jensen and colorimetric methods was again secured. The same agreement in results between the above methods was obtained in studies on experimental adrenaline hyperglycemia in rabbits. In case of human diabetics the difference between the values obtained by the two methods was frequently greater than could be explained by any experimental error. The difference did not definitely indicate a predominance in the direction of one method over the other. The blood sugar of rabbits in hypoglycemic shock indicated a predominance in favor of the Hagedorn-Jensen method. Experimental errors can be excluded.—*Authors' summary (transl. by E. G. Schmidt).*

9541. ROSENBLUM, D. E., und K. MENDJUK. Veränderungen in der Reticulocytenzahl im Menschenblute bei bis zur Ermüdung geführter Muskeltätigkeit. *Arbeitsphysiologie* 2(5): 395-408. 1930.—The reticulocytes in 200 fields were counted in blood taken at intervals from subjects at rest before immediately following and during the recovery periods after various forms of muscular activity. An increase in the number was nearly always found, depending upon the strenuousness of the work. The greatest increase was from 182 before to 482 after a 15 km. ski run with a load of 10 kgm. The next in order was before and after boxing with untrained subjects (6 min.) with a change from 197 at rest to 455 after boxing, and 50 mins. later 215. Walkers and load carriers in the sanitary division showed but slight changes. In general the return to the normal level was complete in 3 hrs.—*T. M. Carpenter.*

9542. SAMSON, KURT. Der normale Liquor cerebrospinalis im ersten Lebenstrimenon. *Zeitschr. Ges. Neurol. u. Psychiatr.* 128(1/4): 494-503. 1930.—The spinal fluid in the newborn shows unusual features in the cell-count and the values for protein and sugar. The mastic reaction is negative. A positive mastic reaction is indicative of intracranial injury at birth (if other causes can be ruled out). Protein content is higher than normal, approaching the normal throughout the first 3 mos. In premature infants the approach to normal is slower. The

determination of the protein ratio is more objective and more useful than the simple protein reactions, the interpretation of which is rather subjective. The gold sol and Takata-Ara reactions are not suitable.—*B. S. Walker.*

9545. **SCHERINGER, W. Beitrag zur Kenntnis des Blutjodspiegels beim Weibe unter physiologischen Bedingungen. [Iodine level of the blood in women under physiological conditions.]** *Arch. Gynäkol.* 143(2): 319-337. 1930.—The I level of the blood on an I-poor diet was found to be stable at about 25% decrease after 2 days (5 ♂, and 5 ♀ in the intermenstrual period). During menstruation the I level in the blood is about 25% higher than during the intermenstrual period (15 cycles were followed in 8 ♀♀).

9546. **SCHMITZ, ADOLF. Zur Struktur des Hämocyanins.** *Naturwissenschaften* 18(37): 798. 1930.—Note.

9547. **SCHÖNFELD, HERBERT. Über den Einfluss der Ernährung auf die Blutmilchsäure und den Blutzucker des Säuglings.** *Jahrb. Kinderheilk.* 128(5/6): 351-393. 1930.—Observations on a number of series of infants indicate that in repose the blood lactic acid is about the same on natural and artificial food. Very young infants on human milk show perhaps a somewhat higher blood lactic acid. After feeding with lactic acid milk the blood lactic acid in repose shows (generally but not invariably) a tendency to rise. With HCl milk feeding there is a tendency to slight fall of blood lactic acid. Under continued feeding with lactic acid milk there is a distinct tendency for the fasting blood-sugar to fall while the blood lactic acid rises. After feeding with HCl milk the fasting blood sugar tends to rise. There is no clearly recognizable connection between blood lactic acid and hunger hypoglycemia. The hunger hypoglycemia occurring after 12-hr. interval between feedings falls to a lower point if the previous feedings have been with acidified milk (lactic acid and HCl) than if with non-acidified milk. Addition of large amounts of sugar increases the rise in blood lactic acid observed on feeding with lactic acid milk.

9548. **SCHRETTER, G., und H. NEVINNY. Der Blutzucker in den ersten Lebenstagen.** *Zeitschr. Geburtsh. u. Gynäkol.* 98(2): 258-276. 1930.—The blood sugar after fasting was determined during the first week in the case of 38 newly born children. 196 determinations show, in general, remarkably low results. 48% were less than 0.070 gm. % and were distributed among 36 of the 38 cases investigated. 15 determinations distributed among 14 cases showed 0.045 gm. % or less, falling into that zone where pronounced hypoglycemia would be indicated in a normal individual. Few cases of exceptionally high values were found. The variation from day to day in individual cases was generally considerable. The blood sugar after fasting was exceptionally low at the beginning, but after a week generally reached the average, and showed the average variation, of a normal individual. Various explanations for these findings are taken into account. Special significance is attributed to the behavior of the endocrine system of the newly born. The first nourishment taken often appears to have a definite effect on the change which occurs. An increase in the fasting blood sugar appears to precede an increase in weight.—*Authors' summary (transl. by J. M. Johlin).*

9549. **SCHWARZ, KARL, und EGON MEZLER-ANDELBERG. Untersuchungen über die Beziehung des Blutzuckergehaltes zur Milchproduktion bei Kuhen. [Blood sugar content and milk production in cows.]** *Biochem. Zeitschr.* 194(4/6): 362-375. 1928.—Even with good feeding the blood sugar in 200 lactating cows was lower than in non-lactating cows. The average blood sugar content for the latter was 82 mgm. per 100 cc., measured by the Hagedorn and Jensen method. In 5% of the lactating cows blood sugar values were 40-50 mgm.; 20%, 50-60 mgm.; 45%, 60-70 mgm.; 20%, 70-80 mgm.; 10%, over 80 mgm. No relation was found between blood sugar and amount of milk produced, but the blood sugar increased as lactation advanced. No connection was found between hypoglycemia and coma after calving and the inception of lactation.—*S. A. Asdell.*

9550. **SIMMERS, MAURICE H. An investigation of the physical structure of fibrin by x-ray crystal methods.** *Amer. Jour. Physiol.* 94(3): 497-500. 2 fig. 1930.—Experiments were undertaken to answer the question: Does the fibrin of a fibrin gel exist in a crystalline condition? The x-ray diffraction pattern method was used to answer this question because it furnishes the most rigid test for crystallinity. The fibrin of a normal blood clot gives no diffraction pattern. "Fibrin" formed by adding $CaCl_2$ to oxalated plasma gives a diffraction pattern. This pattern can be caused by adding $CaCl_2$ and K oxalate to dry powdered fibrin from a normal clot which itself gives no diffraction pattern. Fibrin prepared by adding $CaCl_2$ to citrated plasma gives no diffraction pattern. The experiments clearly show that the fibrin, whether it be taken from a normal blood clot or from a clot formed by adding $CaCl_2$ to citrated or oxalated plasma, has not itself a definite space lattice, although under certain conditions crystalline material may be associated with it. Fibrin, therefore, is not a crystalline substance.—*Author's summary and conclusions.*

9551. **SPICER, A. The vermiform appendix of the ram.** *Vet. Rec.* 10(12): 255. 1930.—Twenty ram lambs were castrated. Distinct evidence that the filiform appendix had begun to atrophy was found 2 mos. afterward.

9552. **SRIBHISHAJ, KHUN, WILLIAM B. HAWKINS, and GEORGE H. WHIPPLE. I. Bile pigment and hemoglobin interrelation in normal dogs.** *Amer. Jour. Physiol.* 96(2): 449-462. 1931.—The renal type of bile fistula permits bile pigment observation during long periods with the dog in perfect condition. In the authors' hands this type of fistula [4 experiments] gives bile pigment secretion figures which must approximate physiological normalcy. The bile pigment output per 24 hrs. falls slightly below the figures recorded in the literature (av. 4-6 mgm. per kgm.). The individual dog has its own total bile pigment output level which under uniform conditions shows a remarkably constant average value from month to month. This total output is not changed following gain or loss of weight but obviously the mgm. per kgm. must change. Dog Hb solutions given intravenously under carefully controlled conditions show an increase in bile pigment elimination corresponding to 90-95% of the expected increase if there were a quantitative transformation of Hb to bile pigment. Theoretically 1 gm. Hb is equivalent to 40 mgm. bilirubin. The closed sterile bile fistula [3 experiments] is carried as control to the renal-bile fistula. This closed fistula shows a bile pigment increase due to Hb injection which is less than the renal fistula and averages 75-80% of the theoretical return.—*Authors' summary.*

9553. **SSYSGANOW, A. N. Zur Untersuchungstechnik des Lymphsystems. [The technique of the study of the lymphatic system.]** *Anat. Anzeiger* 70(13/17): 288-293. 2 fig. 1930.

9554. **STEWART, G. N. The conductivity of erythro-**

cytes compared with that of serum. *Amer. Jour. Physiol.* 90(1): 194-209. 1 fig. 1929.—The author describes method for determining k_1/k in defibrinated rabbit's blood (k_1=specific conductivity of serum; k sp. cond. of sediment). Fig. 1 shows the relationship between k_1/k and p; cc. of serum in 100 cc. blood p is calculated from the formulae: $p=k/k_1$ [174-k(5°)]; $k_1/k+\frac{1}{2}=174/p-3/100\text{-}p$; $k_1/k+\frac{1}{2}=175/p-p/400$. The last formula can be written $k_1/k+\frac{1}{2}=(7\text{-}p^2)/4p$, where p is the proportion of 1 cc. of the blood which consists of serum. The graph shows values down to $p=11.5$; $k_1/k=127.3$, the highest value measured. Results with the electrical and hematocrit methods are compared with the colorimetric method and Hoppe-Seyler's. Specific conductivity of well centrifuged sediments was found to be considerably less than 0.01 that of blood. (1/103.6, 1/123, 1/127.3, 1/111.) In two it was 1/80, 1/88.6. There is no reason to believe that lower values than those measured can be obtained for sediments. In the best separated sediments some serum is present so that k for erythrocytes is less than that measured in any sediment. 1.3% serum in sediment would account for its k. This amount of serum would be more than furnished by a film of serum 0.01 μ around the cells; would be 1.7% serum. At the other end of the curve from $k_1/k=1$, 100% serum as k_1/k increases curve approaches the abscissa asymptotically. When hemolysis occurs k_1/k increases due to increased conductivity of sediment with practically no change in serum content. Viscosity of sediment also diminishes. Addition of trace of saponin to sediment increased conductivity 20 X and diminished viscosity.—*M. R. Freeland.*

9555. **STUBER, BERNHARD. Die Blutgerinnung als kolloidchemisches Problem.** *Kolloid Zeitschr.* 51(1): 144-152. 3 fig. 1930.—Previous papers on this subject by the author and his associates are summarized. The thrombin-fibrinogen coagulation is an artificial system and thrombin, as prepared, is an artificial substance. Thrombokinase is no activator but has a physico-chemical mode of action modified by pH and surface activity. Natural blood-coagulation is initiated by glycolysis and associated acid formation. Flocking is favored by the resulting neutralization of charges on plasma proteins and by surface-active substances such as thrombokinase. Agents which check coagulation check glycolysis and usually stabilize the colloid-chemical state of blood proteins. Calcium has only a physico-chemical rôle since it acts in harmony with its position in the Hofmeister ion series. The author believes the enzyme theory of coagulation must be abandoned.—*B. Stuber* (*transl. by D. B. Dill*).

9556. **SUHRMANN, RUD. Quantitative Untersuchungen im Absorptionsspektrum des Blutes und seiner Bestandteile.** *Physik. Ztschr.* 30: 959-965. 8 fig. 1929.—A résumé is presented of the author's work with collaborators, previously published in *Biochem. Ztschr.* 184: 216. 1927; *Strahlentherapie* 27: 572. 1928; *ibid.* 30: 145. 1928; *ibid.* 32: 389. 1929, on the ultraviolet absorption spectra of plasma and of hemolyzed blood corpuscles from human beings of different sexes, ages and conditions of health and from healthy, rachitic and xerophthalmic rats. The absorption spectra of the human bloods were identical regardless of the nature of the source but those of the rat bloods varied in a characteristic manner with the condition of the animal. These variations are attributed to a change in the constitution of hemoglobin in the case of rickets and to a change in the make-up of the plasma in the case of xerophthalmia.—*C. V. Shapiro.*

9557. **TAKEDA, MASAO. The influence of the intravenous infusion of Ringer-Locke's solution on the coagulability of the blood and the cause of the change in the blood coagulability.** *Folia Pharmacol. Japon.* 9(2): In Japanese, 65-74; English summary, 7. 1929.—Ringer-Locke's solution was infused into veins of rabbits at body temp., and at the rate of 10 cc. per kgm. per min. in various quantities, viz. 50, 100 and 200 cc. per kgm., and the clotting time of the blood as well as the quantity of fibrinogen, thrombin, thrombokinase and Ca in it was determined. Blood coagulability was augmented by the infusion of Ringer-Locke's solution. This augmentation was greatest immediately or 15 min. after the infusion. The greater the quantity infused, the longer the augmentation of the blood coagulability lasted, and the more marked it became. The fibrinogen content in the blood showed no evident changes whereas the thrombin and the thrombokinase content were, in general, augmented with the increase in the blood coagulability. The blood Ca was scarcely increased by the infusion.—*From author's abstract.*

9558. **TORYU, YOSHIYUKI. Changes in the blood picture, and in the oxygen capacity of the blood haemoglobin of the carrier-pigeon following splenectomy.** *Sci. Rept. Tôhoku Imp. Univ. 4th. Ser. Biol.* 5(2): 391-402. 1930.—Removal of the whole spleen from the adult carrier-pigeon usually produces at once a decrease in the number of erythrocytes. In about a week they begin to increase and in about 7 weeks are usually more numerous than before the operation. The erythrocyte decrease is associated with a considerable polychromatophile increase during the first 2 weeks, suggesting increased hemopoiesis. The hemoglobin content in every instance after splenectomy shows lower values than would correspond with the total erythrocyte counts. Removal of the whole spleen in the adult pigeon produces an increase in the number of leucocytes, suggesting a postoperative leucocytosis. They return to normal after about 2 weeks. There are noteworthy changes concerning the differential leucocyte count: The number of lymphocytes decreases progressively after splenectomy, while the pseudoeosinophiles show a reverse change. Splenectomy in the adult carrier-pigeon causes the appearance of a non-oxygen-carrying hemoglobin varying in amount from 1 to 25% of the total blood hemoglobin. This inactive hemoglobin seems to be associated with the appearance of polychromatophile cells.—*Author's summary.*

9559. **VERZÁR, F., und A. von KÚTHY. Die physiologische Bedeutung der Hydrotropie.** *Biochem. Zeitschr.* 225(4/6): 267-277. 1930.—The hydrotropic action of bile acids includes the power to make water solutions of fatty acids, quinoline, camphor, diphenylamine, cholesterol, etc. Not only is the solubility of the substances in water raised but they are found in greater dispersion and become more diffusible. Hydrotropic action is not of a general nature; fatty acids can not be brought into solution by all hydrotropic salts. Diffusion experiments show that some organs contain hydrotropic substances other than bile acids. This indicates an explanation of the way in which substances insoluble in water can circulate in the organism. The hydrotropic power of intestinal juices plays an especially important rôle in the absorption of these insoluble substances.—*Authors' summary* (*transl. by C. M. Goss*).

9560. **VILLA, LUIGI. Sull'origine dell'emoglobina. [On the origin of hemoglobin.]** *Arch. Fisiol.* 28(2): 233-236. 1930.—At an early phase of maturation of hemoglobin cells there exists a primitive endonuclear affinity for acids. The author derives therefrom the hypothesis of an origin of hemoglobin by way of an endonuclear synthesis.—*M. Comel.*

9561. **VOGT, E. Studien zur Biologie des Liquor cerebrospinalis. III. Untersuchungen über den Gehalt des Liquor cerebrospinalis an Chlornatrium bei gesunden und kranken Frauen. IV. Untersuchungen über die Wasserstoffionenkonzentration des Liquor cerebrospinalis bei der gesunden und kranken Frau.** *Arch. Gynäkol.* 143(2): 430-433; 434-437. 1930.—III. To determine a possible ovarian influence on the NaCl content of the cerebrospinal fluid, examinations were made of material obtained during spinal anesthesia from 105 women with the most varied obstetrical and gynecological conditions. The NaCl content in healthy women showed great variations (0.725-0.800%). Normal and pathological pregnancy and the menstrual cycle did not influence the NaCl content. It showed no characteristic changes in the most important diseases of the reproductive organs.—

IV. Electrochemical examinations of the cerebrospinal fluid with the quinhydrone electrode showed that the pH in the healthy woman is between 7.4-7.6. In investigations on 244 women [pregnant, parturient, puerperal and women with various diseases of the reproductive organs, especially tumors of the uterus and the ovaries], the pH was not changed.

9565. **YANKOVSKY, W. D. Sur les propriétés physiologiques de l'héparine Howell.** *Jour. Physiol. Path. Gén.* 28(3): 579-586. 1930.—Howell's heparin is a good and harmless preservative of blood in vitro, and is recommended for perfusion experiments. Its action is destroyed by tripaflavine, rivanol and quinidine. The minimal stabilising dose for the rabbit, in vivo, is 0.1 of a unit per kgm. body-weight. The blood regains its coagulability in 3-4 hrs., but the duration of action may be increased by vascular disconnection of kidney, pancreas, spleen and alimentary tract.—*W. R. Fearon.*

9566. **YEAGER, J. FRANKLIN. Studies on the acceleration and inhibition of hemolysis. II. The effect of sugar solutions on the resistance of hypotonic hemolytic systems.** *Amer. Jour. Physiol.* 96(2): 484-493. 1931.—*M*/3.6 solutions of sucrose, levulose, rhamnose, maltose, lactose, and, in general, dextrose, produce an increase in the resistance of the hemolytic system, when added to the system as component (a). *M*/3.6 solutions of galactose and some samples of dextrose, produce a decrease in the resistance of the hemolytic system, when added as component (a). Sucrose, levulose, rhamnose, dextrose, and galactose produce a relative decrease in the resistance of the hemolytic system, when added as a portion of the red cell suspension medium, as compared to the increase or decrease of resistance, produced when solutions of these sugars are added as component (a). Maltose and lactose produce a relative increase in the resistance of the hemolytic system, when added as a portion of the suspension medium, as compared to the increase of resistance produced when they are added as component (a). Within limits, the greater the quantity of sugar added to the hemolytic system the greater the immediate or the prolonged effect that is produced. A number of experiments are described which show that changes other than the entrance of water into the red cell occur in the process of hypotonic hemolysis.—*Author's summary.*

9567. **ZEIDBERG, LOUIS D. A quantitative determination of the changes in hemoglobin concentration, volume of red cells, and basophilia in the blood of rabbit fetuses at various stages during the last third of pregnancy.** *Amer. Jour. Physiol.* 90(1): 172-183. 2 fig. 1929.—The general plan in the present investigation was to determine the hemoglobin content of the blood by Kennedy's method, using a Du Boscq colorimeter. This colorimetric estimate was checked by histological examination of the red cells in smears prepared by Jenner's modified Romanowsky stain, and the proportion of basophilic red cells was counted. Further verification of the hemoglobin concentration was obtained by hematocrit determinations giving the volume of red cells per unit volume of blood. In all cases the blood of the mother was studied, as well as of the fetuses. Observations were made on 87 fetuses of 19 rabbits during the last 3rd of gestation. It was found that the hemoglobin concentration increased from an average of about 8 gm. per 100 cc. of blood at 22 days to about 12 gm. per 100 cc. of blood at term, or roughly an increase of 50%. The volume of red corpuscles increased from about 28 volumes % at 22 days to about 42 volumes % at term, or roughly an increase of 50%. The percentage of basophilic red cells in histological preparations decreased from about 28% at 22 days to about 4% at term.

9568. **ZIH, A. Die hämopoetische Wirkung von verfütterter Milz.** *Pflüger's Arch. Ges. Physiol.* 218(5/6): 736-748. 6 fig. 1928.—Rabbits bought in the general market were fed a basic diet of hay, oats, and turnips. The rabbits were kept for 1 wk. under as uniform conditions as possible. Red blood cell counts were made by Bürker's method. Normal rabbits showed variations from 4.31 million to 7.72 million erythrocytes per cmm. The reaction of rabbits to spleen feeding depended on the constitution of the rabbit. In general, however, large doses of spleen increased red blood cell production, and small doses decreased it. In animals with a red blood cell content of less than 5.70 million the decreasing action of spleen at all dosages is very slight; the hemopoietic action very marked. Hemolysis in anemic rabbits could be produced only when the largest doses of spleen that could be tolerated were used, and even then hemolysis was not always produced. In rabbits with high blood counts spleen feeding in large doses produced marked decrease in red blood cell number, in small doses it had a weak or no hemopoietic action. Experiments conducted with men showed that spleen feeding increased blood formation in anemic patients, but did not influence the blood cell count greatly in normal individuals. There may be 2 substances in spleen, 1 a hemolytic and the other a hemopoietic. In large doses the action of the hemolytic substance is more marked than that of the hemopoietic, and conversely, in small doses the action of the hemopoietic is more marked than the hemolytic.

9569. **ZIH, A. Untersuchungen über den auf die Blutbildung wirksamen Stoff des anämischen Serums.** *Pflüger's Arch. Ges. Physiol.* 225(5/6): 613-619. 3 fig. 1930.—No bilirubin was found in the serum of [5] animals [rabbits ?] rendered anemic by bleeding. Hemoglobin was demonstrable in the serum of 9 only out of 20 anemized animals 24-36 hrs. afterward; only those sera that contained dissolved hemoglobin had a hematopoietic effect. The sera of normal animals (apparently 6) also had this effect if hemolysis was produced in taking the blood.—*From author's summary (transl.).*

9570. **ZIH, A. Einfluss des Chlorophyllgehaltes vom Futter auf die Blutkörperchenbildung.** *Pflüger's Arch. Ges. Physiol.* 225(5/6): 728-736. 4 fig. 1930.—Of 11 rabbits, 5 received chlorophyll-free food; the others were fed green food. Oral administration of chlorophyll in both groups produced erythropoiesis, with marked individual variations as to size of effective dose, attributable, as indicated by 5 other experiments, to variations in the chlorophyll content of the food. Increase of the chlorophyll dose beyond a certain point, however, did not increase and might even decrease erythropoiesis. Change from green food to chlorophyll-free diet almost always caused erythropenia; addition of chlorophyll or change back to green food reversed the blood change.

ENERGY METABOLISM

9571. **BENEDICT, FRANCIS G., and CORNELIA GOLAY BENEDICT.** The energy requirements of intense mental effort. *Proc. Nation. Acad. Sci.* 16(6): 438-443. 1930.—With the helmet and spirometer type of respiration apparatus the O consumption or the energy needs of 5 men and 1 woman were measured during periods of mental repose and mental activity. The mental effort consisted in the solution, without aid of paper and pencil, of a number of problems in multiplication and addition. To rule out the influence of excitation or "attention," the metabolism was likewise measured during periods of response to a flashing light or an electric buzzer, the subject lightly tapping a telegraph key whenever the stimulus occurred. Simultaneous graphic records were obtained of the heart rate, the respiration rate, and the ventilation of the lungs. The results of this investigation show that with intense, sustained mental effort, such as in multiplication, there is a noticeable increase in the heart rate, a rather considerable change in the character of the respiratory movements, an increase in the volume of air passing through the lungs, a small increase in CO_2 production, a smaller increase in O consumption, and consequently a slight increase in the apparent respiratory quotient. The increase in O consumption, which may be taken as the best index of energy transformations, is such as to suggest that the increase in heat production as a result of intense mental effort of this type can hardly be of the order of more than 3 or 4%. In view of the sense of extreme, almost overpowering fatigue in both mind and body following sustained mental effort, it is surprising that mental effort has such an insignificant effect upon the general metabolism or level of vital activity.—*E. A. Wilson.*

9572. **BENEDICT, FRANCIS G., and JOSEF M. PETŘIK.** Metabolism studies on the wild rat. *Amer. Jour. Physiol.* 94(3): 662-685. 4 fig. 1930.—Numerous measurements of the basal metabolism of the albino rat have been made. They are not wholly uniform. Even in the researches in which the Nutrition Laboratory has coöperated measurable differences in the basal metabolism of this animal have been noted. Thus, Horst, Mendel, and Benedict conclude that the basal metabolism of adult ♀, albino rats, living at an environmental temp. of 26° C. but measured at 28° C., about 24 hr. after food, is from 600 to 700 calories per sq. meter of body surface per 24 hr. Benedict and MacLeod conclude that a standard value for ♀ albino rats would be 720 calories and for ♂ rats 800 calories. In the authors' series of wild rats the basal metabolism at 28° C. was in all cases distinctly high. The average of all the basal measurements is 942 calories and the average of those obtained only on the 1st day of measurement is 1010 calories. Here it is a question whether domestication has a rapid and pronounced influence, or whether it is a matter merely of adjustment of the wild rat to a new environment with less fright. The authors believe that the terror did not obtain, even in these 1st day's measurements, for the extraordinarily quiet repose of these animals astonished them. The basal heat production of the wild rats per 200 gm. body weight per 24 hr. was likewise higher in the 1st measurement than in subsequent measurements, but averaged 27 or 28 calories as compared with an average of about 20 calories found with the albino rats measured at 28° C. On either basis of computation, therefore, the wild rat has a perceptibly higher metabolism than the albino rat.

9573. **BORGSTRÖM, H., E. ELFVENGREN, C. O. LÖVEGREN, und C. SUNDSTRÖM.** Der Stoffwechsel beim Billardspiel. *Skand. Arch. Physiol.* 60(5/6): 244-246. 1930.—The study was made on 5 players, each of whom played twice, both times alone. The total exhaled C per hr. ranged from 14.97 to 20.82 gm. and averaged 18.08 gm. There was also considerable variation in the C production in different hours by individual subjects, the differences ranging from 1.20 to 4.70 gm. The total metabolism per kgm. per hr. varied between 2.3 and 3.2 cal. with an average of 2.9.

9574. **BORRA, EVA.** La perspiratio insensibilis in rapporto con la temperatura della cute. [Perspiratio insensibilis and temperature of the skin.] *Arch. Fisiol.* 28(3): 490-502. 3 fig. 1930.—The perspiratio insensibilis and the temp. of the skin were simultaneously recorded in limited areas of the skin, over which the temp. of air was modified. The temp. of air and of skin coincide at 33.5°-34° C.; below these values the temp. of the skin is higher than that of air. Above the said values the temp. of the skin grows higher following the rise of that of air. As long as a positive thermic gradient exists between skin and blood, the temp. of the skin is lower than that of blood; otherwise it is the same. The perspiratio insensibilis is constant if the skin temp. varies from 29.7° to 32.5°. When higher temps. are reached it is rapidly increased: the rates are 7 times higher at 33.5°. The evaporation is to be considered, under these conditions, as given by 2 factors, one being the perspiratio insensibilis, the other the sweating. The former is, within the limits studied, independent of the temp. and secretory activity of the skin. The sweating is on the contrary an exponential function of the temp. of the skin, which function does not follow Van't Hoff's law, and is probably acted upon by influence of the temp. on the secretory processes as well as by vasomotor variations.—*M. Comel.*

9575. **BORSOOK, HENRY, and HOWARD M. WINEGARDEN.** On the free energy of glucose and of tripalmitin. *Proc. Nation. Acad. Sci.* 16(9): 559-573. 1930.—The theoretical maximum amount of work obtainable from the oxidation under physiological conditions of glucose, and of tripalmitin, is computed from the standard free energies and heats of combustion of these compounds. Such computations show that the theoretical difference in efficiency, i.e., the ratio of the theoretical maximum work obtainable to the total energy change, is little different for glucose and for tripalmitin. Similarly it is calculated that the conversion of tripalmitin into glucose involves a release of energy approximately equivalent to 20% of the theoretical maximum work available from the oxidation of tripalmitin. Since experimental evidence in the literature indicates that the difference in efficiency between fat and carbohydrate as fuels for muscular work is much less than 20%, it follows either that fat is burned as such in the provision of energy for muscular work, or that the energy released

in the hypothetical conversion of fat into carbohydrate is not dissipated as heat, but is used for work; and the efficiency of utilization of this energy is little different from that in the consumption of carbohydrate. The process of conversion of glucose into tripalmitin probably exerts a considerable "specific dynamic action" on metabolism. The evidence in the literature on plants and animals is in accordance with these thermodynamic predictions.—*H. Borsook.*

9576. BRENDLE, EUGENIE. Gaswechsel und Körperzusammensetzung. *Pflüger's Arch. Ges. Physiol.* 226(1): 108-112. 1930.—Adult rats were fed either on a diet poor in protein and fat or in one rich in these foodstuffs. The O consumption was determined and also the specific dynamic action of mince meat and cheese. The animals were killed, the total N of the body was determined and (in 10 animals) the total fat content; with these values the gaseous exchange was compared. The smaller animals had a higher basal metabolism (per kgm.) than the larger. The fatter the animals, the lower the values for basal metabolism and specific dynamic action. The N content of rats of different size was proportionally the same, so that no correlation was observed between O usage per kgm. and N content.—*H. C. Bazett.*

9577. CAREDDU, G. Studi su bambini normali ed ipotrofici nel primo biennio di vita in rapporto con lo sviluppo della superficie corporea direttamente misurata. II. Metabolismo basale. [Studies on normal and hypotrophic infants during the first two years of life in relation to the increase in body surface directly measured. II. Basal metabolism.] *Riv. Clin. Pediatr.* 28(7): 553-573. 1930.—The basal metabolism (B.M.) of the newborn is very low; in 9 newborn infants the av. was about 520 cal. per sq. m. per 24 hrs. It increases rapidly with increase in food intake. The B.M. of 12 normal infants during the 1st yr. of life, referred to the body surface directly measured, corresponded more closely to the figures of Talbot than to those of Aub and DuBois. The B.M. of individual normal infants of the same age varied within wide limits corresponding to their customary food intake. The higher values of the B.M. in normal infants occurred with a food ration sufficient to produce a regular increase in weight, although in all cases the B.M. test was made after a fasting period of not less than 8 hrs. Study of 14 hypotrophic infants showed that, when undernourished, the B.M. was less than that of normal infants of the same age, but when they could take a ration sufficient to produce increased weight, the B.M. was always higher than that of normal infants of the same age. The B.M. was not always the same for each individual, but, in spite of the fast preceding each test, varied with the customary food intake of normal or hypotrophic infants.

9578. EFIMOFF, W. W., O. A. SALZGEBER, P. P. MITROFANOFF, M. N. SARCH, A. P. KRJUTSCHKOWA, N. A. ITINA, und A. J. LEWINA. Die vergleichende physiologische Wirkung der Arbeit beim individuellen, beim manipulationsweisen und beim Konveyorsystem. *Arbeitsphysiologie* 3(3): 218-229. 1930.—The purpose of the study was to determine the comparative energy expenditure in the ironing by hand of men's shirts in a laundry in Moscow in which the work was carried out by 3 different systems: 1, in which all parts of the garments were ironed by one worker: 2, in which the work was divided into 5 manipulations, each one being performed by a separate person who passed the garment on to the next worker; and 3, in which the shirt was ironed by separate workers in manipulations but conveyed from one to another by a moving belt. The maximum number of shirts was ironed when the conveyor system was used, and the minimum when a shirt was ironed entirely by one person. The average O consumption throughout the working day varied from 325.7 ccm. per min. with the conveyor method to 377.5 ccm. by the separate manipulation method. The O absorption per piece of work varied from 5487 ccm. with the conveyor system to 9181 cc. by the individual system. The O debt measured by 12 min. of recovery was lowest with the conveyor system. The conclusion was that the conveyor system for this type of work did not exert any special physical influence upon the organism.—*T. M. Carpenter.*

9579. ENGELMANN, B. Anhaltende Grundumsatzverminderung durch Wärmeeinwirkung. *Arbeitsphysiologie* 2(5): 387-394. 1930.—Male guinea-pigs of 600-800 gm. in weight were studied by means of a Rubner respiration apparatus before and after a 4 to 5½ weeks' stay in a room kept practically constant at 33° C. There was a lowering of the basal metabolism as much as 24%, and this lowering was not only in total metabolism but also on the basis of surface, per gm. of body weight and per gm. of body protein.—*T. M. Carpenter.*

9580. FUJITA, AKIJI. Über den Stoffwechsel der Körperzellen. *Biochem. Zeitschr.* 197(1/3): 175-188. 1 fig. 1928.—The author determined the O consumption and the aerobic and anaerobic glycolytic rate of several kinds of mammalian cells by the Warburg manometric method, immersing the cells in serum instead of Ringer's solution. The following cells were studied: adrenal cells of rats, mice, and guinea-pigs; hypophyseal of rats and mice; testicular, spleen, embryonic lung, embryonic lens, and white bone marrow cells, and sperm, leucocytes, and blood platelets of rats; ovarian, placental, and adult lens cells of mice; epithelial and sympathetic ganglion cells of rabbits. Values for Q_0 at 38° C. ranged from 0 to 13 cu. mm.—*M. Dann.*

9581. GÈNEVOIS, L. Metabolisme et fonctions des cellules. Esquisse d'une physiologie des réactions productrices d'énergie dans la cellule vivante. 120p. Masson et Cie: Paris, 1931. Pr. 26 fr.—Cell metabolism is discussed from the standpoint of the "Pasteur-Meyerhof" reaction; namely, lactic acid and alcoholic fermentations. The first two chapters are a general consideration of this reaction and the remainder of the book is taken up with the metabolism of various animal and vegetable cells including a chapter on tissue culture. Oxidation-reduction mechanisms are not included.—*F. Bernheim.*

9582. GESENIUS, HEINRICH. Über Stoffwechselwirkungen von Gurwitsch-strahlen. *Biochem. Zeitschr.* 225(4/6): 358-367. 1 fig. 1930.—In 68 out of 102 experiments in 4-hr. "mitogenetic irradiation" of the anaerobic fermentation of fluid yeast culture, with yeast-agar culture as indicator, in an N-CO_2 atmosphere, the fermentation was distinctly accelerated; the metabolism was unchanged within the limits of error in 30 experiments, and depressed in 4. In 40 out of 54 experiments the respiration of yeast cells in an O atmosphere (fermentation excluded by the conditions of experiment) was inhibited in a 4-hr. irradiation with yeast-agar culture as inductor; respiration was unchanged within the limits of error in 13 experiments and increased in 1. This seems to testify against a promotion of growth by "mitogenetic irradiation." The question was further tested in 17 experiments by irradiation of yeast cultures which were both respiring and fermenting; both respiration and fermentation were lessened in 16 out of the 17. Yeast ferments were inhibited, in 28 out of 30 cases, by blood from healthy human subjects as inductors.
